Problem of the Cystocele.—In all cases of cystocele complicated with prolapsus uteri sufficient to have an associated retroversion, Ward believes that shortening of the uterosacral and round ligaments is necessary in addition to other procedures. He describes the technic which he has adopted. He combines the principles of several operations. His technic is a combination of the methods of Hadra, Goffe, Martin and Frank, Alexandroff and Sims, with the result of reducing the hernia, replacement of its supports by overcorrection, overcoming the excess of bladder base and vaginal wall both anteroposteriorly as well as transversely, with a restoration of the anterior invagination of the uterus. The operation is termed a cystopexy.

End Results of Resection of Fallopian Tubes.—Of forty-four patients whose cases were analyzed by Bullard, twenty-one have been entirely relieved of symptoms. Twenty cases have been total failures or only partially successful. Only three women have become pregnant.

Localization of Foreign Bodies at the Front.—The "nearest point" method of localization described by Waters was used at the French Evacuation Hospital at Vasseny, France, near the Chemin-des-Dames. This is a palpation method, carried out under fluoroscopic observation, of the soft tissues in the region of the projectile. The palpation of the soft tissues is done with a wooden stick about 10 inches long with a metal screw or tack inserted into each end. This is known as the palpating or "joy" stick. Under the screen the nearly transparent wood can be seen only faintly, while the sharp contrasted shadow caused by the metal screws is plainly visible. The purpose of palpating the soft tissues with this instrument is to determine whether the foreign body can be moved, and how much. By exerting light and deep pressure on the soft tissues with the stick it is possible to determine with fair accuracy the depth at which the projectile lies under the point on the skin surface where the pressure is made. By holding one end of the stick against the skin surface and shifting the tube from side to side, the simple parallax method can be combined, which often helps a great deal in cases where the projectile is embedded in the bone or has entered the joint. Generally speaking a projectile, in the soft tissues, which yields movement by light pressure exerted on the palpating stick, would lie about 2 or 3 centimeters under the skin. If deep palpation is necessary in order to produce movement of the projectile, the projectile lies about 4 to 5 centimeters under the skin. The nearest point method is most applicable to localization of projectiles in the soft tissues of the extremities, the axilla and triangles of the neck, particularly, and also the scrotum and buttocks. In cases where foreign bodies are located in the cranium, chest and abdominal cavities, the nearest point method has its least use. However, in combination with the parallax method used in bones and joints, it will still give the most accurate and quickest evidence in the localization of the projectile.

Influenza Epidemic in S. A. T. C., Los Angeles. G. H. Kress, Los Angeles.—p. 146.

Endocrine Glands and Their Relation to Vasomotor Disturbances of Air Passages, Hay-Fever and Asthma.—Among the twenty-six cases of vasomotor rhinitis seen by Selfridge, fourteen were found with signs of slight endocrine gland insufficiencies. No study was made of the remaining cases to determine the possibility of gland insufficiency. Of fifty-two cases of asthma, twenty-two gave signs of endocrine disturbances, six thyroid predominating, fifteen hypopituitary, one probably status lymphaticus. Gland disturbances in the other thirty cases were not searched for.

*Corpus Luteum in Neurologic Practice. H. Climenko, New York.—p. 1.
*Testicular Hormone. H. Wheelon, St. Louis.—p. 16.
*Paroxysmal Nasal Hydrorrhea Due to Dysthyroidism of Syphilitic Origin. M. R. Castex, Buenos Aires.—p. 29.

Corpus Luteum in Neurologic Practice.—For purposes of control Climenko used corpus luteum in some male neurasthenic cases. It was also administered to patients suffering from organic nervous diseases, such as multiple sclerosis, and also in the early stages of dementia praecox. In all of these the drug was inert. Corpus luteum had no effect on the blood pressure of arteriosclerosis, neither in the male nor in the female. The best results were obtained in young females, poorer results in natural menopause and no results in surgical menopause. The hypodermic preparations did not give as good results as the drug given by mouth. Contrary to the Sajous statement, Climenko found that corpus luteum whenever efficient gives prompt results and large doses need not be employed. He found that 2 grains is as large a dose as one needs to use. Corpus luteum extract acts best when there is every reason to believe that the native corpus luteum is still present. The administration of the extract cannot replace the function of the native corpus luteum in pregnancy and probably also not in menstruation. When menstruation is discontinued by virtue of disturbance in the secretion of another gland, such as the pituitary, corpus luteum will not produce menstruation. Inasmuch as corpus luteum extract when effective produces almost always the same chain of phenomena, Climenko feels that it is reasonable to conclude that (*a*) corpus luteum has a specific action; (*b*) the administered extracts probably do not act as the native hormone; and (*c*) that the extract, in all probability, stimulates the native corpus luteum to function. The two contraindications to the use of corpus luteum are an abnormally low blood pressure and profuse and frequent menstruation.

Testicular Hormone.—That the proper development and functioning of the various organs of the body are dependent on the correlating action of the internal secretion of the interstitial cells is the conclusion reached by Wheelon on the basis of his own observations and a review of the literature. Its presence makes possible normal somatic differentiation. Structural and functional changes of tissues result in alterations of nervous activity, such alterations occurring partly because of somatic alterations and their attended functional changes and partly because of a direct influence on the nervous structure proper. However, it is wrong to assume that the internal secretion of the gonads alone is sufficient to establish and maintain sexual characters, because the influence of the adrenals, thyroid, hypophysis and thymus on the development and maintenance of sex and sex characters cannot be ignored. However, these glands are found well developed in the two sexes while but a single specific primary genital gland is found in each sex. The action of the gonad hormone in the presence of normal endocrine glands and somatoplasm is necessary, therefore, to the development of true sex types.

Nasal Hydrorrhea.—No case similar to the one described by him has been found by Castex in the literature. A woman, aged 40, began to have outbreaks of rhinorrhea in paroxysmal form when about 28 years of age. The attacks occurred at relatively long intervals in the first years, but slowly and progressively became more frequent and acute. The patient was seized at any hour of the day or night, although there was a predilection for the morning and the evening. The attacks began with a sensation as of a sudden cold, with sneezing, followed by an abundant flow of albuminous liquid which lasted between half an hour and an hour. Topical applications, general treatments, dietetic and climatic therapeutics gave not the slightest relief, the attacks on the contrary becoming progressively more acute and frequent, until from one daily they reached in the last two years two or three crises per day lasting progressively longer, up to two and three hours each time. The intensity of the flow also increased and necessitated an average of fifty men's handkerchiefs for each attack. Exploration by Maranon's maneuver disclosed that she had a goiter, distinct, soft, scarcely perceptible to the touch at the level of the isthmus and left lobe, evident at the level of the right lobe, and still more evident throughout the gland.

Treatment was begun with thyroid preparations, and within a few days a favorable effect on the paroxysms of hydrorrhea was apparent. Thereafter the thyroid treatment was intensified. The hydrorrheic attacks became much less, but at the same time the phenomena of hyperthyroidism made their appearance, and their exacerbation was such that the treatment had to be interrupted. Close examination of the patient disclosed a slight anisodischorea and a soft systolic bruit in the aorta. These two elements, suggested the probability of the syphilitic origin of the dysthyroidism—especially since the husband of the patient had formerly had syphilis, treated deficiently, and most of the children showed a taint of hereditary dystrophic syphilis. A mixed antisyphilitic treatment was started, having recourse to the administration of iodin through the alimentary canal, and mercury, through intramuscular injections of 0.02 cgm. of biniodid per day for a month. At the end of a month's treatment, the attacks had almost entirely vanished, threatening only from time to time. The patient was allowed a rest from treatment for three months. The attacks were renewed during the third month. The mercurial treatment was resumed and kept up for three months. At the end of the first month the crises vanished and did not return either during the last two months of mercurial treatment or during the two months rest which have since elapsed.

*Yeast Autolysate as Culture Medium for Bacteria. I. J. Kligler, New York.—p. 183.

Value of Cooked Meat Medium for Bacteria Study.—Holman contends that the cooked meat medium is the most useful medium for obtaining growth of both anaerobic and aerobic bacteria, for storing mixed cultures for later isolation as well as pure cultures for further investigations. It is a medium simply made which can be sterilized readily, and owing to its high buffer character is adaptable to the growth of a great variety of bacteria.

Yeast Autolysate as a Culture Medium for Bacteria.—Experiments made by Kligler, indicate that yeast permitted to undergo autolysis may serve as a cheap substitute for more expensive animal proteins or their digestioin products. The autolysate contains a high percentage of amino nitrogen and a relatively small amount of the higher nitrogen complexes. The fact that some bacteria, notably pneumococcus, meningococcus, etc., do not thrive as well in the yeast broth as they do in beef infusion media, would indicate that the higher nitrogen complexes—polypeptides, etc.—play some part in bacterial nutrition. On the whole, however, it seems that the yeast autolysate media are entirely satisfactory for the cultivation of the less delicate pathogenic bacteria. Endo and brilliant green plates made with this medium give entirely satisfactory results.

Physiology of Endogenous Uric Acid.—The uric acid output of two normal individuals and fifteen other subjects who were convalescents and patients was studied by Höst. In none of the seventeen subjects was the uric acid output for twenty-four hours constant. But with a fixed diet and under similar conditions the uric acid output in a few subjects was constant, while in the majority of those examined it was extremely irregular and showed variations from day to day up to 80 per cent. But even in the individuals whose output of uric acid was most regular, the output was dependent on several factors, of which variations in the diet are the most important. In every increase or decrease of the caloric value of the food beyond a certain minimum, the uric acid output was always changed in the same direction. This took place whether the caloric value was varied by means of protein, fat or carbohydrate; the change in the uric acid output was, however, greater when the amount of calories was varied by means of protein rather than by nitrogen-free food elements. With a constant food caloric value the uric acid output depended to a certain extent on the food protein, so that a change in the latter beyond a certain minimum always produced a corresponding change in the uric acid output. The excretion of nitrogen and the hydrogen ion concentration of the urine were without influence on the endogenous uric acid output. On the other hand, increase of body temperature produced a considerable increase in the uric acid output. The endogenous uric acid output in twenty-four hours varied between 0.27 and 0.99 gm.; the last value is obtained in a normal person on an extensive bread diet. The amount of the endogenous uric acid in the blood varied to a great extent, the minimum being less than 0.50 gm., the maximum being 2.68 gm. per hundred c.c of blood, but is constant in the case of each individual within the limit of error of the method (10 per cent.). In 70 per cent. of the subjects the uric acid concentration is between 0.01 and 0.02 gm. per hundred c.c. of blood.

Inulin in Animal Body.—Benedict's modification of the Lewis-Benedict method was used successfully by Okey for the determination of levulose, and of levulose in the presence of inulin.

Digestibility of Bacon.—A very careful study was made by Blunt and Mallon as to the digestibility of bacon. The coefficient of digestibility of much and slightly cooked bacon fat was found to average 96.7 per cent., approximately the same as that for other soft fat and much higher than the 82.6 per cent. reported by Rubner for bacon eaten in large pieces (raw?). The nitrogen also was as well digested as that of other meat.

Rapid Method for Estimation of Urea in Urine.—The method described by Sumner consists in treating a small quantity of urine (1 c.c.) in a centrifuge tube with an approximately neutral phosphate solution and with urease. After the urea has been decomposed a protein precipitant is added, the tube centrifuged, and an aliquot of the clear supernatant liquid is Nesslerized and compared with a standard.

Gas Tensions of Abdominal Cavity.—The contribution made by Haggard and Henderson consists in the demonstration that the CO_2 tension of the abdominal air soon becomes equivalent to that of the pulmonary alveolar air and of the arterial blood, and that under abnormal conditions (experimental acidosis) in which it is not easy or safe to cause the rebreathing necessary to obtain an alveolar sample, the CO_2 tension in the abdominal air falls in close correspondence to the arterial CO_2 tension. Diffusion of oxygen through the tissues is much slower than in that of CO_2. The tension of oxygen in the abdominal air at equilibrium is about 45 mm. of mercury, much below that of either the arterial or venous blood and corresponding therefore probably to that of the tissues. When the air breathed contains carbon monoxid this gas appears in the abdominal air. The tension of ether vapor in the abdominal air during anesthesia is 29 mm. mercury.

System of Blood Analysis.—The main purpose of the research recorded by Folin and Wu has been to combine a number of different analytical procedures into a compact system of blood analysis, the starting point for which should be a protein free blood filtrate suitable for the largest possible number of different determinations.

Lactalbumin a Complete Protein for Growth.—Emmett and Luros claim that lactalbumin is a complete protein in the sense that it does not lack any of the nitrogenous cleavage products essential for growth. It can supplement a deficient growth-promoting protein (corn gluten) and, incorporated as the sole protein in a ration containing lactose, it produces a normal rate of growth when present to the extent of only 10 per cent.

Studies of Acidosis.—The bicarbonate content of serum or oxalate plasma is determined by Van Slyke and his associates by adding an excess of standard acid (5 c.c. of 0.02 NHCl to 2 c.c. of plasma), removing the carbon dioxid by rotating the solution for one minute about the wall of a flask, and titrating back with 0.02 NNaOH to the original hydrogen ion concentration of blood (p_{H^+} 7.4) with neutral red as indicator.

Problem of Fatigue.—The term "industrial fatigue" is at present loosely applied either to the daily and weekly weariness resulting from industrial work or to the condition of accumulating fatigue which merges insensibly with psychoneuroses. It would seem more logical to Spaeth to restrict the term industrial fatigue to the former more popular meaning and designate the gradually accumulating fatigue in overdriven industrial workers as industrial psychoneurosis. A very extensive bibliography is appended to this article.

Medical Aspects of Telephone Operating.—This paper is based on nine years of service as industrial physician for a telephone company. Richardson discusses the effects of the work on the different parts of the body which may be subject to strain in telephone operating.

Pathology of Epidemic Pneumonia in Camps and Cantonments in 1918.—The forms of pneumonia caused by each organism and the modifications which result from the nature of the predisposing disease, the virulence of the bacteria, the resistance of the infected person and other less tangible factors are described by MacCallum. He emphasizes that the anatomic changes produced by this disease have not been seen by any one: at least they have not been recognized clearly, but every one has realized that the disease produced an extraordinary depression or lowering of the ordinary powers of resistance so that these persons were intensely predisposed to the invasion of any pathogenic bacteria which happened to prevail in their mouths and throats. Pneumonia, therefore, often followed immediately, and all who died showed the pneumonic changes in their lungs, changes which were exceptionally severe and rapidly fatal, on account of the unparalleled spread of the bacteria in the unresisting tissues. But the type of pneumonia was different according to the organism which happened to invade, and it was possible to recognize pneumococcal, streptococcal and staphylococcal forms of confluent lobular pneumonia and to distinguish them from each other and from the interstitial form caused by the bacillus of Pfeiffer. MacCallum says that stress must be laid on the epidemic character of the secondary invasion, which made it appear that in one camp nearly every case was a pneumococcal pneumonia, while in another almost every case was due to the influenza bacillus. It is not surprising that with the one-sided view obtained at first by those who observed these cases in one hospital only, there should have been announced the conviction that the bacillus of Pfeiffer was the cause of the primary disease as well as of the pneumonia. But broader experience has shown, it seems, that this prevalence of the influenza bacillus in some camps, as in those of the New England States, represented a local condition. In other places, pneumococci and streptococci were the opportune invaders, and we are still quite ignorant of the cause of the primary disease.

Tuberculosis in Children.—At the Oklahoma City Tuberculosis Dispensary 135 children were examined during 1918. Of these, 50 gave a history of exposure to open cases, 70 were exposed to suspected cases and 15 gave no history of exposure. One hundred and sixteen gave a history of measles, 50 had pneumonia, 34 had influenza and 86 gave a history of whooping cough. A history of the following symptoms was obtained: cough in 59 cases; expectoration in 29; pain in the chest in 24; pleurisy in fourteen; hemoptysis in 2; night sweats in 11; loss of flesh in 25; loss of strength in 34; hoarseness in 17; fever in 19; loss of appetite in 28; disturbed digestion in 27. Physical examination revealed the following: weight below standard, 73; height below standard, 17; general appearance good in 95, fair in 48, poor in 21. Type of chest normal in 121, abnormal in 14; superficial lymph nodes palpable in 110 (some were not reported); tonsils hypertrophied in 80, dulness elicited by percussion in 89 (with few exceptions the dulness was interscapular); D'Espine's sign was present in 35; râles in 29. Sixty-nine were examined roentgenographically and the roentgenogram showed tuberculosis of the tracheobronchial glands alone in 11 cases; tuberculosis of the tracheobronchial glands with peribronchial thickening in 29; tuberculosis of the tracheobronchial glands and peribronchial thickening, with involvement of the lung tissue in 19; nontuberculosis infection in 3. The diagnosis as recorded in the 135 cases was: tuberculosis of the hilus alone in 34; tuberculosis of the hilus with peribronchial and lung involvement in 44; doubtful, 40; cases with nontuberculous infection, 5; negative, 12.

*Bilateral Maximum Blood Pressure in Pulmonary Tuberculosis. R. J. Cyriax.—p. 73.
*National Scheme for Prevention and Treatment of Tuberculosis. H. G. Sutherland.—p. 77.

Bilateral Maximum Blood Pressure in Pulmonary Tuberculosis.—One hundred and sixty bilateral readings were taken by Cyriax from twelve patients hospitalized because of tuberculosis. Tubercle bacilli had been found in the sputum of every case; six patients had unilateral, and six bilateral disease; ninety-eight observations were made on the former, and sixty-two on the latter. The readings were taken with a Riva Rocci apparatus by the method of auscultation, the maximum pressures being checked in addition by palpation of the pulse. As a general rule the first reading was taken from each arm alternately. The vast majority of observations were made while the patients were actually in bed. Purely for the sake of convenience in description, the term "lesion pressure" has been adopted by Cyriax to denote the maximum pressure in the brachial artery of the arm on the diseased side, the term "standard pressure" to denote the corresponding pressure on the healthy side. Forty-seven of the ninety-eight observations made in unilateral cases of disease revealed differences of more than 5 mm. between these two pressures. In patients suffering from an acute spread of the disease, stained sputum or hemoptysis, the lesion pressure was found, as a rule, to be higher than the standard pressure, the difference between them amounting in some cases to 26 mm. This rise in the lesion pressure appeared to be solely an index of an acute process, and was not always associated with pyrexia; in some cases of stained sputum, it preceded the actual staining by some days. Subsequently, as the more acute stage passed off, or staining ceased, the lesion pressure was noticed to fall below the standard pressure. But the latter usually rose at the same time, and hence, when the observations were recorded graphically, the curves representing the two pressures were seen to cross. A rise in the lesion pressure above the standard pressure has thus been found, as a rule, to be an accompaniment of symptoms of activity; a fall, on the other hand, to be of favorable import. Thirty-five of the sixty-two observations made in bilateral cases of disease revealed differences of more than 5 mm. between the maximum pressures in the two arms. But the results were not very satisfactory probably because in cases of bilateral mischief both pressures were "lesion pressured," and changes in one were therefore apt to be marked by changes in the other. Nevertheless, the pressure variations were found to correspond fairly closely with those found in unilateral cases.

National Scheme for Prevention and Treatment of Tuberculosis.—At a conference called by the Tuberculosis Society of the United Kingdom in January, 1919, certain resolutions were adopted: That a special department of the ministry of health in each country be created for the prevention and treatment of tuberculosis. The department of tuberculosis thus constituted would be responsible for general administrative measures against tuberculosis throughout the countries concerned; for statistics relating to the disease; to suggest, advise, direct, and if necessary finance schemes of after-care and employment of tuberculous patients; to direct, to finance, and to supervise an educational program by means of lectures, traveling exhibitions, appropriate cinema films, and by any other means; to direct and to finance research work in relation to the disease; to study housing and conditions of work in relation to the incidence of tuberculosis, and to promote legislation dealing with this matter; deputy commissioners of tuberculosis appointed by the crown work under the direction of the commissioners. Tuberculosis officers should be appointed throughout the kingdom.

*Ten Thousand Recruits with Doubtful Heart Conditions. S. R. Wells. —p. 510. To be concluded.
Plea for Homogenous Nerve Graft. E. W. Fisher.—p. 514.
Hyperpyrexial Heatstroke. K. G. Hearne.—p. 516.
Stock Vaccine in Pneumonia. W. F. Haultain.—p. 517.
Health Resorts and the States. C. W. Buckley.—p. 517.

Doubtful Heart Conditions in Recruits.—Out of the 10,000 recruits examined, 307 were considered to be definite examples of aortic regurgitation. In many cases there was reason to believe that other lesions were present as well. In ninety-four cases only the aortic lesion was present; in fourteen cases aortic stenosis was associated with it; in 112 cases, both aortic and mitral regurgitation were present, and in thirty-three cases, aortic and mitral regurgitation and mitral stenosis existed. One hundred and sixty-two men gave a history of rheumatic fever and symptoms of aortic regurgitation, 145 aortic regurgitants gave no history of rheumatic fever, while 1,759 men had a history of rheumatic fever but no evidence of aortic regurgitation, and 7,934 gave no signs or history of either. Fifty-five gave a history of rheumatism, and twenty stated that they had had chorea. Sixty-six men gave a history of tonsillitis. Seventy-one gave a history of scarlet fever. Twenty-two gave a history of diphtheria. The proportion giving a history of pneumonia is not large; twenty men had had pneumonia and 142 gave a history of one or more attacks of influenza.

Pathogenesis of Deficiency Diseases; Pellagra. P. Rondoni.—p. 542.
*Doubtful Heart Conditions. S. R. Wells.—p. 544.

Doubtful Heart Conditions in Recruits.—The conclusion of this investigation leads Wells to believe that two important causes of aortic regurgitation in the cases we have investigated—that is to say, men between the ages of 18 and 41—were rheumatic fever and strain. The investigators were unable to find any definite correlation in these cases between syphilis, tonsillitis, scarlet fever, diphtheria, pneumonia, gonorrhea, or growing pains, and the evidence is against influenza. With regard to chorea, there is a suggestion in some of the results that it may be a cause, but the number of cases investigated was so small, and the proportion of them giving a history of rheumatic fever as well so large, that caution must be exercised in drawing deductions. With regard to a history of "rheumatism," there is some evidence for assuming that in a certain proportion of these cases, but not all, an affection of the same nature as true rheumatic fever was referred to.

Cerebrospinal Fever: A Review. H. Rolleston.—p. 25.
*Filarial Infection in Macedonia. J. G. Forbes.—p. 654.
Study of Epidemic "Spanish Influenza." E. Folley.—p. 656.
*Gas Gangrene, Due to Infection with Bacillus Tumefaciens. W. J. Wilson.—p. 657.

Filarial Infection in Macedonia.—Forbes reports two cases of *Filaria conjunctivae* (Addario) in man, with the first recorded discovery of the male worm. Records of six examples of human infection exist and in every case the solitary female worm, usually immature, only has been found. The two patients, one of whom had had 18 months' service in Macedonia, had not previously been out of England; the other a Serbian, came under treatment at the same general hospital attached to the Royal Serbian army. The male worm was found accidently in a lump, the size of a filbert nut, on the outer side of the upper part of the left forearm, which had been intermittently swollen for the previous two months. The nodule from which the worm had been removed was examined in the fresh state, but failed to show the presence of a second or female worm or evidence of microfilariae in the wall of the cystic interior. Examinations of the patient's blood were made on several occasions, both by day and night in fresh and stained films, but failed to show the presence of any microfilariae and gave no evidence of leukocytosis. The second patient had a tumor on the right side of the nose, which had given rise to inflammatory swelling of the face below the orbit for the previous two months. At operation a small cyst was removed and found to contain opaque glairy fluid and a delicate filiform worm. Blood film examinations of the patient on two separate occasions failed to show any microfilariae.

Gas Gangrene Due to Infection with Bacillus Tumefaciens.—A new pathogenic anaerobe was isolated by Wilson from a case of gas gangrene. Animal experiments confirmed the identity of the organism. The *B. tumefaciens* is an actively motile gram-positive bacillus. In morphologic characters it resembles the *Vibrion septique*, but it is easier to cultivate and forms spores, especially in carbohydrate media, with the utmost facility. It is essentially a saccharolytic bacillus and fails to digest either coagulated egg albumin or serum. In litmus milk it produces acid and gas. The clotted casein is not digested and remains red in color, i. e., there is no bleaching. Spores were found in the milk culture. The deep colonies in 0.1 per cent. glucose agar resemble those of the *V. septique*. In fermenting saccharose, inulin, and glycerine it resembles some strains of *B. welchii* and differs from *V. septique*, but resembles the latter in fermenting salicin. It is far more active in its action on sugars than the two strains of *B. oedematiens* with which Wilson compared it. In meat broth culture the fragments of muscle become pink in color and no digestion occurs. It hemolyses red blood cells.

*Psychology of Internment. A. L. Vischer.—p. 696.
Gunshot Wounds and Other Affections of Chest. C. MacMahon.—p. 697.

Vaccine Treatment of Influenza.—The vaccine used by Russell was that manufactured by the Edinburgh Royal College of Physicians' Laboratory. There was no ill effect from its use, in fact, it seemed that the patient's general condition improved, that the intoxication seemed to be lessened or restrained. No patient has died to whom the vaccine has been given. Russell believes that in capable hands vaccine therapy seems to be the most promising line of treatment, if adopted as soon as definite respiratory signs appear, and if pushed with judgment.

Experimental Studies with Small Doses of Roentgen Rays.—Experimental facts as to the effects of small doses of roentgen rays on the blood of rats and on the susceptibility of these animals to tumor implantation (Jensen's rat sarcoma) are recorded by Russ and others. An attempt is made to show the possible bearing of the salient features of these newly acquired facts on the present day treatment of malignant disease by means of roentgen rays. Two suggestions are put forward in this connection. When a therapeutic dose is given to the cells of a tumor the rest of the body receives a fractional dose of the rays. It is submitted that the action of these rays, especially on the lymphocytes in the circulation, may be deterrent to the combative forces which the patient can normally bring to bear against the tumor growth. In the second place the possibility of increasing the resisting powers of the system by means of small doses of roentgen rays is shown to have an experimental basis.

Psychology of Internment.—Careful observations of prisoners of war in Switzerland, lead Bing and Vischer to describe a very characteristic psychoneurosis to which has been given the symbolical title of "psychose due fil de der barbelé," in German "Stacheldrahtkrankheit" and in English "barbed wire disease." This name seems to have originated in Switzerland, though its exact origin cannot be certainly determined; it has established itself so thoroughly that already it is to be found in international treaties. The symptoms of a neurasthenia *sui generis* are recognizable in most of those who have lived for more than six months behind the barbed wire fencing, and which in about 10 per cent. of all prisoners reach a high level of intensity. The first sign to appear is an increase of irritability. There is a great deal of quarreling. The power of concentration is greatly diminished. The prisoners complain with striking constancy that they lose their memory of people and of places, in so far as these relate to prewar events. Among the secondary symptoms are insomnia. Some prisoners complain of diminished vision. Many of them grow very suspicious. All have a marked tendency toward pessimism, and see every incident of their daily life in the gloomiest light; the worst cases often go for three or four days without speaking a word, plunged in a kind of torpor. Sexual impotence is very common. All these symptoms, once they are established, generally remain stationary, and rarely diminish so long as the internment lasts. Disturbances of memory, especially amnesia, are very marked. See also abstract p. 40.

War Injury from Signal Lights. W. J. Rutherford.—p. 741.
*Lung Puncture in Treatment of Influenzal Pneumonia. M. Benaroya.—p. 742.

Significance and Surgical Value of Certain Abdominal Reflexes.—Ligat emphasizes that no abdominal examination is complete unless, in addition to other clinical methods, a thorough investigation of the abdominal reflexes has been made and the results carefully noted. The skin and subcutaneous tissue are grasped firmly between finger and thumb and drawn away from the deeper layers of the abdominal wall. If an abnormal reflex is produced it is at once recognized—the patient winces, he may even cry out if a sharp response is elicited. Mackenzie has pointed out that pain is the only sensory reflex evoked in visceral disease. It follows, therefore, that all pain, except that caused by peritonitis, of which a patient complains, or tenderness that an observer may elicit, is due to a true viscerosensory reflex, and not in any way to pain or tenderness felt in the viscus itself. A pinch, which in a person with a spinal cord of normal tone would not have given rise to pain, now does so, on account of the stimulus due to the pinch being received by a part of the cord kept in an irritable condition by undue stimuli from a diseased viscus.

The severity of the pain produced varies widely. Usually when there is general evidence of acute inflammation of a viscus the pain produced by pinching is severe, and may be elicited over a long narrow vertical band of skin; this hyperalgesic band may correspond to parts of one, two, or even three spinal segments, but by careful discrimination of the point of maximum hyperalgesia the actual organ affected can be determined in most cases. In other cases, mostly those of a chronic nature, in many of which the patient has been complaining of vague abdominal pain only, and probably quite unable to indicate its precise locality, very careful examination is necessary, the facial expression being closely watched when the skin and subcutaneous tissue are pinched. It is in these cases that this method of examination is said to be especially valuable, for, by so examining, one is virtually converting a subjective symptom into an objective sign, and in many chronic cases this is the only sign which can be demonstrated and which indicates the actual organ at fault. Sometimes actual pain is not produced, the sensation being evidently difficult to define and described as unpleasant, curious, different from other places, and so on. In all positive cases a departure from normal sensation is evident. This method of examination separates the abdominal organs for clinical purposes into two sets: 1. Lateral: Gallbladder, appendix, fallopian tube. 2. Central: Stomach, duodenum, small and great gut. Illustrative cases are cited and the whole question is discussed at great length.

Spinal Injury with Retention of Urine.—The very large number of deaths from ascending infections after catheterization renders it essential to endeavor to discover some other method of relieving the retention in cases of spinal injury. The observations made by Vellacott in sixty-six cases leads him to conclude that passive treatment, i. e., allowing distension and overflow to take place—should be given a thorough trial, and attempts at expression should be made from time to time. Assistance may be found in the administration of drugs, especially morphin, the application of heat, etc. When dribbling of urine commences, expression is usually quite easy and the bladder can be emptied partially at regular intervals. This diminishes the stretching and thinning of its walls and should allow its muscle to recover tone more rapidly. If complications of the injury (hemothorax, etc.) make it advisable to relieve the distension, temporary paralysis of the sphincter by instrumental stretching may be tried. Even moderate stretching renders expression a simpler and easier proceeding in the earlier and spasmodic stages of retention. It is of the greatest advantage that the treatment of the bladder from the date of injury until the automatic stage is reached should remain in the hands of one person.

Treatment of Gonorrhea.—Gibson is impressed that the earlier the treatment the better the chance of recovery and the less likelihood of complications. The ideal is to combine local curative treatment with general treatment to build up the patient's resistance to the disease. For local treatment one should employ irrigations with as nonirritating and at the same time as potent an antiseptic as possible. Irrigation is to be preferred to syringing, as with an irrigation it is possible not only to use a larger volume of fluid than with a syringe but also to dilate the urethra to a greater extent, and so open out the various folds and crypts in the mucous membrane and drive the entrenched organism from its dugout. Care should be taken to avoid driving back infective material to the posterior urethra, either by complete irrigations or by use of instruments, early in the disease. The best antiseptic on the market in Gibson's opinion is flavine in strengths of 1/6000 to 1/8000. The best way of building up the resistance is with vaccines, given in large and constantly increasing doses. Medicines are useless, except to alleviate certain symptoms, such as dysuria, when they occur.

Lung Puncture in Treatment of Influenzal Pneumonia.—The treatment described by Benaroya has been employed in a series of forty-one patients, many very seriously ill. Their ages ranged from 10 months to 68 years and the patients showed all degrees of resistance. This treatment aims at determining a local accumulation of polymorphonuclear leukocytes, and so stimulating phagocytosis, by setting up a focus of irritation in the pneumonic areas. It is an application to the lung of the principle advocated by Kraske, in the local treatment of erysipelas. It may be considered analogous to laparotomy in the ascitic variety of tuberculous peritonitis. The first step is to determine accurately the situation and area of the consolidated patches. A hollow needle or trocar about 2 inches long is then introduced in the direction of the patch and allowed to remain in the lung for about thirty seconds. If more than one patch has been detected it is preferable to select the largest and to neglect the others. If the base is entirely affected, as in lobar pneumonia, or several patches of considerable size are present, a second puncture may be necessary. It was rarely needed to repeat the puncture in the above series of cases, and then only for exacerbation of the morbid process. Strict asepsis is essential. As regards the seat of election, the axillary or scapula lines are, if possible, to be preferred. As this method does not depend on the type of organism responsible it may be tried in every variety of pneumonia, influenzal, pneumococcal or even septic, following a trauma. The results in all these varieties have been favorable. A steady fall of the temperature is always to be expected, and in many cases it becomes normal in twenty-four hours.

Enuresis Cured by Electrical Methods.—Almost all cases of enuresis, both in adults and children, Johnson has found to be amenable to the application of rhythmically interrupted sinusoidal or faradic current through the region of the bladder for fifteen minutes daily for a period of two to four weeks. Johnson stimulates the prostate, using a small test tube filled with water and corked. Through the cock is thrust a stiff wire, having a loop on the outside for attachment to the lead from the solenoid. The best tube is vaselined and introduced about 2 to 3 inches into the rectum. It is connected with the generator and the high-frequency current turned on for fifteen minutes. The treatment is given daily.

Common Causes of Persistent Headache and Their Differential Diagnosis.—Clarke urges that inasmuch as headache is only a symptom the cause should be sought for. He mentions cerebral tumor, eyestrain, chlorosis, nephritis, diabetes, toxic or infective states apart from specific fevers, alcohol, lead and syphilis, all probably giving rise to the pain by their direct vasomotor action on the cerebral or meningeal vessels; arteriosclerosis, hyperpiesis, meningitis, migraine and neurasthenia. Having once established the diagnosis, the case must be considered on its own merit as to treatment.

*Paralytic Form of Rabies. P. Marie and C. Chatelin.—p. 428.
*Transmission of Rabies to Fetus. P. Remlinger.—p. 437.
Carbon Monoxid Poisoning. V. Balthazard.—p. 439.
Sterilization with Formaldehyd. Barthélemy and G. Gross.—p. 441.

Paralytic Rabies.—Marie and Chatelin report the necropsy findings in a boy of 11 who developed symptoms suggesting poliomyelitis, a rapidly acute ascending paralysis, fatal in a few days. The child had been bitten on the upper lip by a dog five weeks before, and a period of extreme agitation and screaming had preceded by ten days the paralysis in the legs. Necropsy disclosed acute infiltration polio-encephalomyelitis, with the typical findings of rabies, confirmed by inoculation of rabbits. Rabies has been found in 218 dogs, two cats and one horse, since Jan. 1, 1919, in the Seine district.

Transmission of Rabies to Fetus.—Remlinger reports some striking experimental experiences which confirm Konradi's statements in 1916. Animals inoculated with rabies may not display any signs of the disease for from one to three months, while their young born in the interim present rabies and may have died before the mother shows any signs of the disease. Remlinger relates that one guinea-pig thus developed rabies 122 days after the inoculation, sixty-eight days after the casting of the litter, and thirty-eight days after the death of the last one of the young. In Konradi's guinea-pigs, rabbits and bitches the interval sometimes was over a year before the animal succumbed to the rabies that yet it had transmitted to its young in the uterus. These facts throw light on cases in which rabies has been transmitted to man by an apparently healthy animal; it may be harboring the rabies virus in its blood. Young animals may be apparently healthy and yet they may have been infected in the uterus, and they may develop rabies at any moment without further contact. The fact that the young dog or other animal has never had a chance for being bitten, thus does not exclude the possibility of rabies. The experiences related suggest also that possibly the fetus might become immunized by minute amounts of the rabies virus traversing the placenta. In conclusion he suggests further the possibility that the rabies virus might in certain cases induce other clinical pictures than typical hydrophobia or paralytic rabies. We know that it may induce Landry's paralysis, and it is possible it may be responsible for certain other forms of acute mania, etc.

Meningitis in Influenza. M. Capitan.—p. 468.
Injectable Solution of Mercury Benzoate. E. Léger.—p. 473.
*Treatment of Paroxysmal Tachycardia. C. Fiessinger.—p. 476.
*Stereoscopic Roentgen Plates. Chabry.—p. 480.
*Prison Camp Undernourishment. C. Richet, Jr., and M. Mignard.—p. 481.

Cure of Paroxysmal Tachycardia.—Fiessinger declares that it is possible to arrest an attack of paroxysmal tachycardia by impeding the entrance of air, compelling respiratory effort. One woman of 40 with pulse of 200, cyanosis, the extremities cold and the chest crowded with râles seemed moribund, but she recuperated at once when forced to breathe through an apparatus (Pescher jar) which required a respiratory effort. One man always found relief in the paroxysm by running after his auto. Later, Nature came to his aid with asthma, the paroxysms subsiding when an attack of asthma supervened, the pulse then keeping slow for forty-three hours. Another man of 51 has the attacks of paroxysmal tachycardia come on while he is walking. He then starts to get over the ground very much faster, and this always aborted the attack in his experience with ten paroxysms. In the case of one young woman, the paroxysm of tachycardia had lasted for twenty-four hours, not modified by various measures, including pressure on the eyeballs. Finally she began to do breathing exercises, and at the second deep inspiration the paroxysm was arrested. A month later the paroxysm returned when she was in the street. She stopped and took three deep breaths, exhaling very slowly. The paroxysmal tachycardia subsided immediately. Fiessinger declares that any respiratory effort, inhaling or exhaling, kept up long enough will arrest the paroxysm of tachycardia. The only thing is to breathe deep and to be strong enough to do this. A professor at the Sorbonne developed paroxysmal tachycardia during convalescence from a fever, but he was too weak to breathe deep, and compression of the eyeballs had no effect. He died the next day. A fatal outcome was also the rule when the patients had been taking drugs to combat fever. Fiessinger saw two cases of the kind in patients convalescing from influenza. The pulse ran up to 190 or 200 and the patients were unable to make the effort to breathe deep. Each had taken three or four doses of acetylsalicylic acid. The effort of vomiting may arrest paroxysmal tachycardia the same as the effort of breathing deep, but the latter is simpler and easier, and its effect is amazing, he reiterates.

Stereoscopic Roentgenography.—Chabry describes a simple method with which it is possible to get the stereoscopic effect on a single plate.

The Undernourishment in the Prison Camps in Germany.—Richet and Mignard relate that repatriated civilians and soldiers frequently present a combination of symptoms suggesting those of actual starvation plus those of deficiency diseases. Emaciation, anemia and diarrhea dominate the clinical picture. Hypertrophy of the liver is common, and the skin shows numerous infectious lesions while the aspect of certain bones and joints recalls that of rachitis in children. Bradycardia is frequent, as also polyuria with pollakiuria, irritable asthenia, and modifications in the reflex responses.

Paralysis of Sympathetic Accompanying Aneurysm in the Neck. L. Lortat-Jacob and G.-L. Hallez.—p. 137.
*Curable Alcoholic Cirrhosis. H. Dufour and Le Hello.—p. 143.

Curability of Cirrhosis of the Liver.—Dufour and Le Hello assert that syphilitic cirrhosis of the liver is not the only form of cirrhosis that may prove to be curable. They here report two cases for which alcohol was undoubtedly responsible, and yet a clinical cure was realized under diuretics and tapping alone. The male patient was 51, and in four months he was tapped sixteen times, withdrawing an average of 16 liters each time. The woman of 50 was tapped twenty-five times within eighteen months, evacuating a total of 400 liters. Both patients have been apparently cured for over five years. No mercury or iodid was given.

*Fracture of Femur. E. Desmarest, G. Caldéron and M. Cañas.—p. 201.
Inter-Allies Conference on Aeronautics. G. Guillain.—p. 203.
*Treatment of Lagophthalmos. R. Leriche.—p. 205.
*Premonitory Signs of Epileptic Seizure. P. Hartenberg.—p. 205.
Gasoline Treatment of Scabies. F. Lévy.—p. 206.

Subtrochanter Fracture of Femur.—Desmarest and his co-workers state that the usual methods of treating fracture of the femur give deplorable results when applied to fracture in the subtrochanter region. This requires special measures, as they describe in detail. The main point is to apply continuous extension with bilateral abduction. Their illustrations show the principles involved and the best means to apply them.

Treatment of Lagophthalmos.—Leriche remarks that certain men with facial paralysis as the result of war wounds are particularly incommoded by the permanent inability to close their eyelids. Muscle transplantation may remedy this in some cases but is impossible in others on account of destruction of tissue. In this latter group of cases he has attacked the problem in another way; namely, by section of the cervical sympathetic which is followed by retraction of the eyeball and narrowing of the space between the lids, and thus effectually combats lagophthalmos. He has applied this method in one case of facial paralysis dating from 1915, and the man can now close his eyes as if by volitional control, and he is *enchanté* with the result, especially as the previous intense lacrimation has subsided likewise. The operation on the cervical sympathetic was by the same technic as for exophthalmic goiter.

Premonitory Signs of Epileptic Seizure.—Hartenberg discusses the sensations: chilliness, pruritus, tickling in one nostril, neuralgia and other sensory disturbances which may herald the approach of the seizure; also the circulatory signs, the motor, visceral and secretory, and the psychic signs which warn of the impending seizure. Besides these generally known premonitory signs, he calls attention to certain phenomena in some of his patients which herald a seizure. In one, the eyes grow more brilliant and the glance fixed and strange; in another, only one eye shows this change. In one child of 4, the pupils become extremely dilated; one adult sees a spark constantly floating in front of his right eye for two days before the seizure. Another has convergent strabismus come on, and in another the seizure is preceded by the whole face being twisted to the right side. In two women, the nose becomes very red a few days before the crisis; in another, merely the nostrils grow red. In one man, the ears grow red, especially the left ear, the side of the severest spasms. One man's cheeks grow blue, and another perceives a pulse in the epigastrium just before the seizure comes on. Another man sweats profusely on the days the seizures impend. Another epileptic has chronic coryza with profuse discharge but on the day or two preceding a seizure this discharge dries up, and the man is constantly rubbing his nose. There is a constant rise in temperature of half a degree C. during the days preceding the seizure in three women of 18, 68 and 69. One feebleminded boy of 8 announces the approaching seizure by beginning to tell of grandiose schemes for the future. The ages of the patients range from 4 to 73 years. By heeding the premonitory signs, the epileptics can be saved mishaps from seizures occurring unawares, and by compiling a complete list of the prodromes light may be thrown on the nature of the seizures, and possibly means of warding them off discovered.

Influenza at Lausanne.' B. Galli-Vallerio.—p. 1.
*Hysteria or Pithiatism? F. Naville.—p. 13.
Ileus from Plum Stones Arrested by Cancer. H. Maillart.—p. 44.

Hysteria or Pithiatism?—Naville criticizes Babinski's doctrine of pithiatism as incomplete and misleading, and describes a case which is peculiarly instructive. The girl of 15 had been having for several years frequent and prolonged narcolepsy, convulsions, intermittent chorea, occasional slight mutism and functional paraplegia, with a whole train of nightmares, insomnia, paroxysmal headache, vertigo, anorexia, diverse algias, tremor, tachycardia and functional disturbances in vision, in short, an authentic case of *grande hystérie*. The whole seemed to be based on an emotional shock dating from seven years before which had been totally forgotten because it had been thrust into the subconscious sphere by the initial hysteric crisis. As soon as this emotive traumatism had been brought back to the girl's consciousness, the whole train of secondary symptoms cleared up and disappeared spontaneously, and the other functional symptoms progressively improved. There was no erotic factor evident in the case. The emotional shock to which Naville ascribes the hysteria was the disappearance of a young brother and the false news that he had been run over by an automobile. The girl has been apparently completely cured during the year or more since, having had no return of nervous troubles even during the bombardment of the city.

*Infant Mortality in East Africa. P. Sick.—p. 158.

Lymphangitis and Lymphadenitis with Septic General Infection.—Fessler discusses tendon sheath phlegmons, felons, etc. He says of panaritium that there is scarcely any other common affection in respect to which so many sins are committed as this. The fate of the member, even life, may depend on its correct management. He warns not to wait for manifest suppuration but to cut down at the most painful spot to relieve the tissues from pressure. It is easy to determine the most painful spot by testing with the head of a probe, then cutting down to the tendon sheath the entire length of the finger. He advises blocking both the lateral nerves at the base of the finger under a tourniquet, as this shows up the wedge-shaped encroaching necrosis of the cellular tissue. This plug must be cut out to leave the focus gaping. If the stage of necrosis and suppuration has not been reached, the incision may prevent the death of the tissues. This is the only way to keep the infectious process from spreading. Antiseptic dressings, baths and hyperemia treatment aid in the healing of the focus. The suction bell helps to draw the necrotic plugs out of the felon, and the stasis hyperemia checks the lymphangitis. The dressings must be loose so as not to impede the outflow of pus. In speaking of gas phlegmons, Fessler warns that the heart must be kept stimulated but not with digitalis, as the toxins of the gas bacillus already have a depressing influence on the pulse.

Detachment of the Retina.—Birch-Hirschfeld reviews experimental research and clinical experiences with 142 cases of detachment of the retina between 1900 and 1910, with reexamination of most of the patients later. With spontaneous detachment of the retina, seen early, he applies in treatment bed rest, injection of saline and other mild measures, hoping for spontaneous reposition of the retina. If no or very insignificant improvement is observed, he proposes operative measures if the detachment affects the lower part of the retina, if the refracting media are clear enough for ophthalmoscopic supervision of the operative procedures, and if the pressure in the eye is not too much reduced, and there is no extensive tear in the region where it is proposed to operate. The functional capacity of the detached and the still adherent retina must be such that appreciable improvement is possible. The relatively slight chances for success must be fully explained to the patient beforehand. The first thing to be done is to remove the subretinal fluid. For this he prefers to trephine, cutting out a small disk, 1.5 to 2 mm. in diameter, and then aspirating the fluid. The retina can be seen then returning to its place, and with a compressing bandage it can be held in place, hoping it will become reattached. This actually did occur in 5 of 25 patients thus treated, and slight improvement was manifest in 5 others, but in 15 the progressive course of the detachment was not checked. Better results were obtained when he injected a fluid into the vitreous body to exert pressure on the retina. Various fluids have been used for this purpose, but he thought that the logical fluid for the purpose was the fluid he had just aspirated from back of the retina. As this fluid usually contains much albumin, up to 26 per thousand in his cases, he diluted it with a little saline, and thus could inject a somewhat larger volume than he had aspirated. He has applied this procedure in thirteen cases, all quite severe, refractory to milder measures, and comparatively favorable results were realized. In six of the cases there was more or less inflammation in consequence, in the interior of the eye, and this may have contributed to the favorable outcome as five in this group of patients were essentially improved. At the same time it worries the physician to behold this inflammatory process develop in a previously noninflamed eye, as exact dosage of the irritation and guarantee of its harmlessness are out of the question. Consequently in his later series he has restricted his intervention to trephining, aspiration and the compressing bandage. A spontaneous cure has been known in only about 1 per cent. of the cases of detachment of the retina on record. Mild measures were successful in about 5 per cent., and slight improvement was realized with them in 6 per cent. In 89 per cent. they failed completely. Puncture with or without electrolysis and section realized essential improvement in 4 per cent., slight improvement in 25 per cent. and no benefit in 71 per cent.

Silver Salvarsan.—Delbanco comments with enthusiasm on the new and supposedly more harmless salvarsan preparations which are now being made. He has applied silver salvarsan in 120 cases, making a total of 550 injections, all on outpatients, and has never witnessed any untoward manifestations. Only in five cases was there a tendency to transient congestion in the head, but these patients were soon able to go home alone. He cites as important Kolle's recent statement that colloidal silver alone has a pronounced action on syphilis in the rabbit. He suggests further that the way in which the spirochetes take silver stains seems to indicate some special affinity for silver. He remarks parenthetically that it is inexplicable why the glass syringes seem to suffer from the silver salvarsan notwithstanding the colloidal character of the solution. Experimental syphilis in the rabbit has been very successful recently, even to spontaneous coitus chancres on the male rabbit. The blood of a syphilitic in the primary period, even without a positive seroreaction, injected into the rabbit testicle induces a typical primary lesion swarming with spirochetes; syphilis is thus a clinical septicemia from the very first. He adds that silver salvarsan in a dose of 0.2 gm. banishes the spirochetes from the primary lesion when examined against the dark field microscope. With half this dose, the spirochetes return the next day. He emphasizes the prompt subsidence of the florid symptoms of the first and second period under silver salvarsan in his cases; it was combined with mercury in the majority. For a single course of treatment, only from 1 to 1.4 gm. of the silver salvarsan are required. (Its official name is Silbersalvarsannatrium. Kolle says of it, "The maximal effectual dose, 0.2 or 0.3 gm., is below the threshold of danger as the arsenic content of silver salvarsan is scarcely two thirds of that of old salvarsan". . . . "The silver acts chemically as a catalyzator of the arsenobenzol molecule, and biologically as the reenforcer of the specific action of arsenic on spirochetes." He ascribes the action of mercury in syphilis merely to its rendering the tissues toxic so that the spirochetes are unable to thrive in them. He says further that the spirochetes disappear in syphilis in the rabbit in a few days after injection of 0.03 colloidal silver per kilogram, and the primary lesion soon heals. Experiments with syphilized rabbits recently have shown that the intervals between doses as well as the size of the dose have a bearing on the effect of any of the drugs tested.)

Percussion of the Skull in Diagnosis.—Koeppe states that he found a high tympanitic note and cracked pot sound on percussion of the skull of children with abnormally high pressure on the brain from different pathologic processes, brain tumors, etc., and especially with miliary tuberculosis, meningism, otitis, and sometimes with high fever, pneumonia and influenza. As the pressure was reduced under lumbar puncture the tympanitic resonance grew less. In two cases of incipient tuberculous meningitis, this tympanic resonance was the first and for a long time the only symptom.

Nephrectomy and Treatment of the Diseased Mate.—Zondek reiterates that if the functional tests show good functional capacity, even in a diseased kidney, removal of the other kidney is justified when indications call for this. He describes three cases which show how apparently irreparable conditions may be remedied. In one case one kidney was functionally useless and the other ureter became obstructed with sand. He succeeded in dislodging the sand with the ureter catheter and rinsing out the kidney, restoring clinically normal conditions on this side.

Infant Mortality in East Africa.—Sick in commenting on the recent death of J. Dannholz, a missionary in East Africa who had taken a partial medical course, states that by his efforts the infant mortality in his district had been reduced from 75 to 13 per cent.

*Operation for Varicocele. E. Lay.—p. 429.
Enteroptosis. A. Cantilena.—p. 429.

Magnesium Sulphate in Treatment of Chorea.—Cavalieri reports gratifying success from subcutaneous and intramuscular injections of a 25 per cent. solution of magnesium sulphate in a case of extremely severe chorea in a boy of 13. The first symptoms had been noted twelve days before. The solution was made with 4 gm. of magnesium sulphate in 16 gm. distilled water, the dose of 2 c.c. was injected two or three times in the course of the twenty-four hours. The total amount of the drug thus given daily was 1 gm. in this case, and the child was able to sleep at night. The excitement and restlessness had prevented sleep before, and the boy had had to be tied to prevent serious injury from his spasmodic jerkings. By the end of the month he was able to feed himself, and was quite restored in six weeks although left with mitral insufficiency. The magnesium injections were kept up for twelve days.

Quinin and Influenza.—Vico reports another instance of influenza sweeping down on a hospital and prostrating nearly every one connected with the hospital except the 400 malarial inmates under the influence of quinin.

Varicocele.—Lay cuts the middle part of the venous plexus between two ligatures and fastens the stumps together again like the barrels of a gun, fastening the peripheral stump to the external inguinal ring and the other stump to the base of the peripheral stump close to the testicle.

Pathogenesis of Bacillary Dysentery. G. Costantini.—p. 225.
*Symptoms from Apex of Lung. A. Campani and F. Bergolli.—p. 230.
Recent Literature on Gastric and Duodenal Ulcer. E. Aievoli.—p. 231.

Semeiology of the Apex.—Campani and Bergolli say that in the early phases of disease of the lungs a loss of elasticity in the region of the apex may be the only sign that anything is wrong. This can be detected by the lack of expansion of the lung at the apex when the subject sits up in bed, after long horizontal reclining. Auscultation shows that the respiration sounds at the apex on the suspected side are scarcely if at all audible. Gradually, in the course of about two minutes, the respiration sounds at the apex become audible, but they are not symmetrical at first. Gradually, however, the difference between the respiration sounds grows less and less, and they become symmetrical. This temporary asymmetry in the breathing sounds during the transition from the horizontal to the sitting positions seems to be an instructive sign of incipient pulmonary tuberculosis. Comparison of the pulmonary breathing sounds with the tracheal breathing sounds is also instructive for delimitation of the apex. The point where the apex murmur is first heard, in ausculting from the neck slanting downward, is marked on the skin. This point is lower the more pathologic the apex, as a rule, although with diffuse processes the faintness of the respiration is more instructive as the outlines of the apex are less distinct.

*Disturbances from Displacement of Uterus. E. Aievoli.—p. 262.

General Disturbances from Displacement of the Uterus.—Aievoli discusses the symptoms which can be traced to displacement of the uterus, saying that considerable skepticism is unavoidable with extragenital symptoms. Neuropathies ascribed to backward displacement can generally be explained by an unstable nervous and mental state; this depends more on infantilism than on the static anomalies in the genital sphere. But metrorrhagia and abnormal menstruation are liable, from the interference with the circulation of blood and lymph which is inevitable with retrodeviation plus flexion, and the abnormal bacteriologic conditions likely to result. Retrodeviation may exist without these, and there may be no signs of stasis and congestion even with retrodeviation and the above conditions. The danger of retrodeviation for pregnancy often turns the scale in favor of intervention in dubious cases.

*Local Epidemic of Goiter. P. Rondoni and A. Bellini.—p. 121. Conc'n.

March 22, 1919, **20**, No. 12

Simplification of Kjeldahl Test for Nitrogen. E. Pittarelli.—p. 133.

Epidemic of Goiter.—Rondoni and Bellini relate that goiter suddenly appeared in a district near Florence where its endemic presence had not been previously known. Eleven of those affected were given ten drops of tincture of iodin daily, and three were treated with salol and benzonaphthol, each 2 gm. per day and later with 1 gm. of thymol. This intestinal sterilization did not show any effect on the goiter, while in all those taking these small doses of iodin the goiter retrogressed, and in some completely disappeared. No factors could be discovered which could be regarded as responsible for the novel epidemic, unless possibly the weather in this season might have checked the growth of certain plants which normally supply iodin to the air or to the food. But this does not explain why the twenty cases were restricted to one small district.

Brazil-Medico, Rio de Janeiro

*Roentgen Finger Prints. J. A. G. Fróes.—p. 73.
*The Microbe of Venereal Granuloma. H. de B. Aragão.—p. 74.
*Gastroptosis. O. Clark.—p. 77.

Finger Roentgenograms for Identification Purposes.—Fróes regards as important progress in anthropometric identification, Béclère's recent endorsement of "anthropometric radiography of the thumb" as a further form of identifying records. Fróes suggests, however, that it would be better to include the outline of the nail, and not to restrict the records to the thumb. This *roentgendactyloscopia onychographica,* with the outline of the finger nail and of the terminal phalanx, adds thus two new important and specific elements to the record.

The Microbe of Venereal Granuloma.—Aragão states that the encapsulated bacillus, which he, with Vianna, found as the characteristic germ of venereal granuloma, is the same as Donovan's bodies. As its morphology and mode of scission differ from those of other microbes, they regard it as a new species and in their publications on the subject in 1912 they named it the *Kalimmato bacterium granulomatis.* He reports now that their further research has confirmed their statements on its mode of reproduction, its reactions and parasitism.

Gastroptosis.—Clark remarks that the surgeons in Brazil are living in a vicious circle; they have a high death rate because they do not see patients with chronic abdominal affections until they are in an advanced stage of the disease, and, on account of the high death rate, they do not get the patients in time for successful operations. In the United States, he adds, the surgeons live in another sphere, with fine statistics on account of early operations, and a chance for early operations on account of the low death rate. Brazil has great surgeons, he reiterates, but they can operate only for complications, seldom for the primary affection. He describes three cases of gastroptosis which represent the three schools of opinion on gastroptosis. One was a case of asthenic dyspepsia requiring merely the Weir Mitchell treatment for complete subsidence of all the previous distressing disturbances. In the second case severe symptoms for three or four years, gastralgia and gastroptosis with extreme dilatation and retention, and finally melena were ascribed to a duodenal ulcer. The laparotomy showed the veins in the stomach very turgid but otherwise the stomach and the duodenum were apparently sound, and after gastropexy all disturbances subsided at once and permanently. These two cases show that both Stiller and Rovsing are correct in their assumptions in certain cases, and that one single law cannot apply to all. In a third case, symptoms from the stomach indicated gastric ulcer accompanying gastroptosis, without the least tenderness at McBurney's point, but the laparotomy revealed the upper digestive tract sound, except for the gastroptosis, while the appendix was found chronically diseased. Complete cure followed gastropexy plus appendicectomy.

Identity of Cuchipe and Yaws. J. F. Martínez.—p. 45.
Pathologic Anatomy of the Lymphatic Gland. O. Hercelles.—p. 52.

Gastroduodenal Ulcers.—Odriozola emphasizes the necessity for the physician to be calm and reassuring when summoned to a patient with hemorrhage from the bowel and other signs of gastro-intestinal ulceration. These hemorrhages scarcely ever prove fatal, and are arrested usually by enemas of hot water (45 C. or 113 F.) with 0.01 gm. opium every two hours, or an injection of morphin to relieve the pain which usually preceded the hemorrhage and persists. He protests against saline enemas or infusion as the salt tends to increase the secretion of gastric juice. Thirst is combated by moistening the lips with glycerin and giving a little ice to suck or lemon juice.

*Nerve Elements in Auriculoventricular Bundle. P. M. Barlaro.—p. 277.
*Nationality and Dementia Praecox. F. Gorriti.—p. 282.

Nerve Elements in the Auriculo-Ventricular Bundle.—Barlaro gives twelve illustrations of the heart and the microscopic findings in the auriculo-ventricular bundle, and protests that too much importance is assigned to the bundle of His and not enough to the intracardiac nervous system. He theorizes to explain the birth of the auto-impulse, ascribing it to the system of minute nerve ganglia seen in the microscopic sections of the bundle of His in cattle.

Nationality and Dementia Praecox.—Gorriti states that among 1,410 cases of dementia praecox at the National Insane Asylum of Argentina, twenty-six nationalities are represented. Foreign nationalities form over 50 per cent. of the total although their population is so small compared with the Argentine population. The principal contingents are Spanish, 279 to a population of 512,742; Russian, 32 to 54,956 and Italian 275 to 587,497. Many of the dements born in Argentina have foreign parents. Consequently immigration is an important factor in mental disease in countries with much immigration. He comments that the persons that take the step of emigrating are usually more adventurous and unstable members of a community, easily influenced by the example of others' emigrating, and liable to suffer from the change in customs and habits, the disappointments and hardships of the new life, especially in the cities.

*Encysted Peritonitis in Upper Abdomen. R. Franco F.—p. 284.
*Pyelitis *in* Children in Bogotá. J. Bejarano.—p. 293.
Indications and Technic for Venesection. R. Sanmartin L.—p. 302.

Encysted Peritonitis.—Franco evacuated a collection of pus in the cavity formed by the greater and the lesser omentum and the posterior aspect of the stomach. It had formed a round, almost fluctuating mass, filling nearly the whole of the upper half of the abdominal cavity, with dulness except where the stomach had been pushed up. Both the purulent pleurisy and the encysted peritonitis were the work of the pneumococcus, and had been preceded not long before by influenza. The best mode of access was through the gastrocolic omentum.

Pyelitis in Children in Bogotá.—Bejarana says that in no other pathologic entity is there so much vagueness and imprecision as in pyelitis in children. It is often masked by the primary disease responsible for it, especially gastrointestinal disease in young children. Polyuria, particularly at night, and a milky appearance of the urine are the most suggestive manifestations, aside from the pyuria. The mothers—"those great empiric clinicians"—tell the physician that the child "wets a little more than usual in the night." Pain in the costovertebral angle and at Bazy's point is a useful sign when present, suggesting involvement of the ureter. A tendency to edema of the legs was always evident in his cases, even on a salt-free diet. He comments on the great frequency of pyelitis in children at Bogotá; it is liable to follow typhoid, influenza, pneumonia and enteritis. Possibly the climate has something to do with its prevalence there. In all his cases and those he has heard of from others, the children were all girls, the age from 6 months to 7 years. The pyelitis seems to take a long time to heal at Bogotá, ten or more months elapsing—at least in his cases—before he could affirm a definite cure. After the acute phase was past, in one case the pyelitis seemed to slumber for two months and then the symptoms all returned without appreciable cause. In all the cases of this kind, the primary disease had been intestinal infection. One child of 15 months still has this recurring pyelitis which first developed at 6 months. None of his cases have terminated fatally. He has found potassium citrate effectual in transforming the reaction of the urine to alkaline, the fever subsiding and diuresis becoming profuse under it. When a purgative is given, this diverts water away from the kidneys, and the symptoms of pyelitis flare up again. There is no specific remedy, and treatment can be only tentative.

Revista Clinica, Medellín

June, 1918, **3**, No. 9

*Appendicectomy in Colombia. A. Castro.—p. 394.
*Slow Endocarditis. *L. Posada Berrio.—p.* 430.
Suppurating Phlebitis after Hysterectomy for Incipient Cancer of Cervix. A. R. Moreno.—p. 437.

Appendicectomy in Colombia.—Castro refers merely to the state of Antioquia, in Colombia. He reviews 228 appendicectomy operations that have been done there up to November, 1917. The appendicitis was traced to gonorrhea in a large number of cases in women, and appendicitis seemed to occur frequently in the pregnant. The appendix was often involved in right tubal pregnancy.

Slow Endocarditis.—Berrio comments on the constant stereotype picture presented by this disease, and yet its comparative rarity causes the symptoms to be frequently ascribed to everything but the right cause. There is almost invariably a history of acute articular rheumatism in the past, and some recent tonsillitis or other acute infection. Purpura never fails to develop at some stage of the process, and joint disturbances, enlargement of the spleen and the heart lesions are explained by the streptococcus in the blood. A case recently encountered presented also the typical painful red nodules in the fingers which some regard as pathognomonic. The pulpa of the fingers or toes is a frequent site of nodules. They may suggest an incipient felon. Painful red patches may be found on the limbs or trunk. Death occurs in from four to twelve months.

*Dyspnea in Relation to Abdominal Cancer. Braulio Mejia.—p. 511.
Gangrene of the *Extremities.* Gil J. Gil.—p. 554.
Present Status of Our Knowledge of the Thyroid Bodies. A. Castro. —*p. 560.*

Dyspnea with Abdominal Cancer.—Mejia has noticed sudden difficulty in breathing as a prominent symptom with abdominal cancer, and is convinced that there is a causal connection between them. Sudden, unexpected dyspnea coming on without apparent cause in an elderly person has often proved the first appreciable warning of an abdominal cancer. In one case the dyspnea appeared suddenly during the night in a women of 68 without pathologic antecedents. The suspicion of gastric cancer was confirmed by the course of the case, the woman dying in six weeks with symptoms suggesting acute dilatation of the heart. In another case a man of 70, known to have long had a perfectly compensated valvular lesion and living a most hygienic life, suddenly developed dyspnea. Failing compensation was assumed until palpation revealed a tumor in the liver, already inoperable. Loss of appetite and weight during the last two months had not been heeded until the sudden attack of suffocation. Mejia ascribes the dyspnea to some toxic action on the centers in the medulla, and warns that a sudden attack of suffocation, without known cause, in the elderly, should always suggest the possibility of abdominal cancer.

Relations Between Obsessions and Manic-Depressive Psychoses. R. A. G. Salazar.—p. 60.
**Treatment of Infections in General.* A. Arteaga.—p. 66.*

Treatment of Infections in General.—Arteaga declares that we cannot rely on vaccination to protect us against all infections as the results are uncertain in some and dangerous in others. But we can all guard against disseminating and contracting infection. The hands, the mouth and the nasal passages of patient and attendants can be repeatedly cleansed and disinfected. Hygiene rather than pharmacology is needed, stimulating the kidney and skin functioning and exaggerating the intestinal. He advises to refrain from all food during the first twenty-four or forty-eight hours, but sweetened lemonade should be given freely to act on the kidneys. The infection may be called an acute microbian anaphylaxis, and it should be treated along the same lines as any anaphylaxis, warding off exogenous toxins and promoting the elimination of the endogenous. He warns that fever alone, without unconsciousness or "limping" of the heart, does not require special treatment. Fever in itself is not dangerous, as is evidenced by the absence of delirium, stupor and convulsions in children with temperature running up suddenly to 104 F. He warns further against abuse of cool baths. He does not give them in typhoid, merely keeping the skin cool and clean, and has never had cause to regret it.

Treatment with Thallium Acetate of Parasitic Disease of the Scalp.—Cicero lauds roentgen treatment as superior to all other methods in treatment of ringworm, etc., as time and experience have confirmed Sabouraud's pioneer work in this line. But, as Cicero remarks, roentgen treatment is not always available, while excellent results can be obtained with thallium acetate which Sabouraud had been recommending before he turned to roentgen treatment. Cicero now has a record of 354 cases of alopecia treated with thallium acetate. It was effectual in causing the dropping out of the diseased hairs, after which the hair grew again apparently normal. He gave it internally, as a rule, in a 5 per cent. aqueous solution; two drops of this are equivalent to 0.005 gm. of thallium acetate, and he gives as many drops as is represented by twice the number of kilograms of the child's weight. The smallest dose given was 0.07 gm. to a girl that weighed 14 kg. and the largest, 0.195, to a woman that weighed 39 kg. No untoward by-effects were observed, while the hair grew in again afterward. The lashes and eyebrows did not drop out, as also the hair that had grown again after roentgen depilation. The hairs did not drop out after taking the thallium until an interval of two weeks had elapsed. The only by-effect was occasional profuse salivation.

*Indications for Operation with Bilateral Ureter and Kidney Lithiasis. J. A. Presno y Bastiony.—p. 93.
Factitious Conjunctivitis. F. M. Fernández.—p. 100.

Intestinal Delineator.—This article was the substance of an address by Einhorn at a meeting of the Academia de Ciencias Medicas, at Havana. It is accompanied by fourteen roentgenograms showing the delineator at different points on its way through the bowel.

Bilateral Ureterorenal Lithiasis.—Presno discusses the indications with bilateral lithiasis, and reports the case of a woman of twenty-six who had had kidney colics at times since the age of 14. She had borne four healthy children. In 1917, nephrostomy was done on the right kidney. She was free from pain for forty-one days, Then the pain returned and has persisted since. She never had pain in the left kidney but the roentgen rays showed a large calculus in the pelvis of the left kidney although it had never made its presence felt and would have escaped detection except for the roentgenoscopy. The operation included extraperitoneal ureterolithotomy on the right ureter, followed by pyelotomy and pyelostomy for the silent calculus in the left kidney. The pains and disturbance in the right kidney proved to be merely reflex phenomena from the stone impacted in the ureter.

Insufflation of Iodoform Effectual Treatment of Nasal Myiasis. A. Iarcho.—p. 175.

Topical Treatment of Pleurisy Without Effusion.—Cetrángolo reports several cases of pleurisy in which he applied the technic for making an artificial pneumothorax, thus injecting air directly into the focus of the disease. By insufflating 100 c.c. of air in cases of plastic pleurisy, the pain and friction sounds subside, the distention stretching the adhesions. The pain is increased the first day, but then usually disappears completely. From one to three insufflations are made at weekly intervals, with progressive improvement. In some cases the air was medicated, that is, it was passed through cotton moistened with 2 per cent. camphorated oil. One insufflation of 100 c.c. of the camphorated air cured one man with severe pains in the shoulder, worse during repose and at night. The pain increased after the insufflation, but by the next day had vanished permanently. One man with tuberculous lesions in both lungs and intense pain in the right side was insufflated with 120 c.c. of air. The pains grew worse for two days and then vanished completely. Cetrángolo thinks that he is the first to apply topical medication to suspicious pleurisies with the artificial pneumothorax technic.

Convulsions After Taking Anise Tea.—Tonina gives the details of the cases mentioned in the Buenos Aires letter, p. 1309, in which children developed convulsions after drinking tea made from anise. The drug proved to be a poisonous kind of anise. The convulsions were accompanied by acute dilatation of the stomach, an actual ileus, with cyanosis.

Excessive Salivation as Sign of Uremia.—Giacobini calls attention to the intense salivary secretion which he has found accompanying uremic phenomena, rising and falling with them. In the graver cases there may be a sensation of the taste of urine in the mouth, changing to a salty taste as the uremia grows less intense. Some patients assert that milk tastes salty to them. There is also a tendency to fever at times with uremia, and hiccup.

*Thyroid Sterility. G. Giacobini.—p. 272.
*Ampules with Visible Index of Sterilization. S. Cambronero.—p. 277.

Fracture of Clavicle.—Gutiérrez describes the various methods for treating fracture of the clavicle, and reports the details of twelve cases in which he applied Lejars' figure-8 plaster bandage, with eminently satisfactory results.

Morphin and Cocain in Putrefied Tissues.—Palet relates that morphin resists putrefaction well, as he was able to determine its presence in the putrefied tissues after seven months in a case of chronic addiction to morphin, and after two years and a half in a case of acute poisoning. Cocain (or products of its transformation) was found in the tissues seven months after death. The red tint assumed by the viscera when treated with Dragendorff's sulphuric acid method is a reliable sign of the presence of morphin.

Thyroid Sterility.—Giacobini has demonstrated the existence of sterility from ovarian insufficiency, and he now presents evidence to the effect that thyroid insufficiency may also be responsible for sterility. In the first of two typical cases, the woman, after bearing a healthy child developed constant headache and metrorrhagias, indicating thyroid insufficiency, and there was no further conception. In the second case the woman presented evidences of thyroid insufficiency and had never conceived during her eight years of married life. Under thyroid treatment their symptoms promptly subsided, and both women became pregnant soon after.

Index for Sterilization of Ampules.—Cambronero suggests that each ampule for intravenous use should have in the fluid inside a small glass tube containing some substance which does not melt until a given, very high temperature is reached. Then, if a scrap of some solid dye is incorporated in this solid substance we have an index which will show if the contents of the ampule have been properly sterilized. When the sterilizing temperature is reached, the solid in the glass tube will melt; this will dissolve the scrap of dyestuff, and the whole contents of the little tube will be stained throughout in their melted fluid condition. As they solidify again, the diffuse tint guarantees that at least the actually sterilizing temperature for the ampule has been attained.

*Direct Method for Platelet Count in the Blood. O. Thomsen.—p. 161.
Magnesium Sulphate in Tetanus. J. Nordentoft.—p. 169.

Direct Blood Platelet Count.—Thomsen comments on the unreliability of the usual methods in vogue for determining the blood platelet count, and describes a method which seems to be quite accurate. He found with it a blood platelet content of from 206,700 to 413,400 in healthy persons, the average being below 300,000. He examined sixty-eight persons, sick and well, including some with infectious diseases. In the latter the platelet count was high. His method consists in preventing coagulation in the blood by adding a little sodium citrate, then setting aside until the corpuscles have settled to the bottom, and then counting the blood platelets in the citrated plasma above. The platelets do not settle down until after several hours, while the corpuscles settle not only by their own weight but by the influence of agglutination of which there is always more or less in different specimens of blood. He gives formulas and tables to facilitate the computations.

*Deforming Spondylitis in Relation to Sciatica. H. I. Schou.—p. 365.

Spondylitis Deformans and Sciatica.—Schou reports 15 cases of neuralgia in the legs in which there were evidences of deforming spondylitis, most pronounced in the lumbar portion of the spine. Twelve of the patients were men from 50 to 81 years old, with one man of 37 and one of 40. They were classed as cases of sciatica, but the pains were localized in the domain of the femoral nerve, and increased during exercise. In 2 of the men the pains were bilateral. There was tenderness over the sciatic nerve in most of them, but in 2 there were no tender points to be found, although the pains were severe; in one case there was tenderness in the lumbar musculature. The pains started in the lumbar region, and there were frequent periods of remission.

Points like these, in which the neuralgia differs from ordinary sciatica, call for roentgen examination of the spine in such cases. The evidences of the spondylitis were most marked in the lumbar region, that is, near the lumbar plexus and where the upper roots of the sciatic nerve emerge from the spinal canal. Reexamination a few months to four years later showed that 5 of the 12 patients had quite recovered, 5 still had pain when exercising, and 2 of the patients were still incapacitated by their affection. The exostoses with deforming spondylitis may merely impede the circulation and thus induce the neuralgia without direct compression of the nerve, or the nerve root may degenerate under the influence of compression and the neuralgia finally disappear. In a further series of 3 cases, roentgen examination showed a single large exostosis on the spine or sacrum, in men or women between 54 and 56, with symptoms of sciatica on the same side as the exostosis.

*Necropsy after Reduction of Hip Joint Luxation. H. Scheuermann.—p. 393.
*Semicentennial of First Publication on Adenoid Vegetations. E. Schmiegelow.—p. 398.

Necropsy Findings in Hip Joint After Bloodless Reduction.—Scheuermann gives the roentgen and necropsy findings in the case of a little girl, not quite 4, who died from pneumonia nine months after correction of congenital dislocation of both hip joints. The conditions approximated normal almost completely. The upper capsule pocket in which the head had previously rested had shriveled and shrunk until not a trace of it remained. Among the lessons taught by this case is the imperative necessity for solid fixation with plaster after reduction, as the upper margin of the deformed acetabulum is weak, and the retention of the head in its socket is due almost exclusively to the shriveling of the capsule pocket and the development of the glenoid ligament, both of which occurred faultlessly in this case. The cast must include the trochanter, and the correct position of the head should be verified with roentgen examination after a month. He adds that in every case it is important to place the femur from the very first in right-angled abduction and outward rotation. This is the only way to ensure the development of the glenoid ligament and the shriveling of the capsule which are indispensable to successful retention of the head.

Semicentennial of First Report on Adenoid Vegetations.—Schmiegelow's address was delivered at a special meeting of the Danish Otolaryngologic Society in honor of the semicentennial of H. W. Meyer's pioneer publication on adenoid vegetations. He discusses the importance of these vegetations for otology and medicine in general, and recalls that Meyer's first communication on the subject appeared in this same journal, the *Hospitalstidende*, Nov. 4, 1868. Meyer died in 1895, nearly 71 years old, after seeing his assertions in regard to adenoid vegetations confirmed the world around.

THE ETIOLOGY AND TREATMENT OF THE DIARRHEAL DISEASES OF INFANCY

LEWIS WEBB HILL, M.D.
BOSTON

The prevention of infant mortality is one of the most important medical questions of the day. More babies die every year from diarrheal diseases than from any other one cause. These diseases are largely preventable, and in most cases respond to proper treatment, whereas many improperly treated patients die. It is, therefore, essential in any affort to reduce infant mortality that all physicians dealing with children should have as clear an idea as possible of these conditions.

Any diarrhea is caused by increased intestinal peristalsis. This increased peristalsis is caused by some irritant acting on the intestinal mucous membrane, and it is best to classify diarrheal conditions according to the type of irritant that is causing the trouble. Broadly speaking, according to this method of classification the diarrheal diseases of infancy may be divided into three groups: (1) mechanical diarrhea, due to mechanical irritation; (2) fermentative diarrhea, due to chemical irritation, and (3) infectious diarrhea, due to bacterial irritation.

In the first group, the irritation is mechanical and is caused by undigested pieces of food or by such things as fruit skins or seeds.

In the second group the trouble is caused by irritating products from fermentation or putrefaction of food in the intestine, brought about in several different ways, as we shall see later. There is no infection by bacteria of the intestinal mucous membrane in this condition; it is the intestinal contents which are infected.

In the third group there is actual invasion of the intestinal mucosa by bacteria, with catarrhal inflammation, or often actual ulceration. It is of great practical importance to bear in mind these distinctions, as the feeding for the different sorts of diarrhea may be entirely different; what is proper for an infectious case might be fatal in a fermentative case. I cannot emphasize too strongly that not all infantile diarrheas are the same, and that they should not all be treated in the same routine manner. The first essential is a correct diagnosis, and in order to arrive at this the etiology of the three groups must be thoroughly understood.

I. MECHANICAL DIARRHEA

This type of diarrhea is fairly common, and is more likely to be seen in children above the age of 1 year than in those younger. It is caused by mechanical irritation of the delicate intestinal mucosa from such things as grape skins, cucumbers and raw fruit. It is a common practice among many ignorant people to feed all sorts of indigestible foods, particularly raw fruit, to small children from 1 to 5 years of age, long before they are ready for it. Some children seem to be able to stand it, but the majority cannot, and no raw fruits should be fed to any child under 5 years old. In many cases the mechanical irritation of the intestine paves the way for organisms to attack it in the irritated places so that often a mechanical diarrhea may change to one of the true infectious type. A typical case of mechanical diarrhea would run about as follows: A child of 2 is given a peach to eat, skin and all. The peach may be ripe, or it may not be. Soon after, the child is taken severely sick with vomiting and diarrhea. The stools are usually five or six in the twenty-four hours, and are likely to contain undigested peach pulp and skin. The vomiting may be so severe as to be uncontrollable, and it is in this type of diarrhea that gastric disturbance is most common. In some cases there may be a tremendous amount of toxemia, and not infrequently these children die, partly, I believe, from acidosis caused by the severe vomiting, and partly probably from the absorption into the circulation through the injured intestinal wall of toxic material or possibly bacteria from the intestine. Every practitioner of experience has seen cases such as this. Last summer I saw a boy of 6 at the Children's Hospital who died in forty-eight hours from eating a raw cucumber. In ordinary cases the child will be well in two or three days, and the diagnosis and treatment offer no difficulty save in those cases which develop infectious diarrhea.

The treatment consists simply in purging the child with casor oil or calomel, putting him to bed, giving him barley water or some other gruel for twelve hours, with plenty of water, and then starting him on a bland, nonirriating diet of cereal and boiled skim milk. This is the simplest and least important of the infantile diarrheas.

II. FERMENTATIVE DIARRHEA

This is a more complicated and important condition, and is the most common diarrhea of babies. It is most likely to occur in children under 1 year, but may be seen at any age. It is brought about by abnormal decomposition of food in the intestine, caused either by the bacteria which are already there or by bacteria introduced from without. The products of fermentation irritate the intestinal mucosa and cause a diarrhea, but the mucous membrane is not attacked by bacteria. The abnormal decomposition is usually that of sugar, and may be caused in several ways. In order for sugar fermentation to occur two conditions must exist: unabsorbed sugar in the intestine, and bacteria in the same portion of the intestine to attack it. Under normal conditions the small intestine is relatively sterile, the large intestine is swarming with bacteria. Therefore, any conditions that allow a considerable amount of undigested sugar to proceed lower than is normal in the digestive tract, or which will allow bacteria to flourish in the small intestine, where there is always unabsorbed sugar, will bring about sugar fermentation. Let us consider some of these conditions.

1. *Overfeeding with Sugar.*—If too high a percentage of sugar, or if too much food, thus giving a large amount of sugar, is fed to a baby, all of the sugar cannot be absorbed. What is not absorbed passes into the lower part of the intestine and the ever-ready bacteria there attack it and ferment it.

2. *"Parenteral" Infections.*—It is well known by every practitioner that babies suffering from such affections as rhinitis, bronchitis or otitis media are likely to have loose, greenish stools. The probable reason for this is that in these conditions the digestive juices are reduced in amount, so that sugar is not digested so well as normally, and thus is fermented; or that under the general debilitating influence of any extra intestinal disease the intestinal mucous membrane loses some of its antibacterial power and thus allows bacteria to flourish higher in the intestine than they would normally.

3. *Overheating.*—Overheating of the body is an important cause of sugar fermentation. This is well known clinically and has also been proved by animal experimentation. The practice of dressing babies too warm in hot weather is undoubtedly the cause of a good many cases of sugar diarrhea. The explanation of this is probably very similar to that for "parenteral" diarrhea. Owing to the debilitating heat the digestive juices are lessened in amount, and the efficiency of the mucous membrane is impaired in such a way that undigested sugar is permitted to pass down where bacteria can get at it, or the bacteria are allowed to come up and flourish where the sugar is.

4. *Nervous Exhaustion and Excitement.*—These may bring about sugar fermentation, probably in a way similar to that in which it is brought about in the last two conditions I have discussed. However, it is not a particularly frequent or important cause of sugar fermentation.

5. *Constitutional Weakness.*—There are certain babies who, on account of constitutional weakness, never seem to be able to take much sugar, or indeed much food of any sort, without diarrhea. It is probable that their digestive juices are inefficient, and that there is always a great deal more bacterial growth in the small intestine than there should be.

The types of sugar fermentation enumerated above are all brought about by the normal intestinal bacteria's taking advantage of the abnormal conditions of the host. The next and by far the most important type of sugar fermentation is caused by abnormal bacteria introduced from without in bad milk. Bad milk is, I believe, the most potent source of sugar fermentation that there is, and gives rise to the most severe cases of diarrhea. There is probably no specific organism that accomplishes this, although investigators have tried at various times to look on the condition as a specific infection. A great many different sorts of bacteria, when introduced into the small intestine, may bring it about, and probably two of the most common offenders are the *Bacillus aerogenes-capsulatus* (gas bacillus) and the colon bacillus.

The foregoing will serve to show the main causes of sugar fermentation; let us now see what chemical processes are involved. When sugar is fermented by bacteria, acids are formed. These may be divided into two groups: the volatile acids, such as formic, acetic and butyric, and the nonvolatile acids, such as lactic. The volatile acids, particularly, are formed in large amounts, and are the ones which do the most harm. The nonvolatile acids are relatively harmless. It is surprising to see how much free acetic acid may be recovered from the stools of some babies with sugar fermentation, and when one takes into account its extremely irritating nature it is easy to see how much damage may be done. The volatile acids cause harm (1) by increasing peristalsis and causing a diarrhea by irritating the intestinal mucosa; (2) by injuring the mucosa in such a way that its antibacterial function is impaired, or to such an extent as to allow toxic material from the intestine to pass through into the general circulation, a thing which would never happen normally; (3) by drawing on alkali reserve of the body in an attempt to neutralize the excessive acidity, thus probably helping to cause an acidosis; and (4) by upsetting the normal chemical processes of digestion, most of which cannot go on satisfactorily in an excessively acid intestine.

DEGREES OF SUGAR FERMENTATION

In a rough way, sugar fermentation may occur in three degrees of severity, which vary a good deal in their chemical conditions and clinical appearance.

1. The condition may be of a very mild type, in which a normal baby has two or three very acid stools a day of a consistency rather looser than normal. These stools may be of the normal color, or slightly greenish, with usually only a little mucus. The baby is not sick, the condition is a very mild one and almost always clears up readily with proper treatment. Its importance lies in the fact that untreated, the condition may become severe, and may ultimately lead to most serious results. This may be seen at any time of year, and probably has nothing to do with bad milk.

2. It may be a more severe condition, usually seen in the summer during a "muggy spell," but may occur at any time. The baby will have from five to ten very loose stools a day, containing a good deal of mucus, and many small soft curds of undigested milk. He is fussy and irritable, but is not very sick in most cases. His buttocks are likely to be red and excoriated from the excess of acid in his stools. The temperature is usually from 99.5 to 101. In this section of the country, at any rate, I believe this type of diarrhea is caused more often by bad milk than in any other way. In other sections where all milk fed to babies is boiled as a routine, it may be more often caused by some of the other agencies already enumerated. The condition is a local intestinal one; the intestine has been irritated, the processes of digestion have been disturbed, but the baby's body chemistry as a whole has not been upset. The process has as yet caused no trouble further than in its original locus, the intestine. If the patient is properly treated, the disease should be arrested without difficulty; improperly treated or neglected, the baby may pass over into the state which I shall call Type 3, a much more serious condition ("alimentary intoxication").

3. In this case the baby is very sick. He usually has a high temperature, but in certain cases he may be so prostrated that the temperature is subnormal. The fontanel, abdomen and eyes are sunken, the skin hangs loosely on the flesh, and has lost its elasticity—all from a loss of water. There is a profuse watery diarrhea, ten to twenty stools in the twenty-four hours. The baby takes no interest in his surroundings, his mentality is very dull, and he may be roused with difficulty. The breathing is deep and sighing (hyperpnea), and the urine may show sugar and casts. This is the picture of "alimentary intoxication," and a most precarious and serious condition it is. Here the process originally starting as a local intestinal condition has progressed so that it has changed the general metabolism, and has perverted the chemistry of the entire body. There is a negative nitrogen and salt balance, there is loss of a large amount of fluid, very often severe acidosis, and last, but not least, it is probable that many injurious substances from the intestine are absorbed into the general circulation through the injured intestinal mucosa, thus adding to the severity of the condition.

I. TREATMENT IN VERY MILD CASES

Many normal babies are likely to have periods of mild sugar fermentation occasionally. In nearly all the following simple treatment will clear the condition up, often in twenty-four hours, and will prevent the development of a severe sugar fermentation. A purge is not necessary unless the baby has fever, and this is uncommon. All sugar should be omitted from the milk modification, and the solution boiled for three minutes. One teaspoonful of compound chalk mixture should be added to each bottle. Usually after twelve or twenty-four hours of this feeding the stools will return to normal, when sugar can be added gradually, and in two or three days the baby will be back on his regular modification.

II. TREATMENT IN THE MORE SEVERE CASES

Groups 2 and 3 may be considered together in the discussion of treatment.

1. *Purgation.*—It is a mistake to give a purge as a routine in every diarrheal disease. If there is any harmful material in the intestine which is not coming out as fast as it should, a purge ought to be given—otherwise not. It is not rational to purge a baby who is already having a great many loose stools a day and whose intestine is emptying itself of toxic material as fast as it possibly can. In such cases castor oil or calomel adds insult to injury. On the other hand, a baby who is seen at the onset, who has fever, and who has not as yet been emptied by diarrhea ought to be purged at once, and it is often striking to see how the temperature will drop and how much more comfortable the baby will be after a good cleaning out.

2. *Feeding.*—This is the most important part of the treatment, and it is in this that mistakes are most frequently made. After the initial purge the baby should be deprived of food for about twelve hours, being offered nothing but weak barley water. Many babies will take this readily when they will not take plain water. The object of the starvation is to empty the intestine as completely as possible and to discourage the further increase of bacteria by offering them no food on which to grow. The principles of feeding are the same in every severe case of sugar fermentation; the details may have to be modified according to circumstances.

The condition we are dealing with is caused by an excess of acid in the intestine from the fermentation of sugar by some organism or group of organisms which thrive on sugar. Such organisms are likely to be greatly diminished or to die out if their principal food supply is withdrawn. Therefore, the great principle in treatment is to offer a food which contains very little sugar, and a considerable amount of protein, for as a rule the organisms that thrive on sugar do not thrive on protein. Such a food can be prepared in a number of ways, depending largely on the resources of the people one is dealing with.

a. Albumin Milk.—This, or a modification of it, is the ideal food, and babies with sugar fermentation do better on it, I believe, than on any other. It is too difficult of preparation to be used among the ignorant, but an intelligent mother can make it satisfactorily. There have been numerous modifications of albumin milk, but the original preparation is probably as satisfactory as any. It is made by rubbing the curds from a quart of milk (prepared with essence of pepsin) through a fine sieve several times until they are in a finely divided condition. These curds are then mixed with a pint of buttermilk diluted with a pint of water. The resulting mixture contains fat 2.5 per cent., sugar 1.5 per cent., protein 3.5 per cent. Such a mixture as this offers practically no sugar for the sugar-splitting bacteria to grow on, and on account of its high protein content, it tends to make an alkaline intestine; in an alkaline intestine calcium soaps tend to be formed, which favor the formation of pasty, semi solid stools. The albumin milk should be fed in very small doses at first—perhaps one fourth as much albumin milk as the usual amount of milk the baby would take, with the balance made up of water. If it is borne well, the amount may be rapidly increased. As the baby improves and as the bowel discharges become less frequent, small amounts of sugar may be gradually added. The best sugar to use is some maltose-dextrin preparation, as it ferments less readily than lactose does. Albumin milk is only a temporary food and should not be continued longer than a few weeks.

In a large city where there is a milk laboratory it is usually simpler to have the milk prepared at the laboratory from cream, water and precipitated casein, as any amount of casein or of fat desired can be obtained in this way, thus better suiting the preparation to the digestion of the individual baby than when a stock formula is used.

b. Skim-Milk with Powdered Casein.—Another satisfactory feeding is with simple dilutions of skim-milk to which powdered casein has been added. There was until a year or two ago a product on the market which was a semisoluble calcium caseinate. It could be very readily mixed with skim-milk and water to form a gruel, and in this way it was possible to secure very low sugar percentages in combination with a high protein. In the summer of 1915 I fed a good many outpatients by this method, and got very good results, fully as good, I believe, as could have been obtained with the more complicated albumin milk. The chief advantage of the powdered casein method is its extreme simplicity. Since the war this preparation has been unobtainable, and, so far as I know, no other has been put on the market to take its place. There is an urgent need for such a preparation, and it is a pity to see so many worthless proprietary foods on the market when powdered casein, which is really of great use, could be made so easily by almost any one of the proprietary food companies.

c. Lactic Acid Milk.—In some cases lactic acid milk or buttermilk feeding may be of value, the idea being that the lactic acid organisms of the buttermilk flourish in the intestine and supplant the organisms that are doing the damage. Buttermilk, also, is not very rich in sugar and contains a good deal of protein in an easily assimilable form. Unless fresh buttermilk can be obtained, it is best prepared at home, from skim-milk and cultures or tablets containing the lactic acid or Bulgarian bacillus. If it is desired to use the lactic acid principle, that is, flooding the intestine with lactic acid bacilli, it is a great deal better to use a lactic acid milk, than tablets or vials of the culture, as infinitely more bacteria can be given in the first way than in the second. It is worth while, however, if the baby will not take sour milk, to try the liquid cultures or the tablets. This plan of feeding is used a great deal. Some experienced pediatricians use the butter-milk principle constantly, some consider it of no value. As far as I know, there is no very good evidence one way or the other; some patients it helps, some it helps not at all, and it is time some one did some experimental work on the subject, for what little we really know about it has been handed down from the days of Metschnikoff, who first elaborated the idea.

d. Skim-Milk Dilutions.—The way most of us in the outpatient department of the Children's Hospital treat sugar fermentation is with skim-milk dilutions, usually beginning with a third or a half skim-milk, the rest barley water or water, and gradually increasing as the stools become better. By this method improvement is not so rapid as it is with albumin milk, but in most of the outpatient class of patients or with the ignorant part of one's private practice, complicated methods of feeding cannot be used, and simplicity is of paramount importance.

MEDICINAL AND OTHER TREATMENT

Colonic Irrigations.—If seen at the onset a high colonic irrigation with physiologic sodium chlorid solution may do a great deal of good by helping to empty the intestine. Later in the course of the disease, it does less good, and indeed is likely to do more harm than good by irritating and disturbing the child.

Water.—Next to the feeding, the free administration of water is of the greatest importance. The baby is losing a large amount of fluid from the body in the watery discharges, and it is vital to the chemistry of the body, for many reasons, that the blood and tissues should not be dehydrated. Therefore, as much water as possible should be given between the feedings, and if it cannot be administered in this way physiologic sodium chlorid solution should be given subcutaneously. Howland and Marriott believe that a large amount of the acidosis that is seen in these cases is caused by retention, owing to anuria, of acid sodium phosphate. Therefore, the free administration of fluid by keeping the kidneys active may prevent this complication or help to combat it when it has developed.

Sodium Bicarbonate.—We know now that a good many children with diarrheal disease die from acidosis. Acidosis is shown particularly by deep, tireless breathing, resembling that of air hunger. If this sign develops, sodium bicarbonate should be given at once, either by mouth, or, if not well borne by mouth, intravenously in the form of a 2 per cent. solution. Certain chemical changes take place in sodium bicarbonate after it has been sterilized, which make it very irritating, if given subcutaneously, so that it is never wise to give it in this way, unless a sterile salt is used, and added to the water *after the water has been boiled.*

Other Drugs.—Compound Chalk Mixture: This is, I believe, of value in many cases, as it helps in neutralizing the irritating acids that have been found in the intestine. The soluble alkalis are useless to give for this purpose as they are probably largely absorbed in the stomach, and never reach the intestine.

Opium: It is sometimes difficult to know whether or not to give opium. It is contraindicated if the bowel movements are very foul and few in number or if there is much evidence of toxemia. It is always contraindicated at the onset of an attack, as it is essential to empty the intestine and not to tie it up. In other cases it is distinctly indicated, and it is not good therapeutics to slavishly follow a set rule and to refuse to give opium in any case of diarrhea, as an experienced practitioner did with whom I saw a patient in consultation last summer. The child had been sick over a week, and was having from twenty to twenty-five loose, watery movements a day, with a great deal of straining and discomfort. She was much exhausted from all this, and still the doctor refused to give the small doses of paregoric I suggested because he "knew that it was always wrong to give opium in any diarrhea." In such a case as this, opium in some form, preferably paregoric, is distinctly indicated, for although diarrhea is undoubtedly a conservative process, it may exhaust the child so much that it does him more harm than good.

Bismuth: This drug is sometimes highly recommended, and again many authors say it is useless. It probably does more good in the true infectious type of diarrhea, when there is actual ulceration of the intestine, than it does in the fermentative type which we are discussing; in those diarrheas due to sugar fermentation, I should much prefer chalk mixture.

Stimulants: Stimulants are often needed, and there is probably none better than brandy or caffein. Epinephrin has been highly recommended by some, but its action is so transitory that its value seems somewhat doubtful, except to tide over a sudden collapse.

PROTEIN FORM OF FERMENTATIVE DIARRHEA

The protein form of fermentative diarrhea is not nearly so common as the carbohydrate form. In this condition the intestinal contents have been infected by bacteria which feed mostly on protein, and the resulting stools are brown and foul instead of being green and acid smelling. The general symptoms are similar to those of the carbohydrate form, but the differentiation of the two offers little difficulty owing to the difference in the stools. The treatment is the same as for the carbohydrate form, with the exception of the feeding. Here a low protein and a fairly high carbohydrate diet is needed. Ordinary milk modifications with low protein and high carbohydrate added in the form of lactose and starch sometimes work very well. This diarrhea is more likely to be caused by organisms introduced from without in bad milk than to any faulty digestion on the part of the baby.

III. INFECTIOUS DIARRHEA

In this disease we are dealing with a true infection of the intestinal mucosa, due to some specific organism, usually the dysentery bacillus, but occasionally the gas bacillus or streptococcus. Combined with infection of the mucosa, there may be also a certain amount of decomposition of the intestinal contents. The condition has been called by many names, but the term "infectious diarrhea" is the best one, as it serves to differentiate it from the fermentative group of diarrheas. Infectious diarrhea may arise in a number of ways, the most common one probably being direct infection of the mucosa by dysentery bacilli taken in per os. Or the process may in many cases start as a fermentative diarrhea, and for the first few days there may be no invasion of the mucosa. Then, if the organisms gain ascendance and are of the right variety, the mucosa is attacked, turning the fermentative diarrhea into one of the true infectious type. Occasionally a mechanical diarrhea, may change into an infectious, owing to the fact that the mechanical irritation of the intestine prepares the way and allows bacteria to invade the injured mucous membrane. There has been much discussion as to the organisms that cause infectious diarrhea, but the consensus of opinion seems to be that most cases are due to the dysentery bacillus. The streptococcus and the *Bacillus aerogenes-capsulatus* are also probably etiologic agents in some cases. Infectious diarrhea is a true epidemic disease, and is spread for the most part in the same way that typhoid fever is spread—by "fingers, food and flies."

In Boston, the epidemic usually starts the middle part of July, continues through August, and in especially hot summers into the first part of September. In the South it starts earlier, the last part of May and the month of June usually being the worst months. Young babies are by no means immune, but more cases of infectious diarrhea are seen in babies over 9 months old than in those under. The reverse is true for fermentative diarrhea. In fermentative diarrhea there is usually no demonstrable pathologic lesion of the intestine; in infectious diarrhea there may be a catarrhal inflammation of the mucosa of the ileum and colon, or innumerable small punched-out ulcers may be seen.

Symptoms.—The onset of infectious diarrhea is varied. It may be very sudden, and I have seen a case start with a convulsion and a temperature of 105, with no diarrheal symptoms until the next day. In most cases the onset is more gradual, however, and is first made known by diarrhea and moderate fever. There will usually be about eight or ten stools a day, but in some cases there may be as many as twenty or thirty. The stools may be very small, and often contain no fecal material, but consist merely of mucus, pus and blood. They are not usually offensive in character, and are more likely to be alkaline than acid in reaction, owing to the large amount of mucin they contain, which is a protein and decomposes rapidly. They practically always contain blood and pus intimately mixed with the mucus.

The condition varies a good deal in its severity; many patients do not have a temperature above 101, do not seem very sick, but still have many typical stools every day. Other patients will have extreme prostration, and may have a high temperature for a week or ten days. Nervous symptoms, such as twitching and retraction of the neck, are not uncommon, and are usually of bad prognostic significance. The body rapidly becomes drained of fluid on account of the diarrhea, and acidosis may develop, as shown by hyperpnea, in much the same way that it does in diarrhea of the fermentative type. In most cases gastric disturbance is not common, but occasionally there may be severe vomiting, which is very hard to deal with.

Diagnosis.—It is rare to have a case of infectious diarrhea without blood and pus in the stools, and for practical purposes this is the best way of distinguishing it from fermentative diarrhea. In the latter condition blood in the stools may be seen, but there is never much of it, and it never lasts for more than a day or two. Macroscopic pus is practically never seen in the stools in cases of fermentative diarrhea.

The temperature curve is also of considerable assistance in diagnosis. It may be high or low in either condition, but in fermentative diarrhea it rapidly drops as soon as the intestine is emptied and proper feeding instituted. In infectious diarrhea, on the other hand, the temperature is likely to continue elevated for several days, in spite of purgation and proper feeding.

Treatment.—The general treatment is the same as that for fermentative diarrhea, which has already been outlined. The principles of feeding, however, are quite different. As regards diet, cases of infectious diarrhea must be divided into two groups, for the feeding in the two groups is radically different. The first group includes cases caused by the dysentery bacillus or, more rarely, by the streptococcus. The second group of cases is caused by the gas bacillus.

As far as the symptoms and gross characteristics of the stools are concerned, it is impossible to tell into which group a given case falls. However, there is a simple stool test (see below) which serves to differentiate these groups. While the stool test is being made, or if for any reason it is not made, the case should be treated as a dysentery case, for this is by far the more common type. The therapeutic test is of some value, although rather haphazard, and if the child does not do well on the dysentery treatment, it should be changed to that for the gas bacillus. It is always best at the onset, however, to test the stools for the gas bacillus, as the test is simple and it gives much valuable information as to the proper feeding.

Technic of Gas Bacillus Test.—A U-shaped fermentation tube and a test tube are filled with concentrated nitric acid, and permitted to stand three minutes, when the nitric acid is poured out. Both tubes are rinsed thoroughly with tap water.

A small bit of stool, about a half teaspoonful of dextrimaltose, and about 15 c.c. of hot tap water are placed in the test tube, and the mixture is boiled vigorously for half a minute. The contents of the test tube are now poured into the fermentation tube, care being taken that it is filled up to the top, and that no air bubbles remain in it. The tube is plugged with flamed cotton, and keep in a warm place for twenty-four hours.

Gas in the top of the tube indicates that the gas bacillus is present, in greater or lesser numbers, depending on the amount of gas formed. If the gas bacillus is present in sufficient numbers to be the etiologic agent of the diarrhea, the tube will probably be "blown out," that is, entirely filled with gas.

Another simple way of testing for the gas bacillus is to plant a portion of stool in half a test tube of boiled milk and incubate twenty-four hours. If the gas bacillus is present the milk will be coagulated, will smell like rancid butter and will be shot full of holes like Swiss cheese.

If the "gas test" is negative, assume that the case is one of dysentery infection, and treat it as such.

FEEDING IN DYSENTERY CASES

The feeding in these cases is based on the fact that when offered protein food the dysentery bacillus grows very readily and produces large amounts of toxin. It does not thrive so well on carbohydrate food, nor does it produce so much or such deadly toxin. Therefore, a baby with dysentery should be fed on a low protein and a high carbohydrate food. This works well in practice, and is probably the most successful feeding known for dysentery patients. A few years ago it was the practice to starve patients with infectious diarrhea, and we used to feed many exclusively on weak barley water or lactose water for a week or ten days. Many of these patients died, probably as much from starvation as from the disease. According to our present ideas, a year old baby with dysentery would be treated about as follows: Following a purge, we give nothing but barley water for twenty-four hours. For the next twenty-four hours we add 8 per cent. lactose to the barley water. After this period a mixture of one fourth boiled skim-milk and three fourths barley water, with 8 per cent. lactose may be started. The skim-milk may be gradually increased each day, as the baby gets better, until he is taking undiluted boiled skim-milk with 8 per cent. lactose added. At about this time he should also be getting three or four tablespoonfuls of barley jelly a day. The skim-milk may be gradually replaced by whole milk, and the sugar should be reduced in quantity. During convalescence, fat should be increased very slowly, as nearly all babies after infectious diarrhea have a very poor fat tolerance. The sugars and starches should be most relied on.

It is quite likely that the baby will not digest all the food that is given him under this regimen, but he will come through the disease in much better condition than if he is starved, as he was in the former method of treatment. Another very successful method of treatment, which is similar in principle, and which has been used at the Floating Hospital in recent years with a good deal of success, is to feed the child on one-half fat-free lactic acid milk, and one half water, with lactose up to 8 per cent., the amount of lactic acid milk being gradually increased, and finally starches and fats being added. This method has the advantage that the lactic acid bacilli in the preparation may thrive to such an extent in the intestine that they will hamper the growth of the dysentery organisms.

The feeding in the "gas cases" is different, and patients with this form of infectious diarrhea always do better on lactic acid milk with a low sugar content than they do with any other feeding. The lactic acid bacillus seems to be directly antagonistic to the gas bacillus, and drives it out of the intestine very quickly. Furthermore, the relatively low carbohydrate and high protein content of lactic acid milk is indicated, as the gas bacillus is an organism which thrives on carbohydrate food, but does poorly on protein. Albumin milk, which has already been discussed, likewise fulfils all the indications for feeding in these cases.

PROPHYLAXIS OF DIARRHEAL DISEASES

No raw fruit or vegetables should be given to children under 5 years of age, and care should be taken that all food ingested be in a finely divided form. Overfeeding should be carefully avoided in hot weather, especially overfeeding with sugar. It is always good practice during a hot spell to dilute the baby's milk one third with water. Overclothing the baby is also to be avoided, and frequent bathing, avoidance of the sun, and providing him with water to drink between his feedings are all important. In the southern part of this country, during the summer, all milk fed to babies, no matter how clean it is, should be boiled. An ounce of orange juice daily will prevent scurvy.

In cooler parts of the country, during the hot weather, all milk should be boiled with the exception of certified milk, which can be given raw; but during very hot, sultry spells this should be boiled also.

There is really no valid argument against using boiled milk in the summer time. The only possible harm it can do is to produce scurvy. But we know that comparatively few babies who are fed on fresh boiled milk develop scurvy, and orange juice is practically certain as a prophylactic. Undoubtedly nature intended babies to have raw milk, but the dangers of unclean raw milk so greatly outweigh those of boiled milk, especially in the summer, that more and more physicians are ordering boiled milk as a routine, and it is the duty of us all to educate the laity as to the dangers of raw milk in hot weather.

POSTINFLUENZAL PSYCHOSES *

EGBERT W. FELL, M.D.
CINCINNATI, OHIO

During the recent epidemic approximately 2,500 cases of influenza were treated in the Walter Reed General Hospital. In 435 of these cases pneumonia either had already developed before admittance to the hospital or was diagnosed here during the course of the influenza. The number of deaths from pneumonia was 226, making the death rate 52 per cent. This includes practically all deaths from influenza and gives a mortality rate of about 9 per cent. for all influenza cases admitted.

Delirium occurring during the height of the disease and clearing with the cessation of fever (fever delirium) was more frequent in the early part of the epidemic when the more severe cases were seen. The features of this delirium were in no way peculiar to influenza, but were such as mark a hallucinatory confusion arising in the course of any infectious disease. Cases of this sort are not considered in this report. Neurasthenic depression frequently persisted for a longer or shorter period after the subsidence of the acute symptoms. When this depression was not sufficiently deep to be considered as constituting a psychosis, and to need special treatment as such, the patient was not transferred to the psychiatric wards.

Of psychotic states persisting after the subsidence of the fever, and requiring special attention, there were only four in the 2,500 cases of influenza. Three of these four cases presented pronounced pneumonic consolidation.

During the epidemic or since, in addition to these four, sixteen cases have been admitted to the psychiatric wards in the causation of which influenza seemed to play a more or less important part. Keeping in mind the tendency to attribute to an influenzal infection everything out of the ordinary that happens during

---

* From the Walter Reed General Hospital, Washington, D. C.

or following the epidemic, special care was taken to ascertain as definitely as possible that an influenza did exist or had existed. In our cases this was a comparatively easy matter since the fact of any illness would appear on the soldier's sick report. Recently a few cases have been admitted in which there was a history of influenza a month or more preceding the development of mental symptoms, during which interval the patient was in quite his normal condition. These cases are not considered in the present summary, nor is a case of frank delirium tremens running a typical course (second attack) and with only a vague history of a mild illness preceding it. Nor are definitely organic psychoses, coming to attention first at this time, considered as being due to the effects of influenza.

It is open to question as to how long after an influenzal attack that infection may be considered as an exciting cause in newly developing conditions. Since a new attack may occur within forty-eight hours, and the great majority of influenza patients are entirely well before the end of a month, we have assumed that if a soldier was sufficiently recovered to go back to duty and remain on duty for a month, the toxemia could be considered a thing of the past. Endogenous toxins liberated by the influenzal poison should show some effect before a month. In psychoses developing later than this there would be at least great doubt as to the etiologic importance of the infection. In none of our cases was the interval more than fourteen days.

The present report is intended to include only psychotic disturbances arising during the course of the infection and persisting for some time after convalescence, and those beginning during convalescence. The twenty cases which were selected as meeting these requirements had their onset as follows: During the febrile period: first week, 6; second week, 2; third week (pneumonia), 2; fourth week (pneumonia), 1; total, 11. During convalescence: first week, 5; second week, 4; total, 9. All were in soldiers (except one, a nurse) below 30 years of age, except two, who were 39 and 46 years old, respectively.

These cases fall quite readily into three groups: (1) Manic-depressive Group, eight cases; (2) Infective Psychosis Group, seven cases; (3) Dementia Praecox Group, five cases.

MANIC-DEPRESSIVE GROUP

Considering first the group in which the cases resembled most the manic-depressive picture, we find that three of the eight had their onset during the course of the influenza (fourth, fifth and tenth day) and that five came on during the first ten days of convalescence. In six there was a distinct hereditary factor and in two of these a history of prior attacks. One was mentally deficient. All were of the depressed type (except one nurse), began without disorientation, presented depression more or less deep, retardation, and self-accusatory ideas as the chief clinical features. Hallucinations of hearing occurred in only one and in that did not form an important part of the picture. The manic nurse ran the usual course of a mild mania until transferred at the end of a month to another hospital. Of the seven depressed cases five recovered in less than two months *with complete insight*, one is improving after two and a half months (mentally deficient), and one remains under treatment after four months. The following is a summary of the last mentioned case:

CASE 1.—A soldier, aged 30, whose father died from tuberculosis and mother from diabetes, and some of whose immediate relatives were said to be nervous, gave a history of a definite attack of depression in 1907 which resembled the present trouble. He contracted influenza Sept. 20, 1918, improved after six days, had a recrudescence of his temperature after four days which lasted seven days, at which time he had pulmonary findings suggesting tuberculosis but which later cleared up. Ten days after his fever subsided, about November 17, he became noticeably depressed, and worried about the people at home. He was retarded in thought and action. Two weeks later he was self-accusatory. He then continued without change until March 1, when he became more active but was still depressed. No hallucinations were apparent but he *complained of unpleasant thoughts coming* to his mind and of not being able to get rid of them. He thought a great deal about a skeleton. He worried about early sexual indiscretions. He said that when he was a boy he put his penis in his brother's mouth one night when the latter was asleep and that shortly afterward his brother died of *typhoid fever. He now blames himself for his brother's* death. After a duration of four months he appears more dull and is interested only in his own thoughts. He seems to appreciate that he is not right mentally.

Case 1 seems to form a connecting link with the praecox group. The quite definite history of a prior attack and the absence of hallucinations justify its being included in the manic-depressive group.

INFECTIVE PSYCHOSIS GROUP

In this group are included psychoses arising during the fever (and outlasting it) or at the termination of the fever. In none was there any important hereditary factor so far as could be learned. One case was in a constitutionally inferior individual of the inadequate personality type. One gave a history of a previous nervous attack. The chief symptoms consisted of more or less disorientation, sense falsifications (especially disagreeable voices), the mood was depressed rather than elated and restlessness was not a marked feature. The termination was by early recovery. The onset was on the second, third and fourth days in the uncomplicated cases, and on the twelfth, fourteenth, twenty-first and twenty-eighth days in the cases complicated by pneumonia (one antrum infection). The duration was as follows: Less than one month, two; less than two months, two; less than four months, three. In the four cases of short duration there was mental improvement in step with the physical improvement, and recovery was complete as regards insight, but there was not a clear memory of what had taken place at the height of the psychosis. Case 2 is an example:

CASE 2.—A soldier, aged 19, without known predisposition and no history of a prior attack of nervous or mental trouble, developed influenza, Sept. 30, 1918, the disease running a fairly severe course with bronchopneumonia. October 25, as his pulmonary condition was clearing up but while he was still in a run-down condition, he became depressed and disoriented: It was evident that he heard voices, though the exact content of these could not be ascertained. He accused himself of doing wrong and said that he was to be punished. He gradually improved physically, was less bothered by the accusations that he heard, and by the latter part of December was completely recovered. He appreciated that there had been something wrong with his mind, but he could not recall the details of the beginning and the height of his illness.

In other cases visual hallucinations with fear reaction were a prominent feature. One patient appeared to entirely lack insight on recovery, or at least he would never admit that there had been anything the matter with him. He was constitutionally inferior.

In the three cases of longer duration, four months, there developed after the delirium subsided, symptoms of a precox nature which made the diagnosis for a time uncertain. Summaries of these cases follow:

Case 3.—Student, S. A. T. C., aged 20, with no defective heredity and no history of prior psychotic attacks, developed influenza, Oct. 6, 1918. He was not seriously sick and improved sufficiently to go to work, October 14. Four days later he had a rise in temperature (antrum infection), became delirious, heard voices and saw strange things. November 2 he talked in a rambling way to himself of religious matters. When questioned, his replies were brief and irrelevant. He resisted examination and voided in bed. He was oriented approximately. In a week he grew less agitated and dropped religious subjects. He began having some trouble expressing himself and was decidedly sluggish in thinking and talking. He spent hours writing letters, scratching out and modifying what he had put down. The latter part of December he was in a catatonic state, refused to speak and had to be spoon fed, which condition alternated with unusual activity until February 1, from which time he improved steadily. He recovered, after four months' illness, with insight but with a defective memory for the early part and height of his illness.

Case 4.—A soldier, aged 24, without defective heredity or history of prior attacks, developed influenza, Sept. 24, 1918. On the fourth day of his sickness he began to hallucinate, heard voices say he was going to die, and saw a German digging a trench in which to bury him. He was poorly oriented. He improved quickly, but in the middle of December he still appeared somewhat confused and complained that he was unable to control his thoughts. He was restless, busied himself about nothing, was silly, laughing needlessly. He appreciated that things around him did not make the impression on him that they ordinarily would. There appeared to be a decreased flow of thought without definite blocking. At this time he did not hallucinate. He improved gradually and, Jan. 17, 1919, seemed perfectly well; he appreciated that his mental condition had been abnormal and he could recount many of the strange things that had happened to him.

Case 5.—A soldier, Italian, aged 23, no more emotional than the average of his race, developed influenza, Nov. 18, 1918. The next day he muttered incoherently when spoken to and seemed fearful. For the next six days he was more apprehensive and inaccessible, and had to be forcibly fed, evidently hallucinating. Negativism later became marked, and he lay in bed taking no interest in things around, and would not talk. He was not cleanly in his habits. He soon improved sufficiently to care for himself, but as late as the middle of January was still decidedly peculiar. He worried unnecessarily about his bodily functions, his talk was dissociated and meaningless, answers being often but vaguely related to the question asked. He gradually began to interest himself in things and by March 14 was active, interested, working, and his conduct seemed in all respects correct. He appreciated that he had not been just right, but he attributed his nervousness to the fact that since the influenza his bowels had not been in good condition.

Cases 3, 4 and 5 present sufficient praecox symptoms to connect them quite closely with the next, the dementia precox group.

DEMENTIA PRAECOX GROUP

Five of the cases, by reason of their most marked features, were considered as falling into this group. The onset in two was on the seventh and twenty-first days of the disease. In the three beginning during convalescence the onset was on the eighth day, after a sickness of fourteen days; twelfth day, after a sickness of sixteen days, and the fourteenth day, after a sickness of nine days. The duration at the present time is four, three and one-half, four and one-half, five, and four and one-half months, respectively. In none of the cases did heredity seem to be an important factor, nor was there a history of prior attacks. The onset was rather abrupt with more or less confusion. The mood was distinctly depressed and at times there was considerable apprehension caused by terrifying auditory and visual hallucinations. More or less distinct signs of blocking were present. Within two or three weeks the acute stage had passed and they have since pursued the usual hollow, inadequate course. Their reaction to messages by wireless, ideas of poisoning, accusations of being a German spy, bizarre sexual ideas, and feelings of bodily change is poor. They are now dull, lacking in interest, negativistic and promise to run the usual course of hebephronic dementia precox. In one case catatonic features were marked from the first but without any periods of excitement.

While these cases now seem to be clearly of the praecox type, their onset was not so different from that of the three infective cases that ran a long course (Cases 3, 4 and 5). One of the latter group was first called dementia praecox and one of the dementia praecox group was first called infective psychosis. Recent experience with praecox episodes following a definite adequate cause, as service with the A. E. F., would lead us to be in doubt as to whether in any individual case the condition will be permanent or whether ultimate (apparently) complete recovery might occur.

Considering the cases as a whole, predisposition did not seem to be a very important factor, only nine of the twenty showing defect of some sort either in the family or in the personal history. In only two of the eight manic-depressive cases did the family history seem to be entirely free from defect. Six had a history of nervous or mental trouble in immediate relatives and three of these had defective personal histories. Of the infective group two, these being cases of short duration, presented defective personal histories; heredity did not appear to be an important factor. In the five dementia praecox cases there was nothing in the family or in the personal history that could be considered as predisposing to mental trouble, except that in one case the father had become alcoholic late in life.

While the grouping of the cases may be said to be quite clear, there is distinct evidence of overlapping. Case 2, except for the initial disorientation, might have been considered as belonging to the depressed manic group. Cases 3, 4 and 5 presented praecox symptoms but recovered. The praecox cases in the beginning showed sufficient confusion to make the diagnosis for a time doubtful. In one depressed manic case (Case 1) praecox symptoms are beginning to appear. Disregarding the subdivision into groups and considering the series as a whole, the following gradations may be seen:

Depression; retardation; early recovery.
Depression; hallucinations; retardation; early recovery.
Depression; disorientation; hallucinations; early recovery.
Depression; disorientation; hallucinations; praecox symptoms; late recovery.
Depression; retardation; praecox symptoms; recovery doubtful.
Depression (+—); confusion (+—); hallucinations; praecox symptoms; no recovery.

Less marked than any of these is the simple neurasthenic depression that so frequently follows influenza. This would complete the gradations from a simple depression to a depressed hebephrenic praecox condition. Depression was by far the most common symptom, which seems to differ from the Boston Psychopathic Hospital experience[1] but is in accord with the view usually held.[2]

No individual case in the series presented anything that would mark it as being the result of influenza rather than of some other condition, but the mingling of symptoms resulted in a series that has features that seem to be rather characteristic of the postinfluenzal psychoses as we have seen them here. These features are: A foundation of depression with the superimposition of hallucinatory confusion and finally of schizophrenic symptoms.

SUMMARY

1. In an epidemic of influenza of average severity, occurring in soldiers who were for the most part between the ages of 20 and 30, only four of 2,500 cases treated at Walter Reed General Hospital developed psychoses of a severe type which outlasted the acute disease.
2. Twenty cases of postinfluenzal psychoses have, all told, been treated in the psychiatric wards of this hospital. They fall into three fairly distinct groups: Manic-depressive group, eight cases; infective psychosis group, seven cases; dementia praecox group, five cases.
3. Predisposition as shown by the family or the personal history was only marked in the manic-depressive group.
4. There is a sufficient overlapping of the groups to give, when considered as a series, a gradation from a simple depression to hebephrenic praecox of the depressed type. The chief characteristic of the series is: A foundation of depression on which develops sense falsifications, confusion and schizophrenic symptoms.
5. The occurrence of praecox symptoms is not a sure indication of permanency, but such cases run a longer course and recovery is less likely.
6. The most common symptom was depression. Hallucinations seemed to be entirely absent in seven cases.

Killing the Louse.—The louse is an insect of filth. The greatest problem in the sterilization of clothes is to kill all lice and vermin and all disease germs without injury to the garments, and when to sterilization can be added cleansing then we have the best process of all. The sterilization may be by dry heat, steam, hot water, gas or chemical wash, according to the available supplies. Steam sterilization may be accomplished in an autoclave, a room, a car, a kettle, a barrel or a laundry washing machine, by the use of vacuum or at normal or increased pressure in a closed cylinder, or it may be applied as live or current steam. In the acutoclave or sterilization cylinder the complete process requires half an hour, but it was found recently that in a laundry washing machine cooties and nits can be killed with current steam in fifteen minutes; remove the garments, shake them out and wear them. Current steam does not shrink in fifteen minutes in the laundry wheel. But steam, in whatever form, although effective, does not cleanse the garments. The laundry processes are thoroughly efficient delousing processes and each step in the laundry formula can of itself be so regulated as to kill all lice. If very resistant spore bearing bacilli are suspected of being in the clothes, a live steam sterilization may precede the wash with no injury to the garments.—W. D. Pierce, *J. Econ. Ent.* **12:** 46, 1919.

BLOOD TRANSFUSIONS WITHOUT A CHILL BY THE SYRINGE-CANNULA SYSTEM

TWO HUNDRED AND FOURTEEN CONSECUTIVE CASES

EDWARD LINDEMAN, M.D.
NEW YORK

During the past two or three years, several articles have appeared in the literature presenting one method or another of blood transfusion. In the presentation of such methods, naturally enough, claims of merit were made to justify the method used by the particular writer.

To one who may be inexperienced with blood transfusion, or who may not be familiar with the subject, such claims may be accepted without question. For this reason I deemed it timely to place on record the latest results obtained in transfusion of unmodified blood by the syringe cannula system. I trust future publications on methods of transfusion will refer to this article in making comparisons of methods.

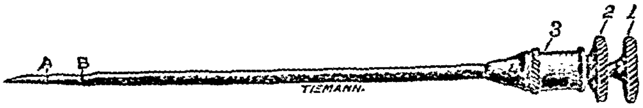

Fig. 1.—*A*, distal end of cannula 2; *B*, distal end of cannula 3.

The method as devised by me,[1] with only slight modifications, is as follows:

The entire apparatus consists of six syringes, two tourniquets, and two sets of cannulas.

CANNULAS

Two sets of cannulas are employed, one for the donor, the other for the recipient (Figs. 1 and 2).

There are three cannulas to each set (Fig. 2 *1, 2 and 3*). Each cannula telescopes within the other as shown in Figure 1.

The innermost cannula is practically a hollow needle, 2 6/16 inches long, 30-gage, with one end ground to a fine point and short bevel. The hollow needle (Fig. 2 *1*) is fitted snugly into Cannula 2. Cannula 2 is 5 mm. shorter than the needle and is fitted snugly into Cannula 3. Cannula 3 is 5 mm. shorter than Cannula 2. The proximal ends of Cannulas 1 and 2 are capped with stationary thumbscrew caps. The proximal end of Cannula 3 is capped with a receiver to fit any Record syringe.

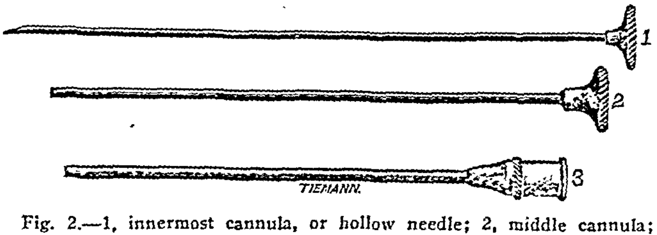

Fig. 2.—1, innermost cannula, or hollow needle; 2, middle cannula; 3, outer cannula.

Cannula 3 is 2 inches long, 14-gage, 0.064 diameter. The caliber of this cannula is the same as the tip of a Record syringe.

In very small infants with very small veins only Cannulas 1 and 2 are employed, Cannula 2 being capped with the receiver to fit the tip of the syringe.

The syringes can be sterilized in 95 per cent. alcohol for a period of ten minutes and then rinsed in physiologic sodium chlorid solution to remove the alcohol.

---

[1] Lindeman, E.: Simple Syringe Transfusion with Special Cannulas, Am. J. Dis. Child. **13:** 28 (July) 1913.

OPERATION

The patient and the donor are placed in recumbent posture in parallel position. The skin of the arms is sterilized. A small table is set between the patient and the donor. On this table are placed three basins containing sterile physiologic sodium chlorid solution approximately room temperature, for the washing of syringes. A nurse stands behind the table and washes the syringes by rinsing each syringe in each one of the three basins. As long as the last rinsing basin contains sterile normal salt solution, the other two may contain sterile tap or distilled water or salt solution. A syringe is never used a second time until washed in these basins, hence, no old or residual blood is allowed to enter the patient. These syringes are washed as rapidly as they are used. The third rinsing basin should remain clear throughout the operation.

One operator manages the syringe of the donor, the other operator that of the recipient. A tourniquet is placed on the arm of the patient to distend the vein. A cannula is then inserted into the vein by a skin puncture only.

INSERTION OF CANNULA

When the needle has entered the vein a drop of blood is seen to trickle from the distal end of the innermost cannula. After the first joint *A* has entered the vein, Cannula 1 is withdrawn about one-half inch, thus preventing the vessel wall from being punctured or injured by the needle after the vein is entered.

With the thumb now on the screw-cap of Cannula 2, the cannula is forced further until joint *B* has entered the vein. Cannula 2 is then withdrawn a distance of one-half inch, Cannula 3 alone now coming in contact with the vessel wall. The latter is then gently pushed into the vein to a desirable length, usually from three-quarters to one inch. The tourniquet is then removed.

A cannula is then inserted into the vein of the donor in a similar manner. The tourniquet is placed on the arm sufficiently tight to obstruct the venous return, but not tight enough to impede the arterial flow, and remains on the arm of the donor throughout the operation. Everything is now in readiness for transfusion. There is no need of haste at this stage.

The obturator in the cannula of the donor is removed and an empty syringe is promptly attached and blood is withdrawn as rapidly as possible. When the syringe is filled, the assistant replaces it by an empty syringe, at the same time placing the filled syringe on the table. The operator places his thumb over the mouth of cannula to prevent leakage during change in syringes.

The operator on the recipient picks up the filled syringe, attaches it to the cannula after removing the obturator, and evacuates the contents gently but speedily into the vein. As soon as the contents are evacuated a full syringe is again ready for evacuation. One syringeful of blood follows another in rapid succession until the desired quantity of blood has been transfused.

Small syringes of 20 c.c. capacity are found most satisfactory. Larger sizes are not used because it requires a longer time to fill and empty them. The time elapsing for the filling and emptying of one syringe is from six to ten seconds. It is practically impossible for any chemical or physical change to take place in that short space of time. Since the blood is transplanted in relay fashion, the entire mass of blood, regardless of the amount, is outside the body only so long as it takes to fill and empty one syringeful, namely, from six to ten seconds.

A little of the salt solution is squirted around the cannula occasionally to keep the field clean but none is injected into the vein of the patient.

ADVANTAGES OF THE METHOD

The blood passes through a minimum amount of foreign material. There is no blind system into which air may leak, and there are no rubber tubings, stopcocks or valves around which blood may clot. No anticoagulants and no foreign material are introduced into the patient. Herein lie the merits of this method.

In the method as originally outlined, a little of the salt solution was injected into the vein of the patient from time to time during the operation. This has been found unnecessary and during the past two years has been discontinued.

Before the publication of the syringe-cannula system of blood transfusion, I devised a variety of other methods, such as force-pumps, and gravity-pumps attached to intravenous cannulas by means of rubber tubing. I had also at that time, at the suggestion of Dr. Cyrus W. Field of New York, used sodium citrate to prevent the coagulation of the blood. These were all found inferior and were discarded by me in favor of the syringe-cannula system.

Since the publication of this method I have looked for possibilities for further improvement. I have continued experimenting for simplification, also realizing at the time that many others would attempt this. But I soon learned that further simplification was not attained without the sacrifice of important points of merit in the original method.

ESSENTIAL FACTORS

The important factors essential in the proper transplantation of blood are: (1) The method must be applicable in any case and in any disease. (2) It must be possible to transplant any amount necessary to obtain the most desirable clinical results. (3) The blood must be transplanted exactly as it exists in the donor, namely, in its natural state; to do this, (4) it must pass through a minimum amount of foreign material; (5) it must be out of the body of the donor and into that of the patient in a minimum length of time, and (6) it must be free of reactions.

REACTIONS

There are at least four causes for reactions to be recognized in blood transfusion: (1) hemolysis and agglutination; (2) toxic substances developed in the blood on remaining outside of the body; (3) chemicals such as anticoagulants and physiologic sodium chlorid solution, and (4) sensitization and anaphylaxis.

In the first 150 transfusions performed by me by the syringe-cannula system, a record of which has been published,[2] 33 per cent. were followed by chills and fever. In that series the preliminary hemolytic tests were made by many serologists in many parts of the country. At that time serologists, generally, were unfamiliar with these tests and the work was done rather crudely. The question I naturally asked myself was, Was the cause of these chills due to the method or was it due to inaccurate laboratory work in the selection of donors?

I then set myself to the task of supervising all hemolytic tests myself in order to rule out variations in the personal equation of laboratory workers.

I then published reports[3] on a series of 155 transfusions by the syringe-cannula system. Of this series the blood tests were personally supervised by me in 146 transfusions. Nine per cent. of these were followed by chills. In all, 136,800 c.c. of blood were transfused without a death referable to transfusion.

---

[3] Lindeman, E.: Reactions Following Blood Transfusion by the Syringe Cannula System, J. A. M. A. **66**: 624 (Feb. 26) 1916.

Adults received from 1,000 to 1,800 c.c. of blood in each operation.

I was much impressed by this marked improvement in the results obtained and concluded that chills in blood transfusion by the syringe-cannula system were the result of slight grades of hemolysis due to poor choice of a donor. Incidentally the technic was improved, so that it was no longer necessary to inject salt solution into the patient and the 9 per cent. of chills were eliminated. The last series cited in the tables comprises 214 consecutive transfusions without a chill.

TABLE 1.—BLOOD TRANSFUSIONS IN THIRTY-ONE CASES OF PERNICIOUS ANEMIA

Rise of Temp.	Amount of Blood Transfused 1,000 C.c.	1,100 C.c.	1,200 C.c.	1,300 C.c.	1,400 C.c.	1,500 C.c.	1,600 C.c.	1,700 C.c.	1,800 C.c.	2,000 C.c.	2,200 C.c.	Total Transfusions
No rise....	..	..	..	1	1	3	..	..	..	..	..	5
1 or less...	..	2	1	1	2	2	2	..	..	..	..	10
Under 2...	3	6	6	9	7	10	7	..	..	..	1	49
2 to 3......	1	3	4	3	8	2	2	..	..	1	..	24
3 to 4......	..	2	3	..	1	3	1	..	1	..	..	11
4 to 5......	..	1	1	..	2	..	1	1	..	..	..	6
5 to 6......	..	..	..	..	..	1	2	..	..	..	..	3
Totals..	4	14	15	14	21	21	15	1	1	1	1	108

In order to make this demonstration obvious, transfusions of less than 1,000 c.c. are omitted in this series, and the sequence is disturbed by the absence of citation of cases receiving smaller amounts. The amounts transfused are shown in the accompanying tables. The tables represent two hundred and fourteen transfusions, in which 270,400 c.c. of blood were transfused.

The posttransfusion temperature is more often somewhat higher when amounts are transfused above 1,400 c.c. Some transfusions of large amounts show less rise of temperature than other transfusions of lesser amount. The rise of temperature usually begins from two to four hours after transfusion and begins to decline from four to eight hours afterward. In three cases a rise of temperature of from 5 to 6 degrees continued during a period of twenty-four hours after transfusion and then declined gradually until normal was reached three days later. One case had a delayed rise of temperature beginning almost twenty-four hours after transfusion and continuing for two days. During the period of fever of 3 degrees or more, patients will sometimes have a feeling of malaise and lack of appetite; at other times, exhilaration, restlessness and sleeplessness. When the temperature reaches normal, the full benefit of the transfusion is felt as a rule, and any symptoms incident to the procedure disappear. A transitory urticaria occasionally occurs but is apparently of little consequence. A transfusion at one time may be followed by an urticaria, yet at another time it may be absent in the same patient.

In four instances bronchospasm occurred, in two instances following the first transfusion, once in a case of leprosy and once in a patient who was asthmatic. The third instance occurred after the patient received his fifteenth transfusion, when 1,600 c.c. were transfused. The fourth instance occurred after the fourteenth transfusion, in which 1,500 c.c. were transfused. All of these cases were followed by only moderate rise of temperature and no chills. The third patient received three transfusions subsequent to his attack, with one recurrence and then only to a lesser degree. The fourth patient has had five transfusions since his attack of bronchospasm, without recurrence.

Of the 214 transfusions, there were 108 in pernicious anemia (Table 1). On some of these patients transfusion was performed from fifteen to twenty times. There was in 18.5 per cent. a posttransfusion rise of temperature of 3 degrees or more. The patient receiving 2,200 c.c. had a rise of less than 2 degrees and returned to his home, about 150 miles distant, thirty-six hours after receiving the transfusion, feeling well. There were twenty-six transfusions in cases of hemorrhage (Table 2). There was a rise of temperature of 3 degrees or more in 12 per cent. of these cases. One patient receiving 2,000 c.c. had a rise of temperature of less than 3 degrees. There were eighty transfusions in the miscellaneous group (Table 3). Of these 12.5 per cent. had a rise of temperature of 3 degrees or more.

The number of transfusions in the two latter groups (Tables 2 and 3) combined is the same as in the pernicious anemia group (Table 1), yet the pernicious anemia group shows a somewhat higher percentage of instances of posttransfusion temperature of 3 degrees or more. It should be noted that in the pernicious anemia group there were a greater number of instances in which patients received larger amounts of blood. I am inclined to believe that the larger amounts rather than the disease is responsible for the small increase in percentage. It is seen by the tables that by the syringe-cannula system blood may be transplanted with very near approach to the ideal. It may be transfused in any quantity and the very disagreeable and undesirable reactions many times following transfusion may be avoided.

RESULTS IN CITRATE METHOD

Recently the use of sodium citrate has come into favor of some. One need only refer to such articles as Novy and DeKruif,[4] Drinker and Brittingham[5] and the work of Clowes,[6] to appreciate the inferiority of the citrate method in comparison with that of unmodified blood. Even some of its most ardent supporters recognize the frequency of chills after citrate transfusion. At the outset attention should be called to the fact that in blood transfusion by the syringe-cannula system a given mass of blood is out of the body of the donor and into the patient before the same mass of blood by the citrate method even reaches the citrate solution.

TABLE 2.—BLOOD TRANSFUSIONS IN FOURTEEN CASES OF HEMORRHAGE

Rise of Temp.	Amount of Blood Transfused 1,000 C.c.	1,100 C.c.	1,200 C.c.	1,300 C.c.	1,400 C.c.	1,500 C.c.	1,600 C.c.	1,700 C.c.	1,800 C.c.	2,000 C.c.	2,200 C.c.	Total Transfusions
No rise....	..	1	5	..	1	..	..	..	..	..	..	7
1 or less...	..	1	1	1	1	..	1	..	..	..	..	5
Under 2...	1	2	..	..	..	..	..	..	..	..	..	3
2 to 3......	2	1	1	1	1	1	..	..	..	1	..	8

5 to 6......	..	..	..	..	..	1	..	..	..	..	..	1
Totals..	3	6	7	2	4	2	1	..	..	1	..	26

Drinker and Brittingham[5] showed that when they introduced into a patient citrated blood from which the platelets had been separated, the percentage of chills was less than when the citrated blood with platelets was introduced. When they isolated the platelets from citrated blood and introduced them into a patient they produced reactions. They conclude that when blood is citrated the platelets undergo some change and that this change in the platelets is responsible in a measure for the chills. They also demonstrated that mere addition of sodium citrate to red cell suspension increases the susceptibility to chills and these red cells also hemolyze more readily.

[6] Clowes, G. H. A.: J. Phys. Chem. **20**: 407, 1916.

Clowes[6] has called attention to the similarity of sodium chlorid and sodium citrate and to their general effects on protoplasm. He showed that the difference between the salts is a function of the anion, and citrate is infinitely more toxic than the chlorid, no matter what the test material.

The clinical results of a single injection of sodium citrate into the circulation of an individual is by no means any proof of its harmlessness when added to blood outside of the body. In the first place, while injecting such citrate it is possible for the bodily mechanism to neutralize or convert it before any injury has been done to the blood itself. Secondly, when such chemicals are added to so labile a substance as blood and the blood is allowed to stand outside the body for from twenty minutes to one hour or several hours, a wholly different set of circumstances pertain.

It may be here worth while quoting Novy and DeKruif[4] on the explanation of the production of anaphylatoxin. They believe the matrix of the poison anaphylatoxin is in the plasma and the serum. They say:

> The disturbance which brings about the transformation of the matrix into poison is readily affected by the addition of almost any alien substance to a serum. Thus bacteria, cells, organ extract, peptone, agar, starch, silicic acid, barium sulphate, diverse salts, even distilled water act as inducers or accelerators of this action. As to the mode of action of these substances, nothing definite can be said, but it is probable that a dispersion of the matrix precedes a tautomeric change.

Novy and DeKruif also showed that toxic substances develop in blood on standing for a period of three minutes. The reaction to this toxicity would be a mass reaction and would vary with the quantity introduced. A given patient may escape a severe reaction on a small quantity of citrated blood, say 500 or 600 c.c., but in many instances he would suffer a severe reaction if given a larger amount. The quantity of blood, therefore, that it is desirable or possible to introduce by the citrate method is necessarily limited to small amounts in order to remain within the limits of reasonable safety. Naturally sponsors for the citrate method would advocate a small transfusion in any condition regardless of the specific clinical demand because only small transfusions are possible by the citrate method.

It is therefore unfair to make comparisons of the incidence of chills following transfusions of citrated blood and those following transfusions with unmodified blood unless the amount transfused is taken into account. If comparisons are made in cases in which from 1,000 to 1,200 c.c. or more are transfused, the incidence of chills by the citrate method is very high and may be followed by death, and that by the syringe-cannula system, as shown by the tables, is absent.

The conclusion must follow that citrate of soda must produce changes in the blood, or allow by its use changes in the blood to develop, which produce chills and severe reactions. Furthermore, the inferiority of citrate transfusion is not only expressed by the incidence of chills and by the limitations of the amount it is possible to introduce into a given patient with safety, but is also expressed in the danger to patients of sensitization for subsequent transfusions, by the introduction of toxic substances into the patient. Toxic substances may produce chills and fever, and they may also cause sensitization. The subsequent introduction of toxic substances may produce bronchospasm, angioneurotic edema. The latter may become general and be followed by death. I have seen angioneurotic edema follow in two cases in patients who had previously received citrate transfusions, but in no instance has it followed in any case in which I transfused unmodified blood by the syringe-cannula system.

REPEATED TRANSFUSIONS

In diseases in which repeated transfusions are necessary, each transfusion should be done as nearly perfectly as possible to avoid disturbance of the labile elements in the blood and to avoid the sensitization of a patient to subsequent transfusions.

When one reflects on this subject and realizes the many factors that are involved in blood transfusion, namely, blood coagulation, platelet change, susceptibility of red blood cells to hemolysis, the danger of alien substances producing anaphylatoxin, anaphylaxis, tautomeric changes, the effect of chemical substances on the immunologic properties of blood, etc., it might impress itself on some that it would be worth while before doing transfusion work to pause a moment in reflection on the best method for the transplantation of blood.

When one does such work only occasionally or rarely, the less one does of it, the better for the patient, and any method which meets the inexperience or limited technic of the operator is advisable. But when such work is done frequently, the operator should be encouraged to train himself to become equal to the best method that will make possible the closest approach to perfect transplantation. To do this I believe the method must embody the following qualifications: (1) The blood must be out of the body a minimum length of time; (2) it must pass through a minimum amount of foreign material; (3) anticoagulants must be avoided; (4) no foreign material, not even physiologic sodium chlorid solution, should be introduced; (5) it must be applicable in any case and in any disease, and (6) it must be possible to transfuse in any amount with a minimum reaction.

Blood transfusion is a life-saving measure and one that will frequently yield brilliant results in the hands of the skilled and failure in the hands of the inexperienced. It is especially in diseases other than hemorrhage, when there is much disease for the patient to overcome after he has received the most effective transfusion obtainable, that work of high excellence is of paramount importance.

565 Park Avenue.

PREGNANCY COMPLICATED BY EPIDEMIC INFLUENZA

PAUL TITUS, M.D.
Obstetrician to the Western Pennsylvania Hospital, Pittsburgh; Professor of Obstetrics, University of Pittsburgh
AND
J. M. JAMISON, M.D.
Resident Obstetrician, Western Pennsylvania Hospital, Pittsburgh
PITTSBURGH

Influenza and pneumonia are, without any question, extremely grave complications of the pregnant state. Until the recent outbreak of epidemic influenza, however, there seems to have been either little opportunity or no great effort to study any number of such cases appearing in groups in which the infective organism, seasonal conditions and general treatment were similar. Following the epidemic of 1889-1890 a few articles appeared in various European journals, but the opinions and findings of the different writers were not especially convincing nor were they by any means uniform. Most of the articles were published long after the epidemic was past and interest had died down, so that they were merely of historical value and the lesson in them was lost. Consequently, with the outbreak of the recent epidemic we were quite unprepared for the appalling loss of life among pregnant women affected by this disease. Hintze,[1] Vinay,[2] Ballantyne,[3] and Amann[4] studied the effects of the epidemic of 1889-1890 and published their results, but for the most part their conclusions were inconclusive, while a review of their work leaves many points unexplained and considerable doubt as to just what course should be pursued in the care and treatment of any given patient or number of patients.

RELATION OF PNEUMONIA TO EPIDEMIC INFLUENZA

We have made an analysis of fifty cases of pregnancy complicated by epidemic influenza and believe the study to be of value, not only from the standpoint of interest in the present epidemic, but also in its relation to ordinary pneumonia during pregnancy. The generally accepted idea regarding this disease has been followed in that we have made no attempt to differentiate between those cases which did and those which did not show pneumonic lesions, classifying them all under the heading of epidemic influenza. Clearly many of the lessons to be learned from this epidemic can be applied to the more usual types of pneumonia. That there is a need for such application is demonstrated by the discussion of the recent work of Bland[5] on such a self-evident point as the effect of abortion or premature labor on the course of the disease. Bland showed that 75.5 per cent. of the women in whom the disease was fatal died after their pregnancy was interrupted, but Arnold,[6] in discussing his paper, stated that abortion or miscarriage was not to be feared but welcomed, and considered artificial termination of pregnancy advisable in order to lessen the toxemia of the patient. Farrar[7] and Kosmak[8] both believe that abortion has little or no influence on the course of the disease, although Kosmak thinks that induction of labor should not be undertaken, because labor at this time is simply an added burden for the patient to carry.

In our series, several peculiar features stand out with especial prominence, and we wish to emphasize these, at the same time endeavoring to explain them, hoping that something of value in the way of treatment may be gained thereby. It was evident from the outset that it was a serious matter for a pregnant woman to develop epidemic influenza; it soon was learned that a large proportion of these women miscarried, or fell into labor, prematurely or otherwise, as a direct result of the infection, and the mortality, high enough without this occurrence, was thereby increased to a shocking degree. We have known this more or less vaguely from the usually tragic course of pneumonia during pregnancy as seen in routine practice. The epidemic of influenza, however, acted like a veritable plague, carrying off pregnant women as it did no other class of people.

EFFECT OF INFLUENZA ON PREGNANT WOMEN

Among the fifty patients, an interruption of pregnancy as a direct result of the infection took place in twenty-one, or 42 per cent. Seventeen of these women died, and only four recovered. This is a mortality of 80.9 per cent. in case the patient delivers herself or miscarries, and may be compared to the incidence of death in the group of twenty-nine women whose pregnancy was undisturbed. Fourteen, or 48.2 per cent. of these died undelivered, whereas the remaining 51.8 per cent. recovered without any apparent effect on their pregnancy.

In recapitulation, our figures may be expressed in three ways, namely, 48.2 per cent. mortality resulted

under the best possible circumstances, that is, without disturbance of the pregnancy; 80.9 per cent. if the disease interrupts the pregnancy, or an average risk to a pregnant woman from epidemic influenza of 62 per cent. (thirty-one deaths among fifty patients).

During the epidemic 950 patients with influenza were admitted to the Western Pennsylvania Hospital of Pittsburgh. The mortality among these patients was 22.31 per cent., which is somewhat lower than that reported by Keeton and Cushman[9] of the Cook County Hospital in Chicago, where there was a death rate of 39.3 per cent. among 1,735 patients. Although their total mortality was higher than that of the Western Pennsylvania Hospital, the death rate among pregnant women in the same institution was lower than ours. This was reported by Woolston and Conley[10] as being 51.4 per cent.

In studying the total mortality at the Western Pennsylvania Hospital, it was noted that the incidence of death was higher (24.84 per cent.) among nonpregnant women than among men (19.1 per cent), but the 62 per cent. death rate among pregnant women is still two and one-half times greater than that of other women.

Table 2 demonstrates the facts already stated, that a pregnant woman who contracts epidemic influenza is liable to have her pregnancy interrupted by the disease, and that if this does happen her chances for recovery are seriously impaired.

TABLE 1.—MORTALITY IN INFLUENZA *

	Mortality at West. Penn. Hospital, Per Cent.	Mortality at Cook County Hospital, Per Cent.
All cases	22.31	39.3
Pregnant women	62.0	51.4

* A few of our cases occurred in the obstetric service (Dr. Titus) of the St. Margaret Hospital, Pittsburgh. The treatment having been identical, they are included.

EXPLANATION OF INTERRUPTION OF PREGNANCY AND ITS EFFECT

In seeking an explanation of these two points, observers have advanced several theories. Woolston and Conley[10] believe that the toxemia which exists is largely responsible for the frequency with which pregnancy is interrupted, and refer to the lack of proper oxygenation of the blood as a causative factor. They note that a very great majority of abortions or premature labors occurred within twenty-four hours of death, at which time patients were extremely toxic, and reason therefore that the imminence of death is a cause rather than an effect of the abortion or premature labor. We do not quite agree with this, because we believe that the toxemia acts entirely in an indirect way in interrupting a pregnancy, and that death is hastened by this occurrence.

Among our patients, fourteen women died undelivered, all necessarily "toxic," as compared to seventeen, only three more, who aborted or delivered and then died. Toxemia should be considered only as a factor in the production of uterine contractions, else there would have been more deliveries among the fatal cases. At least the term is too general and its use does not explain the manner in which a toxemia actually affects pregnancy. Every one is familiar with certain ordinary toxemias of pregnancy, none of which cause premature labor, except indirectly. For instance, preeclamptic toxemia seldom causes labor to begin unless the fetus dies. Many women commence to have labor pains during a series of eclamptic convulsions, but that is due in all likelihood to the violence of the convulsive seizures in conjunction with the death of the fetus, which thus becomes a foreign body within the uterus. Toxemia alone, therefore, cannot be said to produce premature labor.

TABLE 2.—INTERRUPTION OF PREGNANCY AND RESULTS

		Month of Pregnancy									Mortality Per Cent.
		2	3	4	5	6	7	8	9	Total	
Recovered	Interrupted	0	1	0	0	0	0	0	3	4	....
	Uninterrupted	0	0	2	2	3	4	3	1	15	....
Died	Interrupted	0	0	2	1	5	1	1	7	17	80.9
	Uninterrupted	1	0	1	3	3	4	0	2	14	48.2
Total		1	1	5	6	11	9	4	13	50	62.0

It naturally requires little impulse, in a comparative way, to start a woman near term into labor, and if one accepts the theory of Brown-Séquard[11] that an excess of carbon dioxid and a lack of oxygen in the blood leads to energetic uterine contractions, we have a ready explanation of the labors at or near maturity. Nine babies from these labors survived; one died. There seemed to be a tendency, however, for pregnancy to be interrupted no matter what the period of gestation (Table 2). In the earlier months, something more is required, and it seemed logical to conclude that here was a combination of factors, such as deoxygenation of the blood, and increase in carbon dioxid to such a degree that it and the toxemia of the mother brought about the death of the fetus, which immediately acts as a foreign body within the uterus and, setting up contractions, is presently extruded.

The fact that Table 3 shows that ten of eleven premature infants were born dead, as compared to only one baby in ten at full term, would indicate that it is almost necessary to kill the fetus by deoxygenation and toxemia in order to interrupt the gestation in the earlier months.

TABLE 3.—CONDITION OF INFANTS

	At or Near Term	Premature
Born alive	9	1
Died	0	1 (22 hrs.)
Survived	9	0
Born dead	1	10
Recent	1	8
Macerated	0	2

This idea is further borne out by the fact that most of the patients who had premature labors or miscarriages induced by the infection died within from twelve to twenty-four hours after delivery (average time approximately twenty hours), whereas following labor at or near full term death occurred at any time from two to twenty-one days (average time eight days). Evidently, therefore, a patient must be more seriously ill to start a miscarriage than to start labor at term. We reason thus because death followed more promptly in that group of cases in which the actual amount of work and shock incident to labor naturally would be least. In fact, the abortions, miscarriages and the earliest of the premature labors were apparently easy for the patient. Of course, many of the women were so toxic that they may have been indifferent to the pain.

EFFECT OF INTERRUPTION OF PREGNANCY

Interruption of pregnancy at any period is serious, but it is less serious at term, because less toxemia and deoxygenation of the blood is required in order to bring on labor at this time. Because this patient is not necessarily so seriously ill as one of the other group, her chances for recovery should be slightly better. Table 2 shows this to be true. It will be noted that ten patients delivered before the ninth month died, while only one recovered; whereas only seven died following delivery at term, while three recovered. Just why so many as fourteen women died undelivered can be explained only by saying that in them the disease advanced so rapidly that it outstripped the more laborious process of the induction of abortion or labor. By this we mean literally that it is a time-consuming process to get ready for even the beginning of a labor or abortion to say nothing of the time which is later involved in the completion of the labor after it is once begun. Labor had begun in only one of the fourteen patients who died undelivered.

The next question which arose was why the mortality should be so great and death so sudden when an interruption of pregnancy takes place. As pointed out above, the 48.2 per cent. mortality in pregnant women is increased to 80.9 per cent. by the mere occurrence of a miscarriage or an easy labor. We have argued, it is true, that the more seriously ill a woman is the more likely, as a result of this, is she to have her pregnancy interrupted, and this might appear to dispose of the question. That would be so were it not a matter of comparison. The more profoundly sick a woman is, the more certainly and the sooner will she miscarry or go into labor; but no matter how light any given woman's illness might be, if she has her pregnancy interrupted by the disease the outlook for her immediately becomes more grave. We had gained the impression, later borne out by our figures, that of two women equally ill, the one whose pregnancy remained undisturbed possessed a likelihood of recovery several times as great as that of the woman whose pregnancy was interrupted. This impression was due to the fact that practically all of the former who died were seriously ill on admission to the hospital, whereas many of those in the latter group seemed to be in fairly good condition until the moment when their pregnancy came to an end. From that instant their general condition became steadily and rapidly worse. The internist in consultation in several of the latter cases gave the opinion that "there was not enough pneumonia present to kill this woman," or "from a medical standpoint her condition was quite good." Almost invariably, however, the ending of their pregnancy was marked by a distinct change for the worse, usually followed by death.

The explanation of this seems to be that labor or even miscarriage is accompanied by a certain amount of shock, and on delivery there is a sudden lowering of intra-abdominal pressure, especially if pregnancy is at all advanced. The muscular effort of labor increases the carbon dioxid content of the blood, already overloaded through the deficiencies of the respiratory tract; the myocardium is weakened by the disease, then strained by the muscular exertion of labor, after which blood pressure is suddenly reduced by the cessation of labor and the hemorrhage accompanying delivery.

This matter of hemorrhage is probably a most important factor. Venesection, while theoretically advisable in ordinary pneumonia, has been shown to be actually harmful to patients with epidemic influenza. The cyanosis of these patients is more a dusky pallor than a blueness. Circulation is undoubtedly impaired, and we found that the lower the blood pressure the worse the prognosis. Patients who recovered maintained a fair blood pressure, whereas those who died either started out with or soon developed a low blood pressure. As patients began to recover blood pressure increased. Venesection in these cases is illogical, therefore, and the loss of blood accompanying delivery or miscarriage undoubtedly has a deleterious effect on these women.

AGE OF PATIENTS

It may be of passing interest to speak of the ages of the patients studied in this series. As our youngest patient was 17 years old and our oldest 37, we divided them into two groups, each of ten years. There were twenty-nine women from 17 to 27 years of age. Ten, or 34.5 per cent., of these recovered, as compared to nineteen, or 65.5 per cent., who died. In the group whose ages ranged from 28 to 37, there were eighteen women, of whom ten, or 55.5 per cent., recovered, while eight, or 44.5 per cent., died.

The practical points to be gained from this study may best be outlined in a summary.

SUMMARY

1. The recent outbreak of epidemic influenza offered an opportunity for the study of numbers of pregnant women attacked by the disease.
2. Pneumonia and epidemic influenza complicating pregnancy have so many features in common that a study of the latter is of value, for its application not only to future epidemics, but also to the management of ordinary pneumonia as seen from time to time in pregnant women.
3. The mortality from epidemic influenza in pregnant women is much greater than in nonpregnant women.
4. Epidemic influenza caused abortion, miscarriage or premature labor in approximately 42 per cent. of the patients in this series.
5. The outcome of the case depends largely on the effect of the disease on the pregnancy, as evidenced by the fact that the mortality among pregnant women, high enough under the best possible circumstances (48.2 per cent. without interruption of the pregnancy), was markedly increased (80.9 per cent.) by the occurrence of abortion, miscarriage or premature labor.
6. The mechanism by which the disease disturbs the pregnancy seems to be a combination of factors such as deoxygenation of the blood, excessive accumulation of carbon dioxid in the blood, and a degree of toxemia sufficient to cause the death of the fetus. In the later months, the first two conditions may be sufficient to start labor, but in the earlier months it usually requires the additional condition of a dead fetus acting as a foreign body to initiate uterine contractions.
7. The ill effect of abortion or labor on the course of the disease may be explained on the following grounds: (*a*) muscular exertion increasing the already

excessive amount of carbon dioxid in the blood, and further straining the already weakened myocardium; (*b*) sudden release of intra-abdominal pressure by the extrusion of the fetus in an advanced pregnancy; (*c*) sudden reduction of blood pressure by hemorrhage incident to labor; (*d*) lessened resistance to the ordinary shock of labor and delivery.

8. The treatment should be primarily prophylactic, pregnant women being urged to avoid all possible exposure to cases of influenza or pneumonia or even common colds. In case of infection the patient should have absolute rest, fresh air (out of doors if possible), early stimulation, free elimination, avoidance of violent purging and quinin, sedatives as required, and in case labor or miscarriage comes on, early interference in order to relieve her as much as possible of the strain of the second stage. To this end forceps delivery is advised, as soon as the cervix is dilated, since the abdominal as well as the uterine muscles are in action in the second stage and the exertion, therefore, greater. Anesthesia is, of course, contraindicated and not required, because the patients are usually so toxic as to be indifferent to the pain whether the delivery be instrumental or spontaneous. Prompt measures against hemorrhage, such as uterine pack, should be instituted. Hypodermoclysis of physiologic sodium chlorid solution is frequently used and is probably preferable to intravenous injection, because the circulatory system must not only not be overloaded, but also not too suddenly strained.

ABDOMINAL PREGNANCY CONTINUING FOUR MONTHS AFTER UTERINE PERFORATION

OPERATION AND RECOVERY

I. EDWARD BISHKOW, M.D.
Associate in Surgery, Mt. Sinai Hospital
CHICAGO

The unusual course and findings of this case, and its extreme rarity, warrant the careful, detailed report.

REPORT OF CASE

History.—Mrs. L. S., aged 25, married five years, began menstruating at the age of 14. The first child, born in 1915, was a forceps case and died in one week from cerebral hemorrhage. The second child, born in 1916, is living and well. From the time this second child was 10 months old, the mother had menstruated regularly up to the early part of December, 1918. The latter part of December, two weeks following her menstrual period, her husband died of influenzal pneumonia, and when she failed to menstruate in January, she went to a midwife, who introduced a soft rubber catheter into the uterine cavity, where it remained for two days. One week later this was repeated and she then bled for three days. Two weeks after abortion she entered the Bellevue Hospital, New York, because of abdominal cramps and epigastric pressure, and remained there one week. She refused to have curettage performed and left the hospital. In March she came to Chicago and at the end of the month entered the Michael Reese Hospital, where she remained three days under observation. She left the hospital and went to work in a tailor shop. In both hospitals she denied any abortive measures had been attempted and gave misleading statements. During January, February and March, at her regular menstrual periods, she flowed for two or three days, but the flow was dark and foul smelling. The last period was March 18, 1919. April 14, while at work, she experienced a sharp pain in the region of the rectum, became dizzy, felt her heart pounding furiously and everything before her eyes turned black. She did not, however, lose consciousness. This was about 2:30 p. m. She was taken home and I saw her at 5 p. m. the same day.

Examination.—A young, well-nourished woman was lying in bed complaining of cramps and slight nausea. There was a slight pallor about the face. The temperature was 98.4; pulse 90 and of good quality. Because of the thickness of the abdominal wall and the extreme irritability of the patient, a satisfactory abdominal examination could not be made. However, there was no marked tenderness or rigidity. Vaginal examination disclosed a firm cervix with lateral lacerations. No tenderness or bulging in the vaginal fornices could be detected. The uterus could not be distinctly outlined. From the history obtained and the symptoms present, I advised her to enter the hospital, where an examination under ether could be made and the course to be taken decided on.

April 14, the patient entered the Wesley Memorial Hospital. April 15, the patient having been prepared for operation and anesthetized, bimanual examination showed the uterus slightly enlarged and freely movable. No masses were present at either side of the uterus. A uterine probe introduced into the uterine cavity encountered no resistance and slipped in up to the handle. A diagnosis of uterine perforation was made.

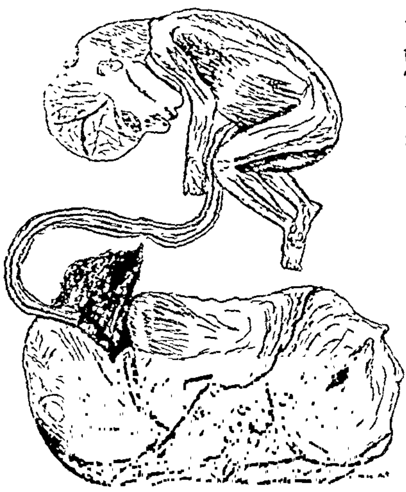
Operation.—A median incision was made from below the umbilicus to the symphysis, and on opening the peritoneal cavity, the entire area was filled with dark blood-clots. After removal of a large amount of clots and sponging out a quantity of dark fluid, the examining hand brought up a fetus from among the small bowels. From the development and size, the fetus was about five months old. The cord extended from the fetus to the uterus. The woman was placed in the Trendelenberg position and the uterus brought to view. A most interesting condition presented. The uterus was only slightly larger than the nonpregnant multiparous uterus, firm in consistency and at the fundus was attached a smooth, necrotic mass, the size of a small orange. There was a transverse tear at the junction of this mass with the fundus anteriorly. Protruding from this opening were tissues which were easily recognized as the placenta and its membranes, and into this opening extended the umbilical cord to its attachment.

Examination of the tubes and ovaries showed these structures normal. A supravaginal hysterectomy was decided on. The uterus was removed but the tubes and ovaries were left in situ. The cervical stump was covered with peritoneum and the two broad ligaments were sewed together, forming a broad firm support for the cervical stump and the vaginal vault. The abdomen was closed without drainage. On leaving the operating room the patient's pulse was 160. The foot of the bed was elevated and physiologic sodium chlorid solution was given per rectum, with the result that a few hours later the pulse was 100. By the fourth day the pulse returned to normal and remained so. There was an elevation of temperature for the first few days, the maximum reached being 101. The course from the fourth day on was uneventful and the woman left the hospital, April 28, thirteen days after the operation, feeling perfectly well.

Further examination of the specimen revealed a small perforation which connected the uterine cavity with the overlying necrotic mass. The perforation was a little to the right of the median line of the fundus. The mass over the fundus was friable and appeared to be organized fibrin and blood. This was completely filled with placental tissue. The placenta extended over the margin of the perforation and was attached for a short distance to the endometrium. Except for the point of perforation, there was a firm muscular wall between the uterine cavity and the placental mass on the fundus. The capacity of the uterine cavity was about two drams.

COMMENT

In view of the history obtained and the condition found at operation, what probably occurred was as follows: At about four weeks' pregnancy the catheters introduced either perforated the fundus or caused a local necrosis followed by perforation, with the expulsion of the products of conception into the peritoneal cavity. A portion of the placenta, sufficient to keep the fetus viable, retained its attachment to the endometrium. The rest protruded from the perforation and by partially filling up this opening no doubt controlled to some extent the hemorrhage which must have taken place, and so saved the woman from death from internal hemorrhage. However, there must have been a slow, continuous bleeding for the large amount of blood found in the peritoneal cavity and the absence of any severe shock would so indicate.



Uterus, placental mass and fetus.

The fetus and the greater part of the placenta lying extra-uterine became, in time, covered by a fibrinous deposit, which formed the false sac found at operation. The day preceding the operation this sac ruptured, giving rise to the symptoms then complained of and expelled the fetus into the peritoneal cavity. The size of the uterine cavity as compared with the size of the fetus definitely shows that for a period of about four months the fetus remained viable in the peritoneal cavity.

A careful search of the literature reveals only two cases of this type. Henrotin[1] reports a case in which perforation occurred at two months and in which operation was done a month and a half later. In this case the fetus contained in the sac was extra-uterine but the placenta was wholly within the uterine cavity. Leopold[2] reported a case from his clinic in which rupture of the uterus took place in the fourth month as result of a fall and pregnancy continued to term in the peritoneal cavity. Perforations in the course of a curettage or in attempted criminal abortions are not infrequent. No doubt some remain unrecognized.

Aside from the very unusual complication which I have reported, the literature abounds with reports of complications such as: prolapse of bowel through perforation, internal hemorrhage, peritonitis, sepsis, uterovesical and uterorectal fistula. Rupture of the uterus during labor is also encountered, especially through the scar of a previous cesarean operation.

In the vast majority of cases the symptoms are so prominent as to be recognized at once, and it has been estimated that in all cases, treated by operation and expectantly, there is a mortality of approximately 25 per cent.

30 North Michigan Boulevard.

AN EXTRACARDIAL MURMUR OF UNUSUAL ORIGIN

HAROLD FEIL, M.D. (Cleveland, Ohio)
First Lieutenant, M. C., U. S. Army
CAMP DIX, WRIGHTSTOWN, N. J.

Extracardial murmurs, in cases of chest injury, are sufficiently uncommon to warrant the report of the case of Private A. F., returned from overseas for discharge. A search in the literature has failed to reveal similar observations, although doubtless there may have been many, since Col. Warfield T. Longcope, in a personal communication, writes that he "heard of several while abroad."

Private A. F. suffered a shrapnel wound in the left chest posteriorly, Sept. 24, 1918, at Verdun. The piece of shrapnel entered the chest just below the angle of the left scapula. He was taken to a hospital, where bloody fluid was aspirated from the left chest, and on removal to a second hospital, Sept. 29, 1918, another aspiration was made; the patient was then evacuated to a third hospital, October 12, where the following note was recorded: "Left hemothorax filling almost entire cavity; heart markedly displaced to right; foreign body under left clavicle." October 21, "a portion of the sixth rib was resected in the axilla; the pleura was opened, bloody fluid drained out; adhesions were found all about the lung; a very heavy one above and behind. These were freed and the lung expanded well; the rib sutured in place; incision closed." A small piece of shrapnel was removed at this operation. October 31, the stitches were removed and the wound was found healed. It was noted that the lung expanded well and that there was still some fluid in the left chest. November 9, the left chest was aspirated and a few cubic centimeters of bloody fluid were removed. The lung expanded well; it was noted that a partial pneumothorax was present. November 16, the patient was classified "D" and then returned to the United States.

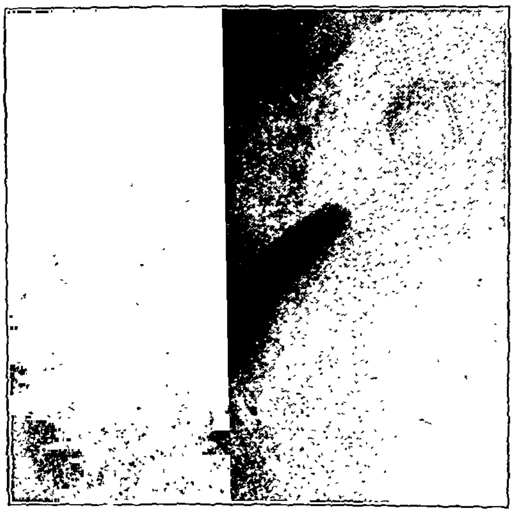

Fig. 1.—Anterior-posterior view of the chest: The foreign body can be seen just above the upper border of the third rib near the sternal line.

REPORT OF CASE

History.—The father, mother, two brothers, and one sister were living and well. No cancer or tuberculosis was present in the family. The patient had previously enjoyed good health. There had been no discomfort on exertion, and in the numerous physical examinations made before and during training, no cardiac abnormality had been noted. The patient walked into the hospital, apparently in normal health and without any complaint.

Physical Examination.—The patient was a well developed and well nourished man of 26, walking and exercising without fatigue or dyspnea. His pulse rate was 80 in the dorsal position—regular, rhythmic and equal. The left chest was somewhat less full, and the left costal border lagged. Three scars were visible—the first just below the angle of the left scapula, 2 cm. long; the second just above the outer third of the left clavicle, 1 cm. long, barely visible; the third, an operative scar, followed the left fifth rib from the midaxillary to the mammillary line. The fremitus over the left chest laterally and posteriorly was less than on the right side; the percussion note over the left chest in the axilla and below the scapula was impaired. The breath sounds were somewhat distant over the left back, but no evidences of moisture were found. The physical signs were believed to be those of a moderately thickened pleura.

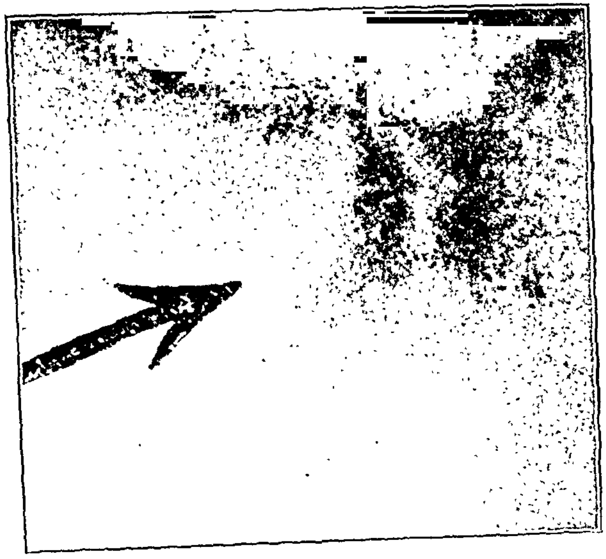

Fig. 2.—Lateral view of the chest: The fragment can be seen at the level of the fifth thoracic vertebra, just to the left of the body, near the pedicle.

Heart: The point of maximum impulse was in the fifth interspace, 8.5 cm. to the left of the midsternal line. The cardiac borders were as follows: The right cardiac border was 2.5 cm. from the midsternal line at the second, third, fourth and fifth costal interspaces; the left cardiac border was 2 cm. from the midsternal line at the second costal interspace, 6 cm. at the third, 8.5 cm. at the fourth and 8.5 cm. at the fifth interspace. The heart sounds were normal; a loud murmur, metallic in quality, was heard best over the third rib 6 cm. to the left of the midsternal line. This murmur, like the sound produced by the striking of cymbals, began in systole and faded away in diastole. It had one point of maximum intensity, although it could be heard over the entire left chest anteriorly and laterally. The murmur was heard faintly in the back, but was not transmitted to the vessels of the neck. It was equally intense in the various bodily positions, but when the arms were elevated vertically it faded out, and as gradually reappeared when the arms were lowered. This disappearance and the recurrence were noted on several examinations. Respiration did not change its character, but exercise intensified it. The reaction to exercise was within normal limits; the pulse rate dorsal was 80; standing, 80; after 100 hops, 100; two minutes later, 72.

Roentgenographic Report: "Metallic body about 2.5 cm. long and 0.5 cm. wide, apparently a shrapnel fragment, lodged in the chest at the level of the fifth thoracic vertebra, just to the left of the body near the origin of the pedicle." (R. Shoemaker 3d, First Lieut., M. C.)

COMMENT

An extracardiac murmur was evident in this case of chest injury caused by shrapnel. The murmur was dependent on cardiac systole and independent of respiration. It was distinctly separate from the cardiac sounds. It was not affected by change of bodily position except on elevating the arms, when the murmur faded out, to reappear on lowering them. The aorta rises to the level of the fourth thoracic vertebra, curving to the left of the fifth thoracic, so that the murmur may have been caused by the vibration of the scar tissue adjacent to the piece of shrapnel. Whether or not the murmur was due to the vibration of connective tissue with the foreign body acting as a sounding board could not be determined, but it may be definitely concluded that the murmur was a direct consequence of the chest injury, and that connective tissue played a distinct rôle in its causation. The act of raising the arms probably served to relax the strand of tissue, which was taut in other positions. Except for the unusual physical sign, the condition of Private A. F. was normal on discharge, and he has returned to civil life able to assume his prewar occupation.

THE ADVANTAGES OF THE VAGINAL ROUTE IN RESECTION OF THE RECTUM FOR CANCER

WILLIAM EDGAR DARNALL, A.M., M.D.
ATLANTIC CITY, N. J.

No attempt will be made here to enter into a full discussion of cancer of the rectum. That subject is too large for the scope of this paper. It is a well known fact that sufferers from cancer of the rectum may live a long time, much longer than those who suffer from cancer in almost any other part of the body. Cancer of the rectum offers more prognostic hope than does cancer in other locations. This is largely due to two factors: The type of cancer is usually adenocarcinoma, which is slow growing; and the region about the rectum is very scant in lymphatic supply, and therefore metastastis is slow and does not occur until the growth has encroached on other surrounding structures.

It is remarkable that cancer of the rectum may exist for so long a time without being discovered, and when discovered is found not to have involved surrounding tissues. Indeed many cases go on to a condition in which the rectum is completely blocked, and obstruction of the bowel takes place, before they are found, the symptoms being attributed to hemorrhoids or some other condition largely because no careful examination has been undertaken by the attendant.

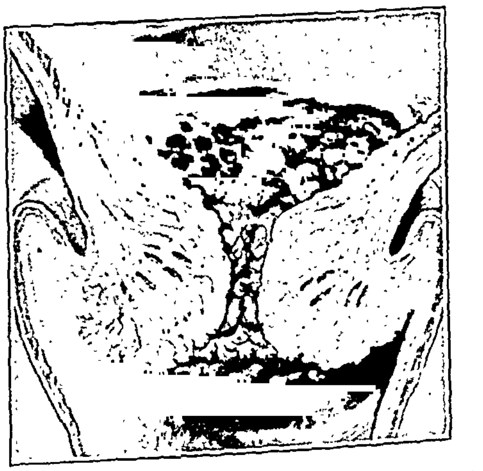

Fig. 1.—Rectum completely blocked by tumor.

Much has been written lately concerning the abdominal route, the sacral route and the combined abdominal route, inal and perineal routes. The old Kraske operation and others have been relegated to the junk heap, while the merits of the others and the question of a primary colostomy have been discussed at length; but I cannot find that much is said about the vaginal route in women, the simplest and easiest method of all.

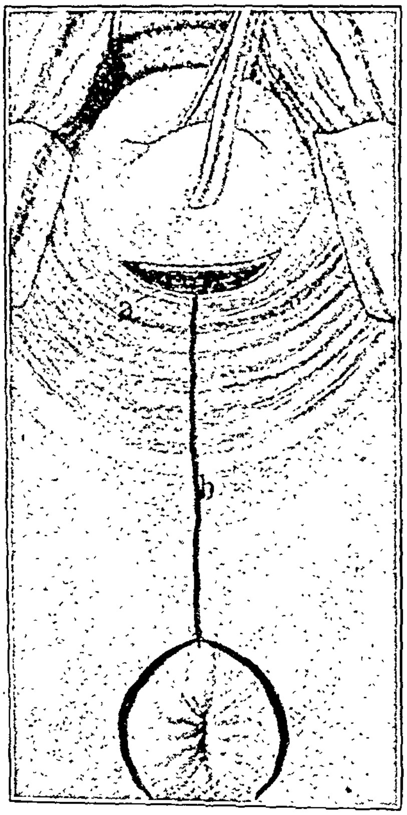

Fig. 2.—Long median incision from cervix to anus.

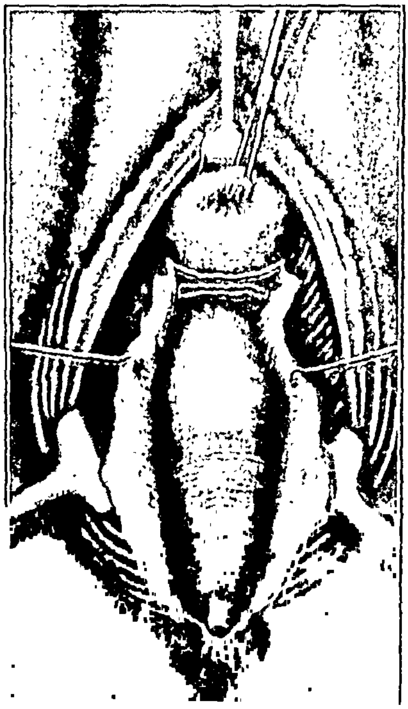

Fig. 3.—Vaginal flaps laid back exposing rectum (courtesy of Lea & Febiger).

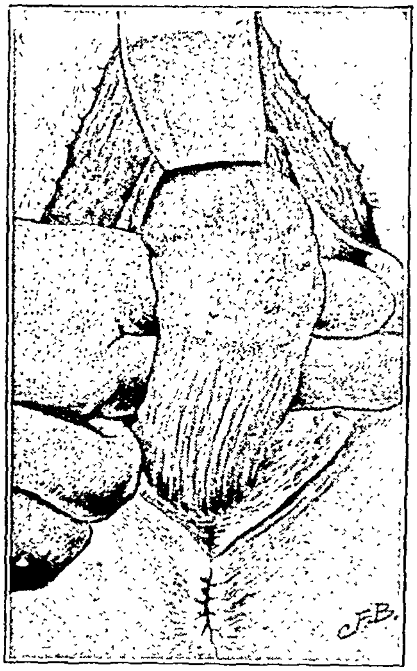

Fig. 4.—Rectum and growth lifted from its bed.

It is undoubtedly true that in the greater number of operations on the rectum for cancer the condition of the patient is much improved by a preliminary colostomy, just as happens in draining a bladder before doing a radical prostatectomy. Toxins are eliminated thereby, and opportunity is given for ulceration to be overcome. Inflammation is reduced, and an inoperable is often converted into an operable case. Intestinal obstruction is obviated if impending. The accompanying symptoms of pain, constant secretion and defecation are relieved, so that the patient may sleep and rest. Recuperation is thus insured, and the patient resumes her usual routine of life and is soon put into such a condition that she may successfully withstand the more radical major operation.

The technical advantages of the vaginal over the sacral route should be apparent to him who understands the anatomy of the pelvis. There are no important structures to be taken into account below the peritoneal fold except the two tubes which pass out through the levator ani muscle, namely, the vagina and the rectum. The operation consumes less time, there is less traumatism to the tissues, there is less hemorrhage and consequently less shock, which is an important factor in these weakened and toxic patients. There is no bone resection as in most perineal and sacral operations. I have always thought that the chiseling and sawing of bone in any operation must add materially to the shock of the operation. The dissection by the vaginal route is easy, the exposure is more perfect and one works in an open field rather than in the dark, thus being able completely to control hemorrhage.

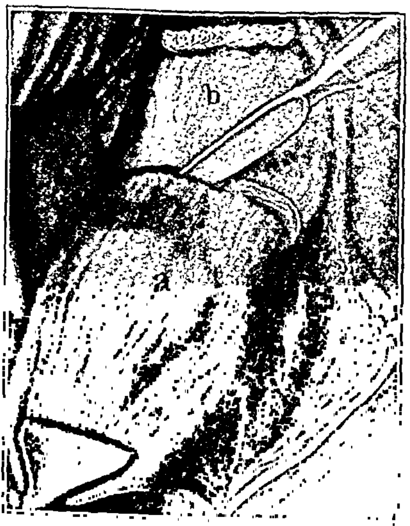

Fig. 5.—Resection of rectum (upper section should show clamp applied) (courtesy of W. B. Saunders Company).

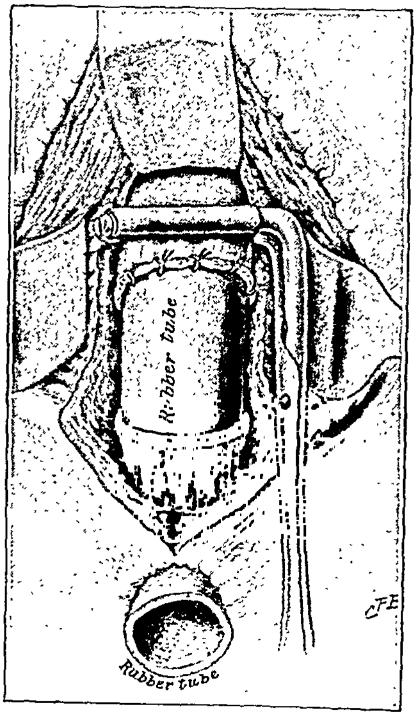

Fig. 6.—Tube sewed into upper segment emerging from anus.

Instead of being a *bête noir* of surgery, this operation for resection of the rectum for cancer resolves itself into little more than a complete dissection of the perineal structures for extensive vaginal repairs. The late John B. Murphy was an ardent advocate of this method of approach and did much to develop its technic. The operation is practicable only when the tumor is movable and is situated in the lower half of the rectum. If it is as high as the rectosigmoidal junction, then the combined abdominal and vaginal operation should be employed.

In beginning the operation, the sphincters should be thoroughly divulsed and the secretions of the rectum well washed away. A transverse incision is then made across the vagina at the junction of the mucous membrane of the posterior vaginal wall and the cervix. Perpendicular to this a median incision is carried down the whole length of the posterior vaginal wall over the perineum down to the anus. If the sphincters are to be retained, this incision should be deflected to each side at the anus. If not, it should continue completely around the margin of the anus. As the long median incision is deepened through the vagina and perineum down to the rectum, a large, thick flap of tissue is laid back on either side. This is made up of the muscular and ligamentous attachments of the vagina and rectum. When the rectum is reached, the fingers may be passed down along side of it and by blunt dissection the hand is passed, finally, completely behind it, lifting it out from its bed. It may then be easily pulled forward and it is remarkable how much of a loop of bowel may thus be pulled down. If it is rigid and there is difficulty in bringing it down, the simple expedient of nicking the posterior layer of the mesentery of the sigmoid at its lowest point just at the peritoneal fold will overcome the difficulty and allow it to come down freely.

The rectum is then clamped with a right angled, rubber tipped clamp about two inches above the margin of the growth and the rectum divided. If the sphincters are to be retained, the distal end of the rectum is similarly clamped and divided below the tumor. A 1 inch rubber tube is sewed into the upper end of the bowel and brought down and out through the anus, over which the anastomosis of the bowel is completed. After making the anastomosis it is well to draw the tubing down, slightly invaginating the upper into the lower bowel, and making a double row of sutures so as to assure perfect union and prevent leaks.

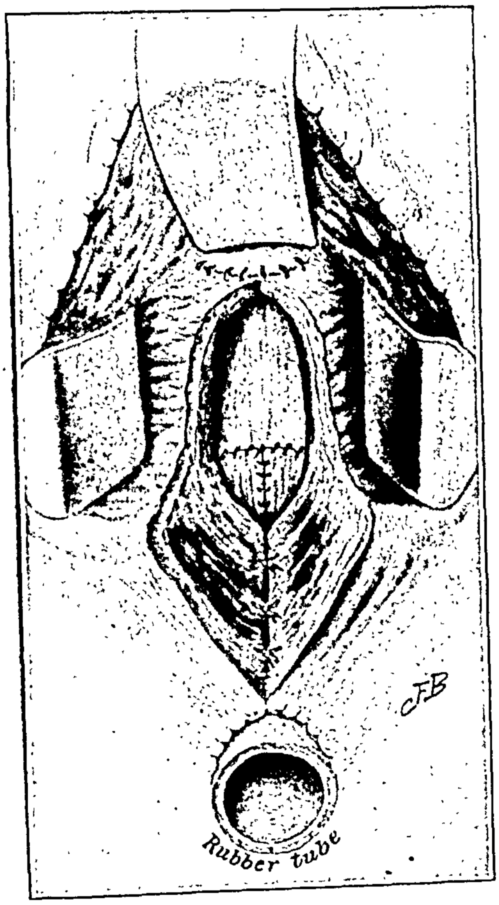

Fig. 7.—Anastomosis over tube completed.

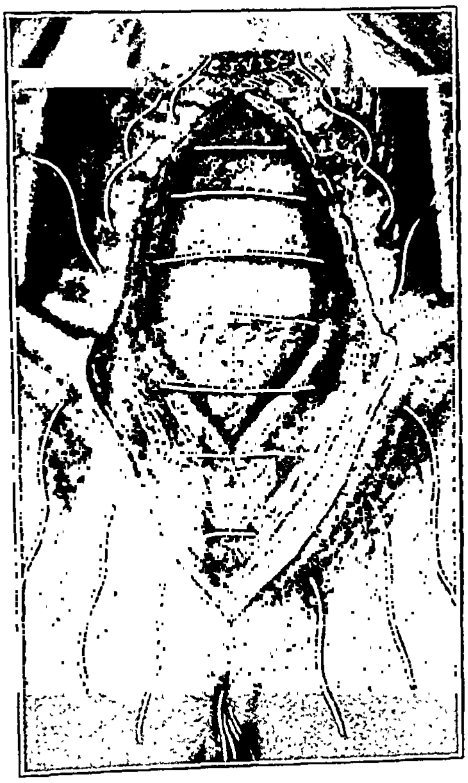

Fig. 8.—Sutures placed for vaginal and perineal repair (courtesy of W. B. Saunders Company).

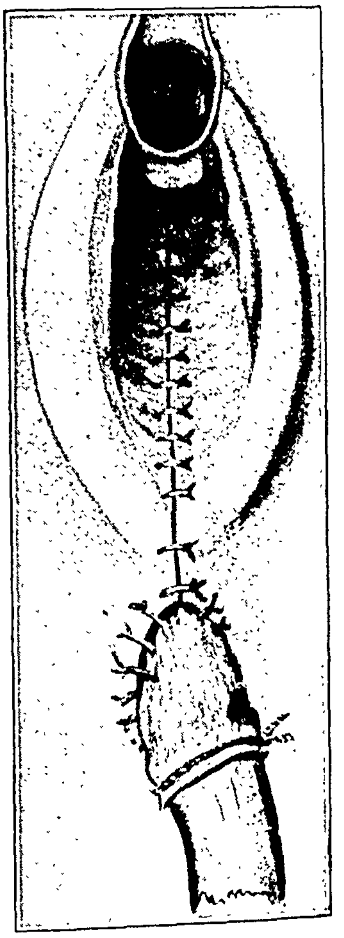

Fig. 9.—Vaginal excision of the rectum—the rectum sutured. A tube is tied into the divided end of the bowel.

In case the sphincters are removed with the rectum, the upper end of the bowel is brought out a full half inch or more beyond the anal skin and sewed fast to it. There is apt to be less stricture, perhaps, when the sphincters are removed than when they are not, but of course at the expense of fecal control. It is necessary to follow up the patient in these cases and keep the anus and bowel well dilated with rectal bougies as an after-treatment to prevent the formation of strictures.

After the rectal work has been completed, the muscles of the perineum are built up layer by layer, just as they would be in an extensive repair of the perineum, the lower lip of the cervix being sewed down to the transverse upper incision in the vagina.

Abdominal Symptoms Following Typhoid Inoculation.—Such symptoms were observed at Camp Custer in twenty-seven out of sixty-five admissions for typhoid reaction, and usually were not a cause of confusion in differential diagnosis from appendicitis. Typhoid inoculation did not appear to have played any demonstrable rôle as a cause of appendicitis or its recurrence. Typhoid inoculations have apparently resulted in recrudescence of old gallbladder disease; in a number of these there was a previous history of typhoid. In every case of abdominal pain, appendicitis should be considered, but attention to history and other symptoms and signs should usually result in avoidance of mistakes. A helpful thought in medicine is that reliance on any supposed pathognomonic sign, unsupported by other evidence, is dangerous.—*Review of War Surgery and Medicine* 2:28, 1919.

Clinical Notes, Suggestions, and New Instruments

ANEURYSM OF RIGHT VENTRICLE FOLLOWING TRAUMA: REPORT OF FATAL CASE

GEORGE H. CURFMAN, M.D., AND C. REX FULLER, M.D.,
SALIDA, COLO.

History.—N. H., aged 18, complained, July 19, 1917, of the effects of a kick in the epigastrium by a mule. Since the injury the patient had noticed difficulty in breathing, which had steadily increased in intensity. There was a persistent cough, accompanied by expectoration, the sputum consisting of frothy mucus, tinged with bright blood. The abdomen had become greatly enlarged during the previous month; likewise the ankles and legs. The personal and the family history were both negative.

Physical Examination.—The face was swollen, with marked puffiness under the eyes. The lips and the tongue were very cyanotic. The pulsation in the jugular veins was pronounced. On lying down the whole face became extremely cyanotic. The lungs were negative. The cardiac impulse was heaving in character and could be seen to extend from the seventh interspace about 1½ inches to the left of the nipple line over the entire cardiac area. The area of cardiac dulness was greatly increased both to the right of the sternum and to the left of the midclavicular line. Auscultation elicited a loud systolic murmur, which was most audible at the apex, and was transmitted over the entire cardiac area. At the end of systole this murmur became whistling in character, later fading into a faint blowing murmur. The second pulmonic sound was accentuated. The abdomen was distended with fluid and there was marked tenderness to pressure, most noticeable in the epigastrium. The liver extended about three finger breadths below the left costal margin and was tender to pressure. The lower extremities from the ankles to above the knees were swollen and edematous.

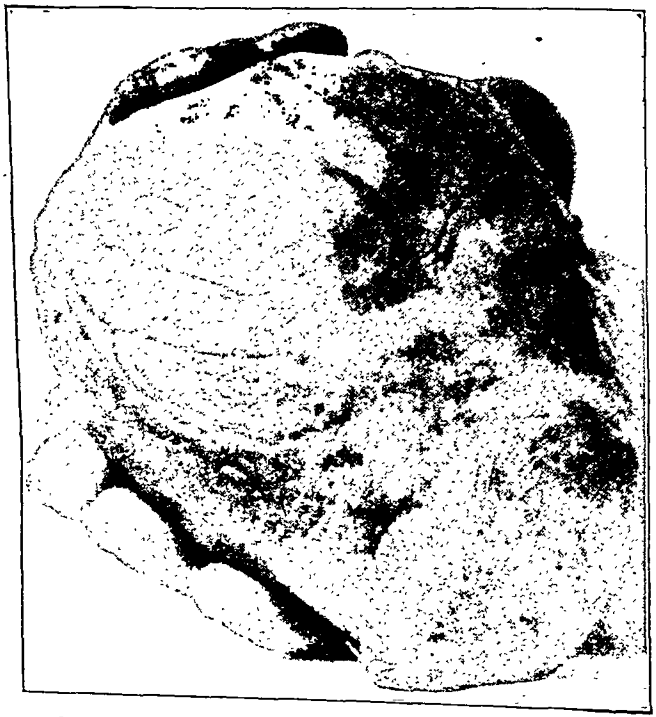

Fig. 1.—Anterior view of right ventricle showing aneurysm.

Clinical Course.—The patient gradually became worse; the cyanosis deepened, and the abdomen became steadily more distended with fluid. The pulse became irregular and weak, and, Feb. 27, 1918, the patient dropped into a mumbling delirium and died at 5:20 a. m., Feb. 28, 1918.

Necropsy.—On opening the chest wall the pericardial sac was found to be filled with about 1 liter of light, amber-colored fluid. The pericardium was greatly thickened. The lungs were normal. The heart was enlarged and weighed 723 gm. The circumference at the base of the ventricles was 13½ inches. The length of the right ventricle was 7 inches and of the left ventricle 5 inches. At the apex of the right ventricle was found an irregular tumor about the size of a half lemon, which proved to be a sacculated aneurysm of the right ventricle, connected with the right ventricle by an opening large enough to admit the index finger. The right ventricle was greatly hypertrophied with a relative insufficiency of the tricuspid valve. The abdomen was normal except for a large amount of ascitic fluid.

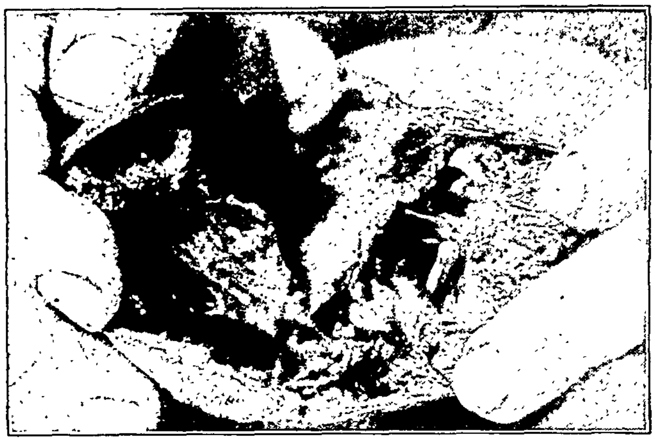

Fig. 2.—Aneurysm opened, the match showing opening into the right ventricle.

A CASE OF PROBABLE PATENT DUCTUS ARTERIOSUS IN AN ADULT *

CLEMENT H. ARNOLD, M.D., SAN FRANCISCO

The patient presented herself to me in February, 1919, with the complaint of dyspnea, always more or less marked, but latterly very severe on exertion; vertigo; loss of 20 pounds in three months; moderate loss of appetite, some slight gastric indisposition and palpitation.

HISTORY OF CASE

She stated that she was the wife of a retired military officer, whom she had accompanied on all of his official duties, having cooperated energetically in his affairs and social activities. She has been moderately athletic, has had a few minor attacks of rheumatism, but recently rather severe, precordial pains radiating high into the axilla, down the left arm and into the epigastrium. All her symptoms are negative in the anamnesis. There is one child living and well at 42; no subsequent pregnancies; catamenia at 50 with no disagreeable symptoms.

PHYSICAL EXAMINATION

The status praesens was that of a well preserved, slender woman of about 63, with dark vermilion lips, bluish mucosae, purplish red spots on the cheeks, slight bilateral epiphoria, red ears and markedly pulsating cervical vessels. The general appearance reminded one strikingly of chronic emphysema, coal-tar poisoning, advanced mitral stenosis, polycythemia and congenital heart lesions.

The eyes, ears, nose, mouth, teeth, throat and thyroid gland were normal. The thorax was slender, with a slight right scoliosis involving the upper thoracic vertebrae. There was a decided prominence over the upper precordium, implicating principally the first, second and third chondrosternal junctures. There was a rather more palpable than visible pulsation in the second left interspace one finger's breath from the left sternal line and there was a thrill practically coincident with systole in that area.

---

* Presented before the San Francisco County Medical Society, April 1, 1919.

Percussion of the chest, excepting the heart, showed no gross abnormalities, though there was some dulness at both bases with a few consonating râles that disappeared after cough; probably secondary to the cardiac condition.

Heart.—Palpation showed a forcible heave over the lower precordium of the choc en dôme type, with a thrill as noted above. Percussion revealed the following: The point of maximum intensity was at the fifth interspace, 9 cm from the midsternal line; retromanubrial dulness 3 cm. to the right and 7.5 cm. to the left; relative cardiac dulness 5.5 cm. to the right and 11.5 cm. to the left. Auscultation revealed a very irregular heart with what appeared to be interpolated ectopic beats. The first sound was loud and clear. At the apex the second sound was loud and metallic in character; there were no murmurs at the apex. The pulmonic second was very much louder than the aortic, having a note like the aortic bruit de tabourka found in hypertension. There were no murmurs except at the pulmonic area, where there was a moderately harsh "roaring" or "rumbling" murmur, which was accentuated at each systole. It was propagated out along the under side of the clavicle and lost at the deltoid sulcus.

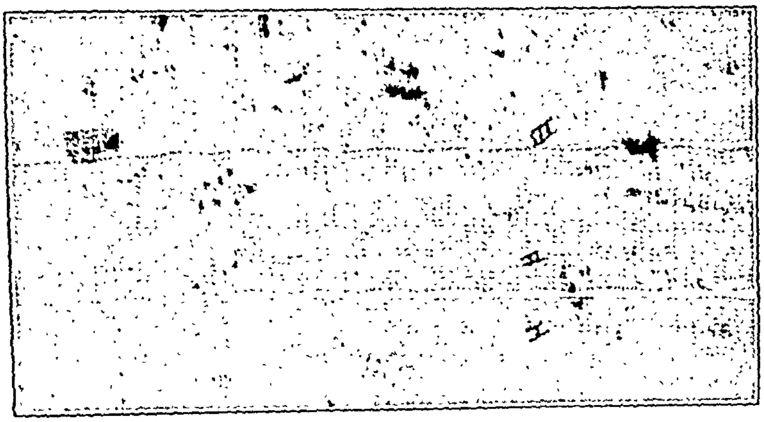

Fig. 1.—Electrocardiogram: Moderate irregularity of ventricles with no definite P waves. S is very marked in Lead 1, ventricular complex small in Lead 2, R highest in Lead 3. The conclusion was that there was hypertrophy of the right ventricle relative to the left, and that there was possible fibrillation.

The area of dulness indicated by the left lateral extension of the retromanubrial dulness joined the upper convexity of the relative cardiac dulness very steeply, demonstrating the so-called Gerhardt's area.

The reflexes were normal; the genitalia negative. There were no general glandular enlargements. The abdomen showed a moderate first degree of visceroptosis, with a right oblique inguinal hernia presenting through a wide-open ring with soft edges.

The pulse was normal in tone, very irregular and with a rate of 110; the vessels were not noticeably sclerosed. The blood pressure was 142 systolic and 80 diastolic. The patient weighed 115 pounds.

LABORATORY TESTS

The Wassermann was negative. The urine showed a slight trace of albumin. The phenolsulphonephthalein test resulted in an excretion of 32.5 per cent. in two hours. The stomach test meal showed 15 per cent. free acid, and 25 per cent. total acidity. Blood examination revealed red blood cells, 5,500,000; white blood cells, 8,700; hemoglobin, 95 per cent. The differential blood count revealed: polymorphonuclears, 49 per cent.; lymphocytes, 47 per cent., and transitionals, 4 per cent.

The electrocardiogram shows that the right ventricle as compared to the left is hypertrophied, and that fibrillation is probably present. Therefore it is evident ectopic beats may not be recognized when fibrillation is present; and if this is the case the statement made above is invalidated (Fig. 1).

The roentgenogram (Fig. 2) gives a most interesting picture. There is an increase in the transverse diameter of the heart shadow to right as well as left; probable dilated internal mammary artery (Fig. 2, 1), indicating increased collateral circulation; evidence of sclerosis, as there is (Fig. 2, 2) a definite crescentic plaque in the knob of the aorta. There is an increase in the transverse diameter of the mediastinal shadow, with marked prominence in the region of the pulmonary artery (Fig. 2, 3); there is a definite expansile pulsation of this prominence.

TREATMENT

It was observed that the initial bluish color of the mucosae and lips was greatly mitigated by rest, changing to a reddish pink. On the exhibition of digitalis the murmur at the pulmonic area became modified, growing louder and more continuous, and prolonged somewhat into the diastolic phase. As far as the heart is concerned the evidence caused the diagnosis of a probably patent ductus arteriosus, with a more or less surely accompanying patent foramen ovale.

COMMENT

The ductus arteriosus is the vessel which in fetal life connects the pulmonary artery with the aorta. It is usually about 10 to 15 mm. in length, and arises from the left branch of the pulmonary artery, joining the under side of the aortic arch just distal to the origin of the left subclavian artery, and represents the lateral vessel of the left sixth branchial arch. Its lumen usually becomes occluded a few months after birth.

One of the misconceptions that has prevailed is that the ductus in all adults is of insignificant size, but there are many cases in which, though it is by no means patent, examination reveals that it may be dilated to the size of a small lead pencil, and in the new-born may equal the main pulmonary trunk in circumference. Its existence with some of the attendant anomalies were known to Galen and Harvey, and since then many observations have been made as to its existence and persistence.

After the infant is born there very soon occur modifications of action and function in many parts of the body, the most extensive and spectacular being those of the circulation. It is, of course, well known that the ductus arteriosus serves to return from the right heart the unaerated blood from the head and upper extremities to the aorta and thence to the placenta. Since there is very little intrinsic circulatory activity in the pulmonary artery, owing to inactivity of the lungs, the pressure therein is relatively low.

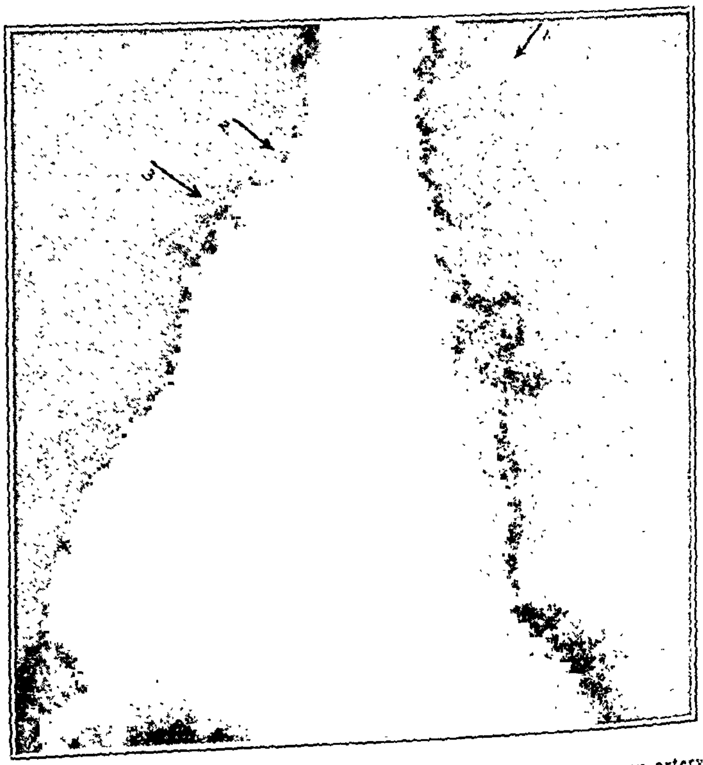

Fig. 2.—Roentgenogram of heart: *1*, dilated internal mammary artery evidence of sclerosis; *2*, crescentic plaque in the knob of the artery; *3*, prominence in region of pulmonary artery.

The opening of the ductus into the aorta is by means of a flap-valve-like arrangement, similar to that of the ureters into the bladder. As soon as the lungs begin to functionate and require a greater supply of blood with freer flow, the pressure falls, while that in the aorta becomes relatively higher. No blood, or very little blood, flows through the ductus and the flap of the valve is pressed down against the opposite wall of the ductus and occlusion is gradually effected; the lack of blood in the ductus depletes its vasa vasorum, fibrotic degeneration sets in and there is a pari passu contraction of the muscle tissue contained in its wall (Abbott).

When the ductus remains patent it is often associated with other defects in the structure of the heart, such as patent foramen ovale and interventricular septum.

Its exact pathogenesis under such a condition is, at best, obscure. Abbott says: "The causes of patency of the duct are to be sought in the conditions of its normal closure, and this must depend on the influences, mechanical or otherwise, of the changes in the circulation at birth, and on the action of the vessel wall, itself a fetal structure destined to involution."

It is probable, however, that "anything which causes obstruction to the flow of blood through the arch of the aorta in fetal life (aortic stenosis or atresia, congenital mitral stenosis, coarctation of the arch of the aorta, etc.) will cause the right ventricle to carry on the greater part of the circulation and force more blood through the ductus arteriosus. This condition, of course, persists at birth; the ductus, which now represents a main blood channel, remains open. The flow continues in the usual direction backward from the pulmonary artery into the aorta" (Hirschfelder). A narrowing of the pulmonary artery will reverse the flow.

As a primary and uncomplicated occurrence it is one of the rarest of cardiac anomalies, and the literature on the subject is correspondingly scanty.

The ductus may remain patent in a variety of forms which it is not necessary to enumerate here, by all odds the most interesting and the one giving the most signs and symptoms is that in which there succeeds an aneurysmal dilatation, with more or less involvement of the same nature in the pulmonary artery.

Most of these patients do not attain to adult life, though the condition is congruent with normal development during a long and useful career.

The most likely other forms of cardiac defect which it was deemed necessary to consider were patent foramen ovale, aneurysm of the sinuses of Valsalva, and pulmonary aneurysm. The first may certainly in this case be present, considering the frequency with which it accompanies a patent ductus; the second is not likely, as the signs are not present and there is nothing in the plate to indicate it; the last condition, if it does exist, is only a part of the whole, since its characteristic signs are not present, the dilatation is rather too high and too far laterally, and there is no evidence of pressure on the lungs within the mediastinum.

CONCLUSIONS

In conclusion, it will be interesting to compare the classical signs and symptoms given by the authorities on this subject (Osler, Abbott, Barker, Hirschfelder and Mackenzie), with those found in this case:

A proved case revealed the following conditions: (1) Gerhardt's area of dulness; (2) pulsating pulmonary artery; (3) dilated and hypertrophied right ventricle due to regurgitation into the pulmonary artery through the ductus; (4) dyspnea on exertion; (5) more or less cyanosis; (6) polycythemia may be present; (7) precordial bulging; (8) greatly accentuated pulmonic sound; (9) characteristic rough murmur with propagation out along clavicle; (10) Abbott says also that "arteriosclerotic patches are not uncommon in the neighborhood of the duct in the aorta . . . ."

By comparing this with what has been said about this case, it will be seen that all of the enumerated criteria were found. Besides, one may see that the arteriosclerotic patch mentioned in the tenth item is present in this patient (Fig. 2), and is remarkable as occurring in a woman with no other demonstrated sclerosis and a normal blood pressure for her age. For comparison, I should like to refer the reader to the plate shown by Hirschfelder,[1] illustrating a known case which is practically a duplicate of the one presented herein.

I am perfectly well aware that in such cases the only obiter dictum is necropsy, which can not be performed and which I hope will not for many years. But the findings were so clean-cut in this case and tallied so well with what is believed to indicate such a condition intra vitam, that I have deemed it worthy of record.

Under tincture of digitalis, 10 minims three times a day after meals, a general tonic and some light exercises serving to promote and maintain better respiration, the patient's heart has become more regular, the dyspnea on exertion has practically disappeared and she has gained 7 pounds in four weeks, while her general mental attitude is much more wholesome.

INSTRUMENT FOR HOLDING PERIPHERAL NERVES DURING SUTURE

W. Wayne Babcock, M.D., Fort McPherson, Atlanta, Ga.
Lieut.-Col. M. C., U. S. Army

The instrument for holding peripheral nerves during suture which is here described and illustrated has greatly facilitated the suture of divided nerves and has reduced, in some cases, the actual time of suture by one half.

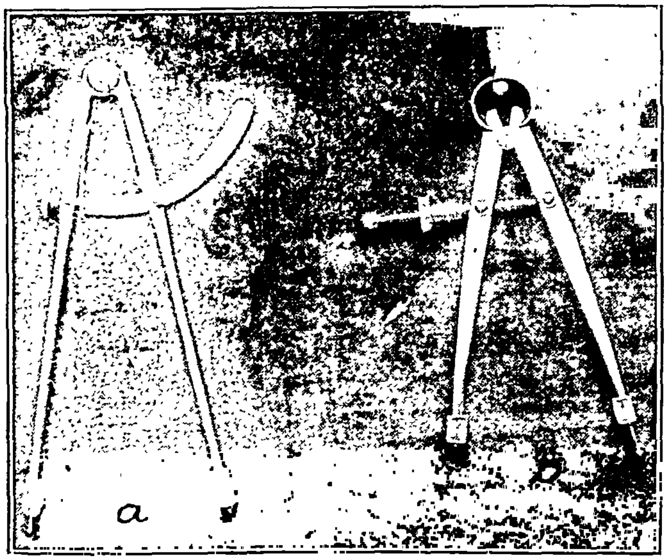

Fig. 1.—A, nerve clamp, showing glass headed pins used to fasten the nerve to the instrument. The milled screw to the left is a fine adjustment; B, insrument made from a pair of Starrett calipers, by brazing perforated curved ends and short pieces of small German-silver tubing (to receive the pins) to the arms of the instrument.

The halves of the instrument are applied and pinned to the nerve trunk 2 or 3 cm. distal to the proposed point of nerve resection. The nerve ends are then freed and sliced back by a razor blade until the section shows the desired fasciculi. By closing the arms of the instrument the nerve ends are apposed. After suturing the accessible edges of the nerve sheath, the instrument is turned over and the rest of the circumference of the sheath is sutured. The pins are now gently withdrawn and the instrument is removed. By applying the instrument before completely freeing and dividing the nerve, rotation and retraction of the nerve ends are prevented. After the instrument is applied, it should at once be tightened sufficiently to produce moderate traction. If there is a wide separation between the nerve ends, the continued tension will cause the nerve to stretch. The instrument may then be gently retightened from time to time as the operation proceeds, thus reducing the gap. The instrument should be made in at least two sizes. The grooves of the large instrument should be about 12 mm. and of the small instrument about 6 mm. in diameter. It may readily be made from a pair of Starrett calipers by brazing appropriate ends (Fig. 1 b). For the larger nerve trunk the small, glass-headed, steel pins of daily use serve very well. For very small nerves very fine needles to which metal or glass heads have been fused may be used. It is somewhat more convenient to introduce the needles from the shaft side of the instrument. We have had the instrument made also in the form of delicate hemostatic forceps with a long rachet adjustment. The instrument as illustrated in Figure 1 a has a thumb screw at the left which provides a fine adjustment.

---

[1] Hirschfelder: Diseases of the Heart and Aorta, J. B. Lippincott Company, Ed. 2, p. 543.

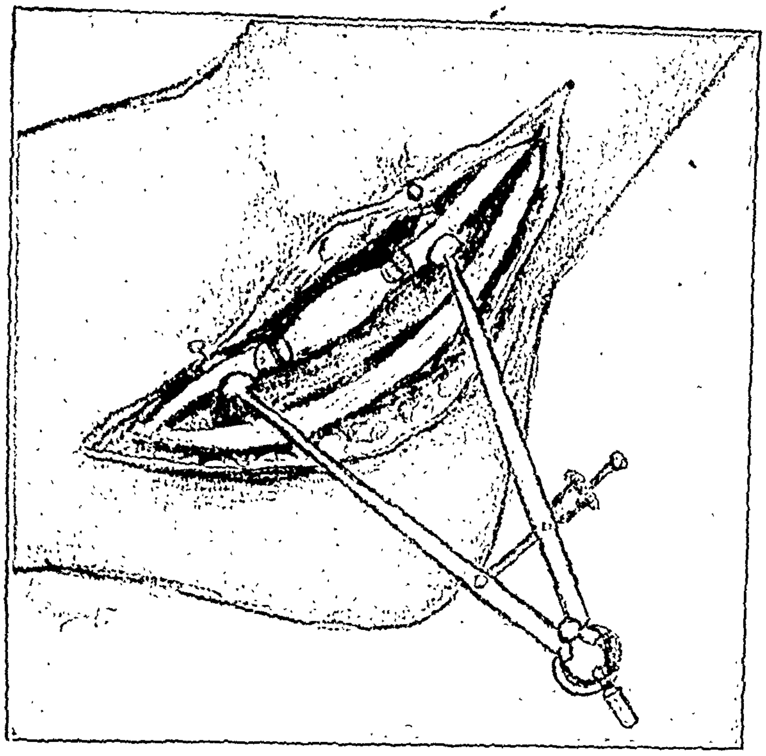

Fig. 2.—Nerve clamp pinned to posterior tibial nerve at the ankle, preparatory to resection of a neuroma in continuity. Repeated incisions are made into the neuroma until sufficiently normal sections of nerve trunk are found for end to end suture.

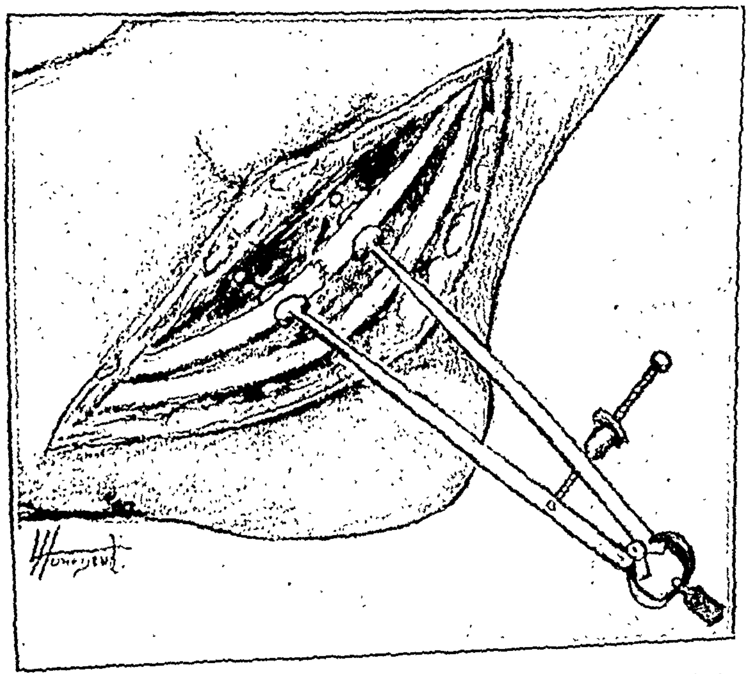

Fig. 3.—The neuroma has been freed and excised, the arms of the instrument brought together, permitting the nerve ends to be accurately united without tension by very fine black silk sutures which enter only the sheath of the nerve. The instrument obviates the need of the harmful transfixion or relaxating sutures through the nerve trunk.

If properly used the instrument should rarely tear out. It is believed that the reduction in the handling of the nerve outweighs the slight damage produced by small needle punctures. In over 100 cases of division of peripheral nerves from gunshot injury, we have found none in which an end to end suture could not be performed. For the larger nerve gaps, it is of course necessary to flex or extend the adjacent joints and perhaps also to dislocate the nerve to a new location. A number of gaps of 12 cm., of median, ulnar and sciatic nerves, have thus been overcome.

We are indebted to Major William G. Crumley, M. C., and to the Orthopedic Shop of this hospital for the preparation of working models.

Therapeutics

SUGAR IN THE URINE

The presence of sugar in the urine is a condition calling for investigation. While the occurrence may be accidental, or incidental to some indiscretion in diet, a decision must be made as to its cause. In many well persons sugar will readily appear in the urine if the normal starch and sugar ingestion is overstepped. These patients should be warned of their tolerance deficiency, and told that such intolerance may increase if they eat according to their desires. This narrow limit of tolerance may be inherited, or it may be caused by some glandular disturbance, or by previous disease that has left its mark on some organ concerned in sugar metabolism.

Excessive nervous or mental tire may be the cause of the sugar metabolic instability, or overmuscular activity, combined with some glycogen metabolism mistake, may cause sugar to appear in the urine. In other words, a patient found at times to have sugar in his urine should be studied, and then warned of the probable cause. A suitable, carefully modified diet should be arranged for him. His urine should be retested every few months.

GLYCOSURIA

The term "glycosuria" should not be used to cover up the possibility that more or less persistent excretion of sugar in the urine, even if readily prevented, is probably a mild diabetes or may be the forerunner of a severe diabetes. However, many patients with glycosuria have no other symptoms of diabetes, such as thirst, polyuria, dry skin, itching, loss of weight, and tendency to hyperacidity or to acidosis and its symptoms. In these cases, the pathologic condition is generally due to infection somewhere, or to glandular disturbance, also often caused by infection. Although in real diabetes boils readily occur from outside irritation and outside germs of infection, many boils and eruptions in both mild and severe diabetes are doubtless due to focal infection. Glycosuria may be caused by pyorrhea alveolaris, whether by such infection acting on the thyroid, the suprarenals, or the pancreas, cannot be determined; but many times glycosuria will disappear when the pyorrhea is eradicated, and these patients can again eat ordinary amounts of carbohydrates. It has long been recognized that thyroid and pituitary disturbances directly or indirectly may cause sugar to appear in the urine. Suprarenal disturbance may produce a glycosuria. Doubtless other focal infections, notably, perhaps, infection of the gallbladder, may cause glycosuria, or be the cause of real diabetes.

Some of these infection cases may be the ones that have shown improvement under ipecac (emetin) or under yeast treatment, while such treatment utterly fails in diabetes caused by other conditions. Even in these cases of mild diabetes, the blood pressure is generally very low, either from some insufficiency of the suprarenals or because the infection has also weakened the heart muscle.

The point it is desired to make in these cases is that every cause for the glycosuria should be sought. It is not sufficient to be satisfied with a regulation of the diet, even if such modification renders the urine sugar free.

DIABETES MELLITUS

1. As has been suggested, every possible cause should be sought and all side irritations and infections (if present) should be removed.

2. Inherited tendencies should be ascertained, both as to diabetes and to obesity.

3. The prognosis, even in childhood, is much better than it was before Allen clarified the diet treatment.

4. Loss of weight, even in the thin, need not be a matter for worry.

5. The amount of sugar lost per day on an ordinary diet and on ordinary exercise should be ascertained.

6. The presence or absence of diacetic acid and acetone bodies should be noted.

7. If the case seems a mild one, the starvation period may be taken with the patient up, but at home. If the case is severe, especially if there are signs of increased acidity, he must be in bed, as any muscular exercise adds to that acidity.

8. All fats should be excluded from the diet for several days before the starvation period is begun.

9. During the starvation period, the patient should receive plenty of water, with perhaps some clear tea or coffee. Mineral waters are of advantage.

10. Ordinarily the patient should be sugar free in forty-eight hours. If he is not, the starvation period may be prolonged another day or two.

11. If the heart is weak and coffee does not help it, strychnin, in doses of $^1/_{60}$ grain once in four hours, may be given, or digitalis may be given.

12. If diacetic acid, betaoxybutyric acid and acetone are dangerously increased in amount, whisky may be given, about one-half an ounce every three hours. Sodium bicarbonate is the most used treatment for this condition, and the dose must be large by the mouth; by the rectum in 10 per cent. solutions (perhaps by the Murphy drip method); and from 2 to 4 per cent. may be given, slowly, intravenously in physiologic sodium chlorid solution. If there is edema, which is a bad symptom, the alkali either should not be given, or given in small doses only. It has been suggested that perhaps it may be better not to give an alkali which may protect the dangerous ammonia from being used to neutralize the extra acid.

13. When the urine is sugar free, the use of foods containing a little starch should be begun to find the limit of tolerance; then small amounts of protein should be added, and later very small amounts of fat.

14. Diet tables for a gradual increase, especially of starch contained in vegetables, need not be given here, as they may be readily consulted elsewhere. Suffice it to say that the danger in a diabetic diet is the withdrawal of carbohydrates and the coincident allowance of too much fat. Sodium bicarbonate seems to help a diabetic properly to metabolize starch.

15. Constipation should be prevented.

16. There should be a fast day once a week. If the case is a mild one, this may be a green vegetable day, or an oatmeal day.

17. If these patients cannot take, or are not allowed to take, milk, some extra calcium should be given, perhaps as lime water.

18. Mild exercise is of advantage in diabetes; hard exercise is bad in severe diabetes, as it tends to precipitate an acidemia.

19. Even if the urine is sugar free, there may be a hyperglycemia. Also, acidosis may occur without diacetic acid in the urine. Hence the patient should be carefully studied, even with normal urine.

20. If a diabetic is to undergo an operation, fats should be excluded from the diet and starches should be reduced, but not absolutely removed; alkalis should be increased before the operation.

21. A diabetic woman becomes more acid during menstruation.

22. A diabetic should always dress warmly, and, if possible, he should go to a warm climate.

23. If a pregnant woman has a large amount of sugar in the urine which is not readily prevented by diet, consultation should be had as to the advisability of causing abortion or promoting premature labor.

Mental Defect in a Rural County.—That society pays a heavy penalty for the neglect of its children is emphasized by the results of a study made in an Eastern state by the Children's Bureau of the U. S. Department of Labor in collaboration with the U. S. Public Health Service. The conditions surrounding the 192 feebleminded children included in the study revealed the coincidence of poverty, drunkenness and delinquency with feeblemindedness. The county studied is a backward rural county, such as may be found in many sections of the United States. It boasts no town of more than 2,500 inhabitants. Bad roads and inadequate railroad facilities keep living conditions primitive. In a few homes spinning and weaving is still done on old-fashioned wheels and looms handed down from Revolutionary times. Whipping remains a punishment for larceny. School and church "socials" and yearly camp meetings are about the only recreational activities in the remoter districts. The 192 feebleminded children studied were between the ages of 6 and 20. Twenty-seven of them were so defective that they could not attend to their personal needs; sixty-five had serious physical handicaps; eighty-six were not receiving the care they should have. Only four children had been placed in an institution, unfortunately the county almshouse, which was not adapted to the care of such cases and had not the legal control necessary to insure proper protection. The parents of 54 per cent. of the white children and 71 per cent. of the colored children who were living in their own homes, were without the means to provide properly for their families. Although more than two fifths of the children from 12 to 20 years of age were capable of doing work under supervision and might have been helped by industrial training to perform higher grades of work, the county afforded them no opportunity for special training. The schools were inadequate for the needs of normal children. Most of them were of the one-room, one-teacher type, and many of them were so situated that numbers of children could claim exemption from attendance because of the distance to be traversed. The report suggests the possibility of providing training and supervision whereby certain types of mental defectives may safely remain in the community. The urgent need for institutional provision for those who cannot be given proper care in their own homes is emphasized.

NAUSEA AND VOMITING OF PREGNANCY

A group of symptoms affecting the pregnant woman and varying in severity from mild "morning sickness," through a range of more intense nausea, to the extreme of "pernicious vomiting" presents difficulties that are not always easy to combat. The theories advanced in explanation of the origin of these phenomena are unsatisfactory because most of these theories bear on symptoms that are at best only part of the possibilities presented by this particular type of nausea and vomiting. Acidosis, for example, which has been one of the explanations offered in the past, fails to account for the features observed in many instances. The hypothesis of "suboxidation" has not justified itself in attempting to explain these, as well as various other, pathologic disturbances. The hypothetic poison has not been discovered. The alleged accumulation in the blood of nonmetabolized nitrogenous compounds, such as amino-acids, has not been substantiated. As recent writers have summarized the situation: "Neither from the point of view of cause or cure has any satisfactory solution of the problem of nausea and vomiting or pernicious vomiting been arrived at. Rest in bed, forced fluids, attention to excreta, diet, and control of the nervous system by the use of mild and strong sedatives, appears to be the most commonly adopted procedure for this condition."[1]

There are various indications that point to the dominance of some metabolic factor in the origin of both the mild and the severer types of the nausea and vomiting of pregnancy. The symptoms appear most frequently in the morning after refraining from food for some time. Moreover, the common simultaneous occurrence of a ketonuria is an added indication of a metabolic upset. This symptom is usually observed when the supply of actually utilized carbohydrates is low, for example, when sugars fail to be oxidized, as in diabetes. Shortage of physiologically available carbohydrate, usually expressed in the glycogen supply of the tissues, frequently leads to infiltration of the liver with fats. Present-day physiologic evidence points to this phenomenon as an indication of carbohydrate starvation in the body. Fat is not deposited in the liver while carbohydrates are still available. In the liver, says Lusk, there is an antagonism between glycogen deposit following carbohydrate ingestion and fat deposition.

Mottram[2] has observed that in the pregnancy of ill-nourished animals, the liver may become overloaded with fat, just as is true in certain stages of inanition. In view of all these symptomatic similarities Duncan and Harding[1] of McGill University Faculty of Medicine, Montreal, have argued that these two factors, pregnancy and a short period of hunger, might account for the periodicity of morning sickness, and that the metabolic factor here concerned is a temporary relative lack of glycogen in the liver. Such a condition, they add, leads to a fatty infiltration of that organ.

The obvious practical conclusion that follows from this hypothesis is to preserve or enrich the supply of available carbohydrate for the patient. This is by no means a new procedure. Despite the current indifference to such a plan, the Canadian investigators have given renewed consideration to it. They have endeavored, in cases of varying severity of nausea and vomiting in pregnancy, to correct the assumed deficiency of carbohydrate supply by administering glucose or lactose, but mainly the latter, and they have supplemented this by a high carbohydrate diet. Duncan and Harding insist that psychologic advantages are not responsible for the good results which they have observed after such treatment. The gratifying report of success in more than seventy cases furnishes a justification for calling attention anew to what is at least a simple procedure in dietotherapy.

THE MODE OF ACTION OF MUSTARD GAS—DICHLORETHYLSULPHID

The veil of secrecy behind which many of the scientific investigations in relation to the prosecution of the war have necessarily and properly been conducted is gradually being lifted. Among the large number of startling items of information thus disclosed, few claim greater medical interest, particularly in respect to novelty and far-reaching significance, than do the war gases. The effects of chlorin attracted attention because this gas was the first to be employed, in the spring of 1915, in that hideous inhumanity known as gas warfare. The interest in chlorin and some of its later substitutes has been eclipsed by the consideration of the so-called mustard gas, dichlorethylsulphid, which had assumed a rôle of primary importance by the time the armistice was signed.

The distinctly local effects of mustard gas have been repeatedly described. They consist mainly of conjunctivitis and superficial necrosis of the cornea; hyperemia, edema, and later necrosis of the skin, leading to a skin lesion of great chronicity; and congestion, and necrosis of the epithelial lining of the trachea and bronchi.

---

[1] Duncan, J. W., and Harding, V. J.: A Report on the Effect of High Carbohydrate Feeding on the Nausea and Vomiting of Pregnancy, Canad. M. A. J. 8: 1053 (Dec.) 1918.

[2] Mottram, V. H.: J. Physiol. 38: 281, 1909; 40: 23, 1914.

These localized effects, severe though they may be, have not always seemed to suffice to account for the symptoms that sometimes attend intoxication with mustard gas. Such phenomena as vomiting and diarrhea, hyperexcitability and convulsions, and irregularities of the heart, observed in animals exposed to the deadly vapors, suggest the presence of systemic effects that are due to absorption of the poison into the blood stream and its distribution throughout the organism. This point of view is substantiated by the investigations of E. K. Marshall[1] and his colleagues in the Pharmacologic Research Section of the Medical Division of the Chemical Warfare Service, U. S. Army. Dichlorethylsulphid appears to be excreted in the urine, in part at least, as dihydroxyethylsulphid, a compound devoid of chlorin and shown to be comparatively nontoxic. The lesions of the intestine suggest that excretion of the substance may also take place there.

An outstanding fact about mustard gas is its progressive hydrolysis in aqueous solution whereby it breaks down rapidly to yield hydrochloric acid and residual compounds of low toxicity. Marshall and his associates have therefore attempted to correlate the toxicity of dichlorethylsulphid with the liberated hydrochloric acid. They picture the sequence of events as follows: Dichlorethylsulphid is very slightly soluble in water and very freely soluble in organic solvents, or has a high lipoid solubility or partition coefficient. It would, therefore, be expected to penetrate cells very readily. Its rapid powers of penetration are practically proved by its effects on the skin. Having penetrated within the living cell, it would undoubtedly hydrolyze. The liberation of free hydrochloric acid within the cell would produce serious effects and might account for the actions of dichlorethylsulphid.

Observations made on lower forms of animals likewise favor this hypothesis. Even though the undecomposed "mustard gas" is only slightly soluble in water, its peculiar lipoid-soluble properties enable it to penetrate into cells and presumably collect in relatively high concentration in the cell lipoids and fats of the protoplasm. In this situation, Clowes, Lillie and Chambers[2] remark, the substance serves as a reservoir of toxic material which continually enters solution in the aqueous phases of the protoplasm and is continually being decomposed there. Since, by its hydrolytic decomposition, it yields acid, the dissolved "mustard" acts destructively on the protoplasm as soon as the available buffer compounds (which normally prevent protoplasmic hyperacidity) are exhausted. The destructive action is thus due primarily to the hydrochloric acid freed by hydrolysis. The theory of the intracellular liberation of hydrochloric acid as the mechanism of action is consistent with the known facts of the pathology of mustard gas. Its skin lesion resembles hydrochloric acid burns. Many of the war gases can readily yield an acid by hydrolysis. The toxicity of dimethylsulphate may thus be due to an intracellular liberation of sulphuric acid. The ideal mode of treatment would seem to lie in the use of a basic substance having solubilities and penetrating power like that of mustard gas, but yielding a base on hydrolysis so as to neutralize the acid formed by the war gas. Fortunately, there is no longer need for haste in the search for a perfect antidote of this sort.

OXIDATION IN THE BODY

The answer to the question as to how the all important oxidations in the body are brought about is almost as obscure today as it was a hundred years ago when this mode of energy transformation in the animal organism was first being discussed. Not long ago, in touching on this perplexing subject, reference was made to the view, recently championed by several physiologists, that an enzyme (catalase) having the property of liberating oxygen from peroxids is principally responsible for oxidation in the body.[1] The justification for this contention has been derived essentially from comparisons of the catalase content of the blood in conditions differing essentially in the extent of the oxidative changes that may be assumed to be associated with them. For example, food and exercise promote oxidative metabolism in the organism; the catalase content of the blood was reported to be correspondingly augmented. The association of cause and effect is a mode of reasoning by analogy—always a somewhat doubtful procedure in science; hence the following comment in THE JOURNAL:

> There is a tendency to quote such statements without a due recognition of the limitations to our knowledge contained in them. It is one thing to observe the liberation of oxygen from peroxid in a test tube under the influence of a tissue extract or fluid; quite another problem is concerned in connecting such experimental facts with the complexities of reaction demanded by the known conditions of tissue oxidation. The mechanism of the latter remains, now as before, obscure and a subject for explanation.

In his latest contribution to this subject, Burge,[2] of the University of Illinois, the foremost advocate of the hypothesis that "the increase in oxidation produced by the ingestion of food as in other ways is due to an increase in catalase," has cited further physiologic parallelisms in support of it. In various communications regarding what they term the metabolic gradient underlying intestinal peristalsis, Alvarez and Starkweather,[3] of the University of California, have offered evidence that the catalase content of muscle and of mucous membrane per unit of weight is found to be graded from duodenum to ileum. Here again we can behold an instance of a striking parallelism between muscular performance, rhythmicity and irritability on the one hand, and the presence of catalase on the other.

[2] Burge, W. E.: The Reason for the Specific Dynamic Action of Protein, Am. J. Physiol. **48**: 133 (March) 1919.

The California investigators actually mention their data as "proof" for the view that the catalase content of a tissue is an index to its metabolic activity. It would assuredly be a fortunate circumstance to possess a suitable method for estimating with great accuracy the oxidative capacity of an organ or tissue in some simpler way than that now afforded by the measurement of respiratory or gaseous exchange. However, accuracy and dependability are a primary desideratum in any procedure of this sort. It is from this standpoint, rather than because of the obscure theoretical basis of the assertion that catalytic power is a measure of the metabolic activity of a tissue, that Becht,[4] of the Department of Pharmacology at the Northwestern University, Chicago, has attacked the thesis. He insists, on the basis of his own experimental researches, that no method has yet been devised which adequately measures the catalytic power of a solid organ. Becht has observed 1,000 per cent. variations in the bloods of different animals under identical conditions, and wide variations in the bloods of animals of different species.

With respect to the effect of thyroid feeding which unquestionably profoundly affects the metabolic performances of the organism, the different observers are by no means in accord. In contrast to Burge,[5] Becht maintains that there is a reduction in the catalytic power of blood during thyroid feeding; this is true not only for the whole blood but for each corpuscle also. Thus, he says, increased catalytic power of the blood cannot explain the loss of flesh during thyroid feeding, either because of the increased oxidation of material in the blood stream, or because of increased loss of catalase to the blood by the tissues, resulting in overactivity of the autolytic ferments, normally held in check by catalase.

Since the catalytic power of the blood varies between such enormously wide limits, from 100 per cent. to 1,000 per cent. in animals of the same species under the same conditions, Becht concludes that the catalases cannot be particularly important, and he does not believe that a study of catalases can possibly explain the mysteries of the processes of oxidation. Wherefore we may reiterate our earlier comment[1] that the mechanism of oxidation remains, now as before, obscure and a subject for explanation.

Current Comment

THE PREFERABLE LOW-CALORY DIETS FOR DIABETICS

In calling attention to the voluminous contributions to our knowledge of the intermediary metabolism of proteins, fats and carbohydrates which have been made in the study of diabetes, Graham Lusk has remarked that the work done is prophetic of possible accomplishment along scientific lines in the study of disease. "It is typical," he adds, "of that 'scientific medicine' which affrights the spirits devoted to a passing empiricism." Enlightened by the newer progress, the chemical pathologist has begun to see in the more severe forms of diabetes not only an incapacity of the organism to care for sugar in the normal fashion but also a more or less pronounced inability to metabolize properly the other foodstuffs that are essential to nutrition. Thus, to quote Lusk again, in the worst picture of the perverted metabolism of diabetes, sugar cannot burn, fat burns only as far as beta-oxybutyric acid; and as for protein, a part of the amino-acids are converted into sugar and another part into beta-oxybutyric acid, neither of which can be burned. For many years fat was the one unrestricted food of diabetics. Some clinicians pushed its use to the limit of endurance in order to keep up the weight of the diabetic patient. It is now understood, however, that liberal ingestion of fat may create or increase ketonuria in both normal and diabetic persons. Although persons may develop a capacity to live on a protein-fat diet free from carbohydrate, the danger of overtaxing the assimilative powers of an organism subjected to it are beginning to be recognized. F. M. Allen,[1] in particular, has given prominence to the menace of overfeeding with fat or of obesity for the diabetic. Allen has succeeding in imitating in dogs the appearance of the spontaneous downward progress observed in human patients. From elaborate studies on both man and animals, he believes it to be conclusively demonstrated that the attempt at high nutrition, even with fat, produces in these dogs an appearance of spontaneous aggravation of condition as striking as anything witnessed in human patients, and that this result can be prevented, at least for periods of years, by limiting the total caloric intake and the body mass to correspond to the assimilative function. The experience with diabetic dogs warns unmistakably against efforts to maintain patients on a luxus level of diet or weight. As Allen says, restriction of single foods, as carbohydrate or protein, suppresses symptoms temporarily; but lightening the total load on the weakened assimilative function is the only present means by which it may be hoped actually to halt the diabetic process. It has lately been argued by Mosenthal and Clausen[2] that probably the lowest diet that will conserve the physical and mental efficiency of the diabetic is that which maintains the nitrogen equilibrium of the patient.

[2] Mosenthal, H. O., and Clausen, S. W.: The Maintenance Diet in Diabetes Mellitus as Determined by the Nitrogen Equilibrium, Arch. Int. Med. **21**: 269 (Feb.) 1918.

This was alleged to be attainable on a carbohydrate-free diet by a food intake of from 1,500 to 2,000 calories, the variations usually depending on the size and the sex of the patient. No attempts were made to determine which of the ingredients of a starch-free dietary, fat, protein or alcohol, was the most efficient protein sparer. A more recent study of diabetic patients in the Medical Clinic of the Johns Hopkins Hospital by Mosenthal and Harrop[3] gives some intimation of the relative values at stake. The cases were only of moderate severity. The outcome, controlled by careful chemical examinations, shows that the addition of an equal number of calories of protein, fat or alcohol to a low-calory carbohydrate-free diet in cases of diabetes mellitus results in the assimilation of considerable amounts of nitrogen when the protein is used, a favorable nitrogen balance in only occasional instances with fat, and no change in the nitrogen equilibrium when alcohol is given. In the opinion of Mosenthal and Harrop, this would point to a high protein diet as the most advisable low-calory, carbohydrate-free diet by which to conserve the body tissues and furnish a maintenance ration for the diabetic.

THE EARLY HISTORY OF MEXICAN TYPHUS (TABARDILLO)

In the City of Mexico few persons are so well known among the scientific people as is Dr. Nicolás León, professor of physical anthropology in the National Museum of Archeology there. Through his visit to this country, some years ago, Dr. León became known to a few for his excellent work in anthropometry and medical history. His "History of Obstetrics in Mexico" down to the year 1910, a book of 740 pages, is a highly original work, based on his own researches and replete with interesting pictures from the Aztec hieroglyphs and the older Catholic publications. His recent papers on the history of Mexican medicine in the *Gáceta Médica de México* are scholarly and exhaustive. Mexico was a kind of pioneer in medicine in the New World. The first hospital in this hemisphere was built by Cortez in the City of Mexico in 1524; the first chair of medicine was established in the University of Mexico about 1578-1580 (The Journal, Oct. 10, 1908). Haller's bibliographies show that the first medical books to be printed in the New World were the "Opera Medicinalia" of Francisco Bravo (Mexico, 1570) and the "Summa y Recopilación de Cirugía" of Alphonso López (Mexico, 1578); the first medical periodical (Dr. León shows) was the "Mercurio Volante" (Mexico, Oct. 17, 1772). In spite of his age and of many losses sustained during the recent revolution, Dr. León has continued his excellent work, as shown by his interesting contribution[4] to the Congreso nacional del tabardillo (Mexico, Jan, 14-21, 1919) on the history of tabardillo or typhus fever which Humboldt, in his American Travels of 1799-1804, noted as existent in Mexico in 1576. Dr. León considers the etymologies of two Aztec words of the nahuatl idiom, viz., *matlazahuatl* and *cocoliztli.* Briefly *matlazahuatl* (*matlatl,* mesh, *zahuatl,* eruption) is the Aztec name for the tableland disease noted by Humboldt; *cocoliztli* (from *cocoa,* to be sick), also employed by the Aztecs as a synonym for tabardillo, would appear to be a general term for an epidemic or plague. Tabardillo (a little cloak) was the expression employed by the Spaniards for typhus as it appeared after the siege of Granada in 1489. The earlier Mexican accounts of tabardillo are to be found in the two books of Bravo (1570) and López (1578) mentioned above. Strange to say, there are no copies of either Bravo or López to be found in Mexico at the present time; both books are exceedingly rare. Another work in manuscript on the epidemic of tabardillo in 1576 by Francisco Hernández "De Morbo Novae Hispanae anni 1576, vocato ab Indiis Cocoliztli") was destroyed in the burning of the Escorial in 1671. Dr. León bases his findings on a medical treatise ("Tractado breve de Medicina") by Friar Agustín Farfán (Mexico, 1592). Here tabardillo is described as a continuous fever with an exanthem (*pintas*), the semeiology being an elaborated casuistry based on the old doctrine of the humors and the treatment "profuse and reiterated bloodletting," with a long list of vegetable remedies. Except in the title, the word *cocoliztli* is not found anywhere in this book. The many Mexican medical authors of subsequent date, cited by León, say substantially the same thing, with more or less prolixity, and nothing new is added prior to the treatises of Anacleto Rodríguez Argüelles (1811) and Luis Montaña (1813). Here the symptomatology is given in greater detail and the nature of the disease becomes more recognizable. The first Mexican epidemic of typhus, in historic time, occurred in the year 1519. Dr. León concludes with a graphic account of the sixth epidemic (1576) by an eye-witness (evidently from an old public document). The effect of the epidemic on the population of the Mexican capital is sensed in the reproduction which Dr. León gives of a painting by the artist P. Miranda, which is strongly suggestive of the illustrations of the horrors of yellow fever in some of our earlier American books.

ONE REASON SCIENTIFIC MEDICINE LAGS

It is a medical journal—so the cover declares—and according to the title page is "the Official Organ of the Mississippi Valley Medical Association, and the Ohio Valley Medical Association." It is said to circulate "among the most progressive physicians of the Middle West." The magazine is well printed, on a fair grade of paper and of neat, if not elaborate, typographic make-up. The advertising (other than that relating to the journal itself) occupies fourteen and one-half pages, or, omitting "reading notices," thirteen pages. More than three fourths of these pages are devoted to advertising proprietary medicines, twenty in all. Eighteen of these proprietaries have been the subject of adverse reports, fifteen by the Council on Pharmacy and Chemistry and three by The Journal. Incidentally, not one of the four articles—readable and worth while—that comprise the "Original Contribution" department is original. Each has been "lifted" from some other source. This, however, by the way, for good articles are a scarce commodity. Just what excuse can be offered for this publication in its present form—and similar publications, for it is but a type—it is difficult to see. It presumes to represent the medical profession, but its only apparent reason for being is as a medium for advertising products, the bulk of which disgrace medicine and degrade therapeutics. These facts are few but discouraging. They furnish at least one explanation — possibly more — for the lukewarm attitude of some manufacturers of proprietary remedies toward the work of the Council on Pharmacy and Chemistry.

DUODENAL DIABETES—AN EXPLODED FALLACY

The introduction of the expression "duodenal diabetes" into the literature of medicine is due to the late German physiologist Eduard Pflüger[1] of Bonn. Having observed that section of the intramesenteric nervous connections between the pancreas and duodenum in the frog may, under certain circumstances, give rise to a glycosuria, he called into question the existence of a pancreatic diabetes. Minkowski subsequently silenced this charge against what had been regarded as an established demonstration, by a successful experimental extirpation of the duodenum without producing a state of diabetes so long as a portion of pancreatic tissue was left intact in the body. Duodenectomy is, however, a dangerous procedure; and, since scarcely any cases of prolonged survival of the subjects are on record, the possibility that the duodenum is indispensable for physiologic wellbeing has remained to be definitely considered. Thanks to the ingenious operative procedure described by Moorhead and Landes in a recent issue of THE JOURNAL,[2] complete removal of the duodenum in consecutive operations is permitted. The jejunum is made to serve as a substitute for the duodenum and to receive the pancreatic and biliary secretions through transplanted ducts. The experiments made by the authors at the University of Chicago show that "dogs thus operated on will live in a normal state of health. The duodenum, therefore, is not essential to life." The outcome reminds us of the comment of von Fürth of Vienna on the subject of duodenal diabetes: "Strictly speaking, nothing at all has been gained in this whole campaign fought with an array of heavy artillery of authority and between strategists of note, except the reestablishment of a fact that has long been known—the influence of nervous irritations of all sorts causes the liver to discharge its supply of carbohydrate which sometimes gives rise to glycosuria."[3]

THE HEALTH OF THE ARMY

Statistics published this week in the "Medical Mobilization and the War" department show that the Medical Department of the Army established an enviable record during the war. The yardstick with which to measure the work of this department is the effective list, and the record shows that, on an average, 94.3 per cent. of our army were effective for duty; of the remaining 5.7 per cent., only 3.4 per cent. were on the noneffective list because of disease. The medical corps of an army is put to its hardest test when it follows the army into action. The total number of American soldiers wounded was 195,000, of whom the Medical Corps saved the lives of 182,000; of these there are but few who carry empty sleeves or use artificial legs. And so the figures go: a venereal disease rate lower than that of any of the Allied or enemy forces; typhoid fever practically eliminated, and a rate from even the dread scourge pneumonia that was less than might have been expected under the conditions.

Association News

THE ATLANTIC CITY SESSION

Information Regarding Hotels

Representatives of the Hotel Committee of the Atlantic City Committee of Arrangement will be at the railroad stations in Atlantic City where they may be consulted by Fellows and guests of the Association who have not made their hotel arrangements. Hotel information also will be available at the place of registration, Music Hall on the Steel Pier. The Local Committee of Arrangements gives assurance that there will be no difficulty whatever in securing comfortable hotel accommodations.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending May 31, there were 15,306 officers in the Medical Corps, a decrease of 491 from the previous week. The Medical Reserve Corps contained 1,961 officers. The total number of medical officers discharged since the beginning of the war is 17,024.

U. S. Army Found Healthiest in History of War

In a modest quarter of Tours in a house built in the 16th century are the sick and wounded records of the American Army—4,300,000 cards that show the health, the wounds, the diseases, the deaths and the recoveries in the American Army. Ninety-four and three-tenths per cent. of the Yank Army was effective for duty at all times, and of the 5.7 per cent. on the noneffective list, only 3.4 per cent. were so rendered by disease. Of the 195,000 Americans wounded, the Medical Corps saved the lives of 182,000.

To date there have been 72,723 deaths in the A. E. F., of which 32,392 were out on the "high field rendezvous," 13,420 of wounds and battle causes, 22,205 of diseases, and 4,806 of accidents and other causes. The venereal rate has been decidedly the lowest of any of the allied or enemy armies, varying from 57 to 34 a year for each thousand of its men, and averaging less than 40 as a whole. Typhoid, which used to be the great scourge of armies, played a very insignificant part in the battle between disease and the American army. There have been only about 1,000 cases altogether and less than half a hundred deaths. Pneumonia replaced it as the most dreaded of diseases. At the time of the armistice, there had been about 8,000 deaths from this disease and influenza in the A. E. F. Epidemic dysentery, although causing only a very few deaths, at one time pervaded our fighting forces to a serious extent.

[3] Von Fürth, Otto: The Problems of Physiological and Pathological Chemistry of Metabolism, translated by Allen J. Smith, Philadelphia, J. B. Lippincott Company, 1916, p. 251.

In the A. E. F. there were 15,690 officers, 8,587 nurses and 122,473 enlisted men of the Medical Corps; 153 base hospitals, 66 camp hospitals, and 12 convalescent camps. We had 193,000 beds on Nov. 11, 1918, capable of an emergency expansion to 276,000 in case of need. The program of procurement and construction would have assured us by this time of 423,700 beds and an emergency expansion of all kinds of edifices.

Mortality Statistics of the Army

The following figures as to deaths in the United States Army are not absolutely definite, but are subject to some corrections:

ALL TROOPS IN THE UNITED STATES SEPT. 1, 1917, TO MAY 2, 1919

Average strength 1,130,052

	Number of Deaths	Annual Rate per 1,000
All causes	34,729	18.369
External causes	1,552	0.821
Suicides	207	0.110
Other external causes	1,344	0.711
Wounds received in action	1	0.000
Disease only	33,177	17.548
Pneumonia	27,074	14.320
Meningitis	1,190	0.629
Typhoid fever	51	0.003
Tuberculosis	760	0.401
Dysentery	17	0.001
Measles	89	0.005
Scarlet fever	88	0.005
Empyema	361	0.191
Septicemia	172	0.091
Influenza	1,1877	0.627
Other diseases	2,188	1.157

AMERICAN EXPEDITIONARY FORCES, FRANCE, OCT. 18, 1917, TO MAY 2, 1919

Average strength 991,344

	Number of Deaths	Annual Rate per 1,000
All causes	62,205	40.78
External causes	45,970	30.14
Suicides	36	0.023
Wounds received in action	44,056	28.887
Other external causes	1,878	1.232
Disease only	16,235	10.64
Pneumonia	12,661	8.301
Meningitis	947	0.621
Typhoid fever	162	0.106
Tuberculosis	460	0.302
Dysentery	25	0.016
Measles	30	0.020
Scarlet fever	79	0.052
Empyema	136	0.089
Septicemia	112	0.074
Influenza	209	0.137
Other diseases	1,414	0.927

ALL TROOPS IN THE UNITED STATES, SEPT. 1, 1917, TO MAY 1, 1919, PLUS ALL TROOPS IN THE AMERICAN EXPEDITIONARY FORCES, FRANCE, OCT. 18, 1917, TO MAY 2, 1919

Average strength 2,121,396

	Number of Deaths	Annual Rate per 1,000
All causes	96,934	28.849
External causes	47,522	14.525
Wounds received in action	44,057	13.501
Suicides	243	0.007
Other external causes	3,222	0.955
Disease only	49,412	14.324
Pneumonia	39,735	11.509
Meningitis	2,137	0.625
Typhoid fever	213	0.064

To Fort Bayard, N. M., from Camp Dix, Capt. W. A. VEE CASH, Abilene.

To Fort Bliss, Texas, from Camp Bowie, Major H. CLARK, Crowell.

To Fort D. A. Russell, Wyo., as tuberculosis examiner, from Denver, Lieut. C. R. GOWEN, Carlsbad.

To Fort Sam Houston, Texas, from Camp Dix, Lieut. J. W. GOODE, San Antonio; from Camp Lee, Capt. L. E. McADON, San Antonio; from Camp Travis, Lieut. C. M. COVINGTON, Montgomery.

To Hoboken, N. J., from Newport News, Lieut. L. S. JOHNSON, Richmond.

To report to the commanding general, Southern Department, from Camp Bowie, Capt. D. C. WYLIE, Asperton.

Virginia

To Camp Lee Va., from Camp Dix, Major A. T. FINCH, Chase City.

To Eastview, N. Y., from Lakewood, Lieut. J. W. ROBERTSON, Onancock.

To Washington, D. C., Surgeon General's Office, from Philadelphia, Major J. W. H. POLLARD, Lexington.

Washington

The following orders have been revoked: *To Fort D. A. Russell, Wyo.,* from Camp Lewis, Lieut. H. J. HARDS, Tacoma. *To Fort Des Moines, Iowa,* from Camp Dix, Lieut. H. T. BUCKNER, Seattle.

Wisconsin

To Camp Grant, Ill., as tuberculosis examiner, from Camp Lewis, Lieut. L. F. RUSCHHAUPT, Milwaukee.

To Camp Meade, Md., from Dover, Capt. P. L. SCANLAN, Prairie du Chien.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Marriage Law in Effect.—The new law requiring all men seeking marriage licenses to undergo a physical examination within fifteen days before the issue of the license went into effect, April 21.

Hospital Items.—The Pike County Masonic Hospital has been incorporated at Troy with a capital stock of $40,000. A lot at Pine and Walnut Streets, donated by Fox Henderson & Sons, will be used for the site of the hospital.——The Fraternal Hospital, Birmingham, has been incorporated with a capital stock of $50,000.——At a special meeting of the Memorial Hospital Committee, Montgomery, held April 21, it was decided to raise $200,000 for the erection of a city hospital to be called the Montgomery Memorial Hospital. Of the amount needed, $85,000 has already been secured.

ARKANSAS

Personal.—Dr. Francis T. Isbell, Horatio, retiring president of the state board of medical examiners of the Arkansas Medical Society, was presented with a silver loving cup by the members of the board, May 14.——Dr. Charles A. Arkebauer, Little Rock, senior surgeon of the State Hospital for Nervous Diseases, Little Rock, has been appointed assistant superintendent, to succeed Dr. Roland F. Darnall, who has resigned.——Drs. James G. Townsend and Morgan Smith have been elected members of the board of health of Little Rock.——Dr. Aaron A. McKelvey, Fort Smith, has been elected district health officer by the district board of health.——Dr. Fred C. Rowell has been elected city physician of Pine Bluff.——Drs. William C. Russwurm and Aris W. Cox have been appointed members of the board of governors of the Helena Hospital.——Dr. Percy A. Riddler has been appointed a member of the Fort Smith District Board of Health.

CALIFORNIA

Tax Refund.—Senate Bill No. 405, introduced by Senator Sharkey of Martinez, has been passed by the legislature and signed by the governor. This act authorizes the stated board of medical examiners to refund taxes, fees and penalties collected by mistake, error, or inadvertence, and provides an appropriation therefor. The provisions of this bill become effective ninety days after the adjournment of the legislature. The attorney-general has rendered an opinion permitting the board of medical examiners to exempt from payment of the $2 annual tax thoses licentiates who gave their services to the national government during the recent war as commissioned medical officers in the U. S. Army, Navy or Public Health Service. Such licentiates are exempt from payment of this charge while in the discharge of their official duties. If a licentiate was connected with any of these services from January 1 of one year to January 1 of the succeeding year he is exempt from the tax, but in the event that during a portion of any year the licentiate was not so connected, he is liable for the tax. Proof of exemptions for tax or claims for refund will be sufficient if the licentiate forward to the board of medical examiners an affidavit containing a copy of his appointment and discharge, further substantiated by the statement of the exact date of service and termination thereof, with rank at date of discharge or the statement that he is still on active duty.

CONNECTICUT

Personal.—Leonard W. Bacon, Major, M. C., U. S. Army, New Haven, has recently been made chief of the orthopedic service of U. S. Army General Hospital No. 32, Chicago.

New County Society Officers.—Litchfield County Medical Association at its one hundred and fifty-fifth annual meeting held in Waterbury, April 23, elected Dr. Charles H. Turkington, Litchfield, president; Dr. Frederick William Wersebe, Washington, vice president, and reelected Dr. Harry B. Hanchett, Torrington, secretary-treasurer.——Windham County Medical Society at its twelfth annual meeting held in Hartford, April 18, elected Dr. Joseph A. Girouard, Willimantic, president; Dr. Arthur A. Chase, Plainfield, vice president, and Dr. Arthur D. Marsh, Hampton, secretary-treasurer.——Tolland County Medical Society at its annual meeting elected Dr. William L. Higgins, South Coventry, president; Dr. Alonzo L. Hurd, Somers, vice president, and Dr. Frederick W. Walsh, Rockville, secretary-treasurer.——Fairfield County Medical Society at its one hundred and twenty-seventh annual meeting held in South Norwalk, April 15, elected Dr. George R. R. Hertzberg, Stamford, president; Dr. Eli B. Ives, Bridgeport, vice president; Dr. Charles W. Gardner, Bridgeport, secretary, and Dr. Henry B. Lambert, treasurer.——Hartford County Medical Association at its annual meeting, held April 1, elected Dr. Thomas H. Weldon, South Manchester, president; Dr. Amos T. Harrington, Hartford, vice president, and Dr. Patrick F. McPartland, Hartford, secretary-treasurer.

DELAWARE

New Health Board Officers.—At the annual meeting of the Dover Board of Health, Dr. L. August H. Bishop was elected president, and Dr. Edwin S. Anderson, vice president.

Governor Approves Bill.—Governor Townsend has approved bills recently passed by the legislature requiring physicians practicing in hospitals as interns, to register with the secretary of the medical council, and relative to reporting and placarding diseases dangerous to public health.

DISTRICT OF COLUMBIA

Building for Medical Society.—Plans have been completed for a drive for two weeks to raise a fund of $100,000 to be used for the erection of a suitable home for the Medical Society of the District of Columbia. The site for this home has already been purchased on M Street, near Connecticut Avenue. The plans provide for a stone and brick structure, two stories and basement in height, to contain two auditoriums, office rooms, etc. Dr. William Gerry Morgan is president of the society and Dr. Edward Y. Davidson is chairman of the building committee.

FLORIDA

New State Officers.—At the forty-sixth annual meeting of the Florida Medical Association, held in Miami, May 20 to 22, under the presidency of Dr. Frederic J. Walter, Daytona, that city was selected as the place of meeting for 1920, and the following officers were elected: president, Dr. William E. Ross, Jacksonville; vice presidents, Drs. Henry C. Babcock, Miami, George A. Davis, De Land, and John A. Simmons, Arcadia.

Personal.—At the annual meeting of the St. Luke's Hospital Association, Jacksonville, April 15, Dr. Jay H. Durkee was elected president.——Herrman H. Harris, Major, M. C., U. S. Army, Jacksonville, who is in charge of a base hospital in Verdun, has been commissioned lieutenant-colonel in the medical corps.——Dr. Joseph Y. Porter, Jacksonville, has been elected honorary vice president of the Florida Anti-Tuberculosis Association.——Drs. Carroll H. Frink, Mirian Mullholland, Joseph Y. Porter, and George H. Gwynn, Tallahassee, have been elected directors of the Florida Anti-Tuberculosis Association, and Dr. Van H. Gwinne, Tallahassee, has been elected a member of the executive committee of the organization.

GEORGIA

Personal.—Dr. Charles H. Watt, Thomasville, has been appointed resident surgeon and Dr. Virgil P. W. Sydenstricker, Decatur, resident physician at the University Hospital, Augusta.——Frank K. Boland, Lieut.-Col., M. C., U. S. Army, Atlanta, who served in France with the Emory Hospital Unit, and later was on duty at Fort McPherson, Ga., has been discharged from the service.

License Revoked.—The supreme court of Georgia recently handed down its decision to the effect that the revocation of the license of William Hancock Lewis, Carrollton, was legal. Lewis contended that the law under which his license was revoked cannot constitutionally be applied in his case. A conviction in Haralson County on a charge of larceny after trust is said to be the ground on which the state medical board revoked his license.

ILLINOIS

Chiropractor Arrested.—Mr. R. D. McKown, a chiropractor of Atlanta, Ill., was arrested by the Department of Registration and Education of the State of Illinois for practicing his profession without a state license.

Tent Hospital for Tuberculous Children.—Because of hospital bed shortage in Chicago, tents for 1,000 tuberculous children have been erected at the Municipal Tuberculosis Sanitarium, Chicago, by order of the health commissioner.

Eye, Ear, Nose and Throat Men Elect Officers.—At the annual meeting of the Ilinois State Medical Society held in Peoria, the eye, ear, nose and throat section elected Dr. Frank Allport, Chicago, president, and Dr. Charles F. Burkhardt, Effingham, secretary.

Opening Lecture of Summer Session.—The opening lecture of the graduate summer quarter in medical sciences at the University of Illinois, College of Medicine, will be delivered by Michael F. Guyer, Ph.D., professor of zoology, University of Wisconsin, on "The transmission of eye-defects induced in rabbits by means of lens-sensitized fowl-serum," Monday, June 9, at 1 p. m.

Personal.—Dr. George F. Suker, Chicago, has returned from military service and resumed practice.——Herman H. Tuttle, Lieut.-Col., M. C., U. S. Army, Springfield, sanitary inspector of the Thirty-Third Division, returned with the division from France.——Lewis Wine Bremerman, Lieut.-Col., M. C., U. S. Army, Chicago, who recently returned from France, has been directed to present a report to the government urging the adoption of a plan of universal military training for the benefit of the young men of the country.——Charles H. Parkes, Capt., M. C., U. S. Army, Chicago, on duty overseas, has been promoted to Major, M. C.——Dr. Camillo Volini and Antonio Lagorio, Chicago, have been made chevalier knights of the Crown of Italy by King Victor Emanuel on account of their services given in war relief.——James A. Harvey, Lieut.-Col., M. C., U. S. Army, commanding officer of Base Hospital No. 84, returned from abroad with the Rainbow Division.

KANSAS

Personal.—Dr. Lydia Allen DeVilbiss, Topeka, director of child hygiene of the state board of health, has resigned to take postgraduate work and to lecture.——Dr. Jacob J. Entz, Hillsboro, has been elected president of the Kansas State Health Officers' Association.

New State Officers.—At the thirty-fifth annual meeting of the Kansas Medical Society held in Ottawa, May 7 and 8, it was announced by Dr. William S. Lindsay, Topeka, that 645 of the 1,400 members of the association have been officers in the service of the United States during the war, and resolutions were adopted endorsing the campaign being waged by the state board of health and especially that part which provides for the facilities for diagnosis and treatment of venereal disease, calling on all physicians of the state to cooperate with the health authorities in their efforts to combat venereal diseases, and urging local authorities to provide for the establishment of cooperation in the state board of health. The following officers were elected: president, Dr. Elmer E. Liggett, Oswego; treasurer, Dr. Lewis H. Munn, Topeka, and secretary, Dr. John F. Hassig, Kansas City.

MICHIGAN

New State Officers.—At the annual meeting of the Michigan State Medical Society, held in Bay City, May 21 and 22, the following officers were elected: president, Dr. Charles H. Baker, Bay City; vice presidents, Drs. Angus McLean, Detroit, Charles N. Sowers, Benton Harbor, Herbert E. Randall, Flint and Peter D. MacNaughton, Calumet. Kalamazoo was selected as the place of meeting for 1920.

MINNESOTA

Preventorium Planned.—The proposed Range Tuberculosis Preventorium will be built on the shores of Esquagama Lake, near Biwabik, where it is proposed to establish a fifty-five-bed hospital.

New Officers.—At the annual meeting of the Range Medical Society held in Virginia, May 14, Dr. Charles B. Lenont, Virginia, was elected president, Dr. Charles W. Bray, Biwabik, vice president, and Dr. William M. Empie, Virginia, was reelected secretary.

Southern Minnesota Association Meeting.—The headquarters of the Southern Minnesota Medical Association, which convenes at Rochester, June 23 and 24, will be at Armory Hall instead of at Hotel Zumbro. A complete list of operations will be published and available at the Armory Hall, at 8 o'clock each morning. The midsummer banquet will be held at the Armory Hall, June 23, at which the members and their ladies will be the guests of Drs. William J. and Charles H. Mayo. The address of the president of the association is "John Williams, Lake Crystal," and not "Rochester," as previously announced. Dr. Antoine Depage, La Panne, Belgium, will appear on the scientific program following the banquet, June 23.

NEW YORK

Small Fee Stimulates Reporting of Communicable Disease.—The township of Islip, L. I., has been successful in stimulating a more efficient reporting of communicable disease by observing the law authorizing the payment of 25 cents to physicians for each case that is reported. Islip, with a population of 20,000, paid twelve physicians $640 during 1918, or an average of $53 to each physician. The payment of this sum of money has also served to call public attention to the importance of the work of the health officer.

Health Department Empowered to Mark Drug Addicts.—Health Commissioner Dr. Royal S. Copeland has been advised by the corporation counsel, William P. Burr, that the board of health has power to make certain changes in the sanitary code relating to the control, identification and classification of drug addicts. After receiving this notification, Dr. Copeland stated that he would immediately go ahead with the health department's program. The form of identification cards to be used has already been determined on and a conference has been held with the police authorities concerning the method of registering and identifying addicts.

Personal.—Dr. Isaac W. Brewer, Geneva, formerly sanitary supervisor in the New York State Department of Health, has been appointed full-time health officer of Watertown, as a result of a competitive examination. The salary is $3,500.——Dr. Hermann M. Biggs, New York, state commissioner of health, has returned from the meeting of the International Red Cross Society in France.——Dr. Edward S. Godfrey, Albany, epidemiologist in the division of communicable diseases in the New York State Department of Health, who has been chief of the health inspection service of the American Red Cross in France, has returned.

Statewide Campaign Against Tuberculosis.—The New York State Department of Health and the Tuberculosis Committee of the Charities Aid Association have planned to cooperate in a statewide campaign against tuberculosis. Thirty-four counties will institute free clinics for the examination of those who have recently become affected with tuberculosis or who have been exposed. Members of the staffs of the tuberculosis sanatoriums will participate in the work. The reason for this vigorous campaign is that there has been an increase in tuberculosis since the influenza epidemic last autumn. Some localities have already established clinics. At Plattsburg such clinics will be held on the second and fourth Thursdays of each month for the present year.

New York City

Personal.—Professor Pedro Chutro of Buenos Aires, who served during the war at Buffon Hospital, Paris, is operating at the Polyclinic Hospital, having come to this country on the invitation of the United States government to demonstrate his method of bone grafting.——Dr. Marion M. Crawford will head the second unit of women physicians, dentists, nurses and motor drivers, now being organized for relief work in Serbia. The unit expects to sail before July 1.

Medical School Closes.—At a recent meeting of the Board of Trustees of Fordham University, it was decided to discontinue the medical department of Fordham University, owing to lack of funds necessary to maintain a first class medical school. The Fordham University School of Medcine has been in existence for fifteen years, and has always shown an annual deficit of considerable proportions. There has been no endowment fund of any kind for the medical school. An effort will be made to secure an endowment fund, and if it proves successful the school will be reopened. There are at present 297 students in the school, sixty-eight of whom will be graduated this month.

Further Opposition to Compulsory Health Insurance.—The Medical Society of the County of New York, at its stated meeting, May 26, passed resolutions approving of the instructions against compulsory health insurance given by the House of Delegates of the Medical Society of the State of New York to its delegates to the House of Delegates of the American Medical Association, and confirmed these instructions to such of the members of the House of Delegates of the American Medical Association as are members of the Medical Society of the County of New York. Vigorous opposition to compulsory health insurance was voiced by most of the speakers at a meeting of the social insurance department of the National Civic Federation, May 24. Among the arguments urged against compulsory health insurance were that it had proved a failure in Germany and Great Britain; that it had greatly increased malingering, and that it had not produced any decrease in the death rate.

NORTH CAROLINA

Personal.—Dr. David A. Stanton has been elected mayor of High Point.——Dr. Andrew J. Warren, Salisbury, has been designated as assistant secretary of the state board of health.——Mr. H. E. Miller has been appointed chief of the sanitary engineering in the state board of health, succeeding Mr. W. H. Booker.——Dr. Charles W. Armstrong, Troy, has been appointed whole-time health officer for Rowan County.——Dr. G. A. Roberts, V. S., Raleigh, for twelve years head of the department of veterinary medicine in the state college, has resigned to become veterinarian in the hygienic laboratory of the medical school at São Paulo, Brazil.——Dr. Buxton B. Williams has been reelected superintendent of public health of Greensboro.

OHIO

State Medical Association Meeting.—At the seventy-third annual meeting of the Ohio State Medical Association, held in Columbus, May 6 to 8, the following officers were elected: president, Dr. James F. Baldwin, Columbus; president-elect, Dr. Charles Lukens, Toledo; secretary, Dr. Herbert M. Platter, Columbus (reelected). Toledo was selected as the next place of meeting.

Personal.—John D. O'Brien, Lieut.-Col., M. C., U. S. Army, Canton, arrived in America, May 23, after twelve months' service in France, and will resume practice in Canton.——Dr. Ward I. Huber, Cleveland, was attacked by holdup men, May 16, and received several stab wounds of the head, neck and shoulders.——Dr. John M. Anderson, Greenville, has been appointed division surgeon of the Pennsylvania System between Columbus and Indianapolis.

Cincinnati

Personal.—Dr. Carey P. McCord, formerly in charge of camp sanitation and disease prevention at Camp Sherman, Chillicothe, has accepted the position of director of the newly created department of industrial medicine and public health connected with the University of Cincinnati.

OKLAHOMA

Personal.—Dr. Lewis E. Emanuel, Chickasha, health officer of Grady County, who is at present on duty in France, has been appointed a member of the state board of medical examiners.——Dr. Allen G. T. Childers, Mulhall, has been appointed health officer of Logan County to succeed Dr. Clarence S. Petty, Guthrie.

War Officers' Organization.—A state organization of medical men who took part in the World War was formed, May 20, at the annual meeting of the Oklahoma State Medical Association, with an initial membership of 125. Dr. Leonard S. Willour, McAlester, was elected president; Dr. Samuel J. Fryer, Muskogee, secretary, and Dr. Rex G. Bolend, Oklahoma City, treasurer.

Hospital Association Formed.—At a luncheon given at Muskogee, May 21, the Oklahoma State Hospital Association was organized. The association will work in conjunction with the state medical association and will hold its meetings at the same time and place. The object of the organization is the standardization of hospial service. The following officers were elected: president, Dr. Fred S. Clinton, Tulsa; vice presidents, Drs. John A. Hatchett, El Reno, and Arthur S. Risser, Blackwell; secretary, Paul R. Fesler, Oklahoma City, and treasurer, Dr. Sessler Hoss, Muskogee.

PENNSYLVANIA

Protective Association Organized.—At the meeting of the Physicians' Protective Association held in Buckingham, May 9, Dr. Fred C. Emery, Fox Chase, was elected president; Dr. Alfred E. Fretz, Sellersville, vice president; Dr. Elwood T. Quinn, Jenkintown, secretary, and Dr. Levi S. Walton, Jenkintown, treasurer.

Philadelphia

Belgian Surgeons at College of Physicians.—Prof. Antoine Depage and Capt. Van De Velde, surgeons to the Ambulance de l'Océan at La Panne, Belgium, addressed a special meeting of the College of Physicians, June 6, on 'Contributions to the Progress in Surgery during the War."

Personal.—Cheney M. Stimson, Major, M. C., U. S. Army, who served with Base Hospital No. 82 at Toul, France, arrived at Newport News, May 24.——Charles A. E. Codman, Major, M. C., U. S. Army, who has been placed in charge of Base Hospital No. 104, the Beau Desert Hospital centered near Bordeaux, has been promoted to the rank of lieutenant colonel, Medical Corps.——Dr. Daniel J. McCarthy, lieut-col., M. C., U. S. Army, recently discharged, has been appointed chief medical director of St. Agnes Hospital.——Dr. John A. White has been appointed resident physician in the bureau of charities, and J. M. Fruchter, outdoor physician.

TEXAS

Personal.—Leslie C. Frank, Sanitary Engineer, U. S. P. H. S., has been appointed director of public health of Dallas. ——Mrs. Frances E. Sullivan, Smithsville, has been appointed a bureau director in the state health department.

Health Officers Organize.—May 14, a conference of health officers of the state was held in Waco, over which Dr. Charles W. Goddard, Holland, state health officer, presided, and an association was organized to be known as the Texas Health Officers' Association, with Dr. Goddard as president, and Dr. Oscar Davis, Anderson, as secretary.

TENNESSEE

New Laboratory Building.—The board of trustees of the University of Tennessee voted $100,000 to the medical school to be used for a new laboratory building to be erected in the rear of the Memphis City Hospital. The new building will have laboratories for pathology, bacteriology, chemistry and physiology.

New Dean at Memphis.—Dr. Leverett D. Bristol, a few days ago was elected dean and professor of bacteriology and public health of the University of Tennessee College of Medicine, Memphis. Dr. Bristol is a graduate in science from Wesleyan University, Connecticut, and a graduate in medicine from Johns Hopkins University. His previous teaching experience has been at Syracuse University College of Medicine, Syracuse, New York; University of Minnesota, Minneapolis, and the University of North Dakota.

WISCONSIN

County Dispensary Opened.—A free medical dispensary is to be opened by Milwaukee County in the Sachs Building, Milwaukee, and the county board has appropriated $30,000 for the maintenance of the institution.

Child Welfare Stations Opened.—The deputy commissioner of health of Milwaukee announces the opening of eight new child welfare stations making a total of fourteen in the city. To these stations parents are urged to bring their children, under school age, for medical treatment.

New County Hospital Plans.—The new Milwaukee County Hospital which is to be erected at Twenty-Fourth and Grand Avenue, Milwaukee, will cost about $1,000,000, and will have accommodations for 500 patients. Plans are being so prepared as to permit the construction of such additional units as may be required.

Personal.—Dr. Carroll D. Partridge, laboratory director of the Milwaukee Health Department, has been appointed full-time health officer of Wausau.——Dr. Fred B. Welch has been appointed health officer of Janesville to succeed Dr. Samuel B. Buckmaster, who had served in that position for fifteen years.——Dr. William E. White has been elected president of the Burlington Public Health Association.——Dr. John L. Callahan has been elected president of the La Crosse Board of Health.

Health Bills.—Among the bills either fully enacted or having passed both houses of legislature are the following: making influenza a reportable disease; authorizing local health boards to order closed schools, churches, theaters and public assemblages for the control of epidemics; legalizing delayed vital records; classing chancroid as a venereal disease; requiring every municipality to establish one or more public comfort stations; creating a department of occupational therapy at county tuberculosis sanatoriums; authorizing counties having county sanatoriums to provide outpatient departments to encourage follow-up activities; prohibiting use of vehicles for purposes of prostitution (a measure for venereal disease control).

CANADA

Dominion Department of Health.—The bill for the creation of a Dominion of Canada Department of Health has been put through the committee stage of the senate without undergoing any substantial amendments.

New "Patent Medicine" Law.—Canada is enacting a new "patent medicine" law which will provide that every "patent" or proprietary medicine must be known by a number and that the manufacturers must obtain an annual license. There will also be appointed in connection with this law an advisory board. Dr. Manion, M.P., advised that the word "cure" should be debarred from all "patent medicine" advertisements.

Inspection of Schoolchildren in Ontario.—There is to be a general inspection of schoolchildren of the Province of Ontario under the direction of the minister of education. Doctors and nurses to carry on this work have been appointed, which, it is believed, will not be completed before the expiration of one year or possibly even two years. A dental inspection will be made at the same time. The inspection will be to a large extent a rural and small town survey. Most of the cities and larger towns have had medical and dental inspections of varying thoroughness.

Ontario Medical Association.—At the annual meeting of the Ontario Medical Association in Toronto, May 28, 29 and 30, Sir St. Clair Thompson, London, England, in addition to reading a paper on "Shakespeare in Medicine," spoke at the annual banquet on postgraduate work in England referring to the establishment of a fellowship in medicine, which would enable medical men in Canada to take advantage of those courses in special work. Dr. Frederick W. Marlow, Toronto, was elected president; Dr. James H. Mullin, Hamilton, vice president, and Dr. Thomas C. Routley, Toronto, secretary.

Inquiries of Ministry.—In reply to inquiries made by Dr. C. A. Gauvreau from Tamiscouata, Que., the government states that it is not its intention during the present session to pass a measure respecting "patent medicines," repealing the act now enforced, that the intention of the government is efficaciously to inspect the preparation and sale of "patent medicines" which contain basic properties of copious doses of alcohol and ingredients to produce abortion, and that it is proposed by the government to establish a board qualified to pronounce *finally* on the character of "patent medicines" as regards the content of alcohol and their toxicity.

Canadian Public Health Association.—At the annual convention of the Canadian Public Health Association with the health officers of Ontario, held in Toronto, May 26 and 27, the following officers were elected: president, Dr. Henry E. Young, Victoria, B. C.; vice presidents, Dr. John A. Amyot, Toronto, Dr. William F. Roberts, St. John, N. B., and secretary, Dr. Robert D. Defries, Toronto. The meeting in 1920 will be held in Edmonton, Alta. The most important item of business was the passing of a resolution favoring the manufacture of arsphenamin by the provincial boards of health, and urging the federal government either to make the products themselves or to allow other companies to manufacture them in Canada.

Control of Venereal Disease.—Another conference of representatives of the different health boards in Canada was held in Ottawa, May 30, at the call of the Dominion government. Major-Gen. John T. Fotheringham presided. A Canadian National Council for combating venereal diseases was formed, and Mr. Justice Riddell, Toronto, was named as permanent chairman. All provincial governments will be asked to cooperate with this council for the suppression of social vices in Canada; and its activities will arrange themselves under four heads: education, recreation, medical treatment and law enforcement. Major Jason S. Joy, head of the Commission on Training Camp Activities of the United States, was present and gave valuable advice as to Canadian propaganda and work. It is proposed to establish clinics throughout Canada where cheap or free arsenical products may be procured.

LATIN AMERICA

Deaths in the Profession.—Dr. Francisco Zayas y Jiménez, dean of the medical profession in Cuba, successful in scientific agriculture and known also for his poetry.——Dr. H. D'Achardi, one of the most promising young physicians of Bogotá, Colombia.

Personal.—The *Repertorio de Medicina y Cirugía* of Bogotá states that Dr. J. Vargas Suárez has been appointed by the government *adjunto ad honorem* at the Legation of Colombia at Washington. During his absence the chair of internal pathology of which he is the incumbent will be temporarily filled by Dr. Juan N. Corpas.

GENERAL

Eye and Ear Men to Meet.—The Pacific Coast Oto-Ophthalmological Society will hold its annual meeting at St. Francis Hotel, San Francisco, August 4 to 6. The secretary of the association is Dr. Aaron S. Green, Shreve Building, San Francisco.

Hospitals for Near East.—The American Women's Hospitals is sending a fully equipped hospital unit to Serbia and another to Palestine. Each of these units will have a mobile hospital with fifty beds, sixteen motor ambulances, with drivers, in addition to the requisite number of doctors and nurses.

New Chairman of Health and Quarantine Committee.—Senator Joseph I. France, Baltimore, is to be the new chairman of the senate committee on public health and quarantine, succeeding Senator Joseph E. Ransdell of Louisiana. Senator France is a graduate of the Baltimore College of Physicians and Surgeons and was secretary of the Medical and Chirurgical Faculty of Maryland in 1916.

Southeastern Sanitarians Meet.—At the annual meeting of the Southeastern Sanitary Association held in Rome, the second week in May, Dr. Edgar A. Hines, Seneca, S. C., was elected president, and vice presidents from the various states were elected as follows: South Carolina, Dr. Baxter M. Haynes, Spartanburg; North Carolina, Dr. C. Curtis Hudson, Charlotte; Tennessee, Dr. M. Jacob, Nashville; Alabama, Dr. Samuel W. Welch, Montgomery, and Georgia, Dr. Homer L. Barker, Carrollton.

The "American Child."—A new magazine, called the *American Child*, appeared for the first time last month. It is intended to deal with child welfare problems, and will be published quarterly by the national Child Labor Committee, as successor to the *Child Labor Bulletin*. The editors of the *American Child* propose to publish the investigations and opinions of experts on child welfare. Owen R. Lovejoy is editor of the periodical; Raymond G. Fuller, managing editor; E. N. Clopper and Ruth McIntire, associate editors, and Wiley H. Swift and Josephine J. Eschenbrenner, contributing editors.

Bequests and Donations.—The following bequests and donations have recently been announced:

Presbyterian Hospital, Philadelphia, a contingent bequest of $2,500 on the death of her sister, by the will of Mathilda J. Jones.

Trudeau Sanitarium, Saranac, N. Y., $50,000; Hebrew Orphan Asylum, $15,000, and the residue of his estate of $200,000 to establish the Kerbs Hospital for Tubercular Diseases, provided a daughter dies without issue, by the will of Edward A. Kerbs.

Jewish Seaside Home, Atlantic City, $500, by the will of Rose Lowenstein.

LaHarpe, Ill., for the construction of a public hospital, the estate of Mary F. Davier, appraised at $30,000.

Johns Hopkins Hospital, Baltimore, about $250,000 by the will of John W. Grace, dependent on the expiration of annuities. *This fund* is to be used in extending the benefits of the pay wards of the institution to persons of moderate means.

Medical Legislation.—Considerable legislation of interest to the medical profession will be introduced at the special session of Congress, which is now fairly well under way. It is understood that several measures to strengthen the Food and Drugs Act will be introduced shortly and these doubtless will throw further restrictions around the manufacture and sale of drugs. Considerable legislation of a medical nature which is the outgrowth of the war and war problems is to be discussed. The first measure of this kind was introduced by Congressman Norman J. Gould on the opening day of the session. It provides that any soldier, sailor or marine, who has been or may be honorably discharged suffering from wounds, injuries or illness incurred in the line of duty shall be entitled to receive surgical or medical treatment from the medical officers of the Army, Navy or Public Health Service free of charge whenever practicable. Medical officers refusing to grant such aid are to be dismissed from the service at the discretion of the President.

Social Hygiene Board Appropriations.—The United States Interdepartmental Social Hygiene Board, through its executive secretary, Dr. T. A. Storey, Washington, D. C., announces the following recent appropriations from the Scientific Research Fund of the board:

Johns Hopkins Medical School (under the direction of Hugh H. Young, M.D., professor of urology, and John T. Geraghty, M.D., associate professor of urology, to Johns Hopkins Hospital): (1) Development of new synthetic drugs for the treatment of gonorrhea. Under the direction of E. C. White, Ph.D., experimental chemist. (2) Manufacture and investigation of a series of new organic compounds in the treatment of syphilis. Under the direction of David M. Davis, M.D. (3) Manufacture and investigation of a series of penetrating organic dyes in the treatment of chancroids. Under the direction of Ernest O. Swartz, M.D., Cincinnati. (4) Experimental study of various methods of early treatment of venereal infection with the object of developing simpler technic, more efficient and less expensive drugs. Under the direction of William Jack, M.D.

University of Wisconsin Medical School (under the direction of Arthur S. Loevenhart, M.D., professor of pharmacology): An attempt to prepare mercurial and arsenical compounds which have a predilection for the central nervous system, in the hope of finding drugs more useful than any known in the treatment of syphilis of the central nervous system.

League of Red Cross Societies.—The League of Red Cross Societies, the purpose of which is to associate the Red Cross societies of the world in a systematic effort to anticipate, diminish and relieve misery produced by disease and calamity, was formed at Paris, May 7, 1919. The founder members of the league are the Red Cross societies of the United States, Great Britain, France, Italy and Japan, which will invite other Red Cross societies into membership. While the league will establish relations with the various governments, it is purely a voluntary organization, nonpolitical, nongovernmental and nonsectarian. The objects of the league as formally set forth in the articles of association are:

1. To encourage and promote in every country in the world a duly authorized, voluntary National Red Cross organization, having as purposes improvement of health, prevention of disease, and mitigation of suffering throughout the world, and to secure the cooperation of such organizations for these purposes.

2. To promote the welfare of mankind by furnishing a medium for bringing within reach of all peoples the benefits to be derived from present known facts and new contributions to science and medical knowledge and their application.

3. To furnish a medium for coordinating relief work, in case of great national or international disaster.

The control of the league will be by a general council composed of representatives of all members of the Red Cross societies meeting at designated periods. In the intervals between meetings control will be exercised by a governing board of fifteen members elected by the general council and two ex-officio members. The board of governors, which held its first meeting, May 7, consists of Henry P. Davison of the American Red Cross, Sir Arthur Stanley of the British Red Cross, Comte Kergorlay of the French Red Cross, Count Frascara of the Italian Red Cross, and Professor Ninigawa of the Japanese Red Cross. Mr. Davison was elected chairman of the governing board. Geneva is the headquarters of the league.

FOREIGN

The Victory Meeting.—Some of our exchanges in other countries mention the Victory Meeting with appreciation and congratulations, and reproduce the notice sent out by the Association asking the Allied governments to send delegates, *en vue d'établir les liens d'une amitié durable entre médecins.*

Physicians in the German Peace Delegation at Paris.—The *Paris Médical* states that the German delegation includes twenty physicians: Drs. Landberg, minister of the empire; Carl Melchior; Max Cahen; Schroeder, undersecretary of state; Richter; von Becker; Schall; Hans Meyer; Bosch; Mühling; Kaufmann; Goldmann; Hirth; Lothringer; Manteler; Hirsch; Herschmann, and Professors Schücking and Bier.

Pasteur Institute at Athens.—The *Grèce Médicale* states that an Athens philanthropist has donated the funds necessary to organize a service for treatment of rabies at Athens, and Dr. Sergent, director of the Pasteur Institute in Algeria, has gone to Athens to advise in its construction. In the meanwhile the service will be installed in a rented building, and Sergent has the work well under way.

Meeting of the Internists of the Northland.—The *Hygiea* states that the Ninth Nordisk Congress on Internal Medicine is to convene at Copenhagen August 18-20, 1919. The subject appointed for discussion is the influence of the diet in the treatment of insufficiency of the heart and kidneys. Professor K. Faber will preside, and the main addresses are to be made by Dr. Rubon of Copenhagen and Dr. K. Motsfeldt of Christiania. Dr. V. Scheel is secretary, address Bispebjærgs hospital, Copenhagen.

University Interchanges.—A committee was formed this year at Lisbon to promote interchange of professors between Portugal and other countries, and the *Medicina Contemporanea* reports that a series of six successful lectures has recently been delivered at Lisbon by Prof. F. Lagrange of the chair of ophthalmology at the University of Bordeaux. He spoke in particular on the progress realized in ophthalmology during the war and on the relations between general disease and disease of the eyes, and described his implant method for preparing the socket for an artificial eye. Professor Lagrange also delivered a similar series of lectures at Madrid.

Meeting of the Surgeons of the Northland.—The Twelfth Nordisk Surgical Congress meets at Christiania, July 3-5, 1919. The topics appointed for discussion are "Gastric and Duodenal Ulcer"; "Premature Separation of Normally Located Placenta," and "Cancer of the Rectum." Prof. K. Brandt will preside, and Dr. J. Borelius is the general secretary. The leading addresses are to be distributed already printed, and only a fifteen minute summary will be delivered. Among other communications announced is one by Prof. R. Bárány on primary suture of wounds of the brain, and one by Tengwall on the findings with functional kidney tests as indications for prostatectomy.

Scandinavian Physicians Organize.—The war has brought the three great Scandinavian countries much closer together as they realized the advantages of cooperative action in various fields, economic, scientific, etc., and the benefit from pooling production to render these three great neutral countries independent of other countries. To promote a still closer union an organization has been formed, the "Norden," with nominal dues and a board of managers to consist of 100 members. Among the delegates from Denmark on the board are four physicians, Drs. K. Faber, Heerfordt, E. Hein and V. Scheel. The latter is editor of the *Ugeskrift for Læger.* In fact, physicians have been mainly the pioneers in the movement.

The Achúcarro Prize in Histology.—To honor the memory of this eminent Spanish histologist, whose untimely death was chronicled last year, his family has founded a prize of 1,000 pesetas to be awarded biannually for the best work that has been published in the four preceding years on normal or pathologic histology. The prize will be awarded alternately in Spain and abroad. In Spain it can be given for the best work on general biology or the total works of an author, as well as for work in histology. Abroad, the field is limited to histology of the nervous system. The board of awards consists of Profs. Ramon y Cajal and L. Simarro, with the laymen, the marqués de Palomares and Severino Achúcarro. The prize is to be awarded this year to a Spanish writer.

Graduate Course on Tuberculosis at *Madrid*.—The Tuberculosis Preventorium and Dispensary at Madrid has opened what is called the Escuela de Tisiología, for training in the prevention and treatment of tuberculosis. There are to be two courses, each of three months, and the instruction is to be practical to the utmost. By March 28, thirty-eight physicians of Madrid and the provinces had enrolled for the course. Dr. T. Latour has charge of the subject of seashore sanatoriums; Dr. Calatayud, of electricity; Dr. Mayoral, of laboratory procedures; Dr. Bastos, of bone and joint tuberculosis, and Dr. López Durán, of clinical examinations. The *Revista de Medicina y Cirugía Prácticas* states that the new school does not receive any support from the public authorities.

Deaths in the Profession Abroad.—Dr. J. P. Carles, *agrégé libre* of pharmacy and chemistry at the University of Bordeaux until his retirement in 1904, president of the Société de Pharmacie, lauréat of the Académie des sciences, and of the Academie de médecine, aged 74. He did pioneer work in various lines of the chemistry of drugs and foods and published numerous articles. He was on the editorial staff of the *Journal de médecine de Bordeaux*, and his son carries on his traditions with this journal and also in the medical faculty, as *agrégé de médecine*. —— Dr. Gino Menabuoni, an Italian pediatrist, aged 38, whose writings are well known. For the last three years he has had charge of the pediatric clinic of the University of Siena, and was on the editorial staff of the *Rivista di Clinica Pediatrica* of Florence.

Report of South African Influenza Commission.—The commission appointed by the governor-general of the Union of South Africa to study the influenza epidemic, recently made its report in which the various phases of this problem were discussed. The commission found no evidence that influenza is an air-borne disease and saw no reason to question the validity of the theory that influenza is spread by contact. The general trend of the evidence submitted was that the spread of the disease was facilitated and accelerated by the railways. The commission was also of the opinion that there is some reasonable doubt as to whether the influenza bacillus or any of the other organisms so far found associated with the disease are the true causative agents of the disease. There is no specific cure for the disease. Very detailed recommendations were made on how to handle future outbreaks of influenza.

Change of Name of the "Nordiskt Medicinskt Arkiv."—The editorial staff of these important archives of the Northland announce that henceforth it is to be known as the *Acta chirurgica scandinavica* and the *Acta medica scandinavica*, instead of its present title as the medical and surgical sections of the *Nordiskt medicinskt Arkiv*. It aims for a wider international scope in its publications and readers, the communications to be published in any of the principal languages the writer prefers. This high class journal was founded by Axel Key in 1869, and thus has now reached its semicentennial. It has been indexed regularly for many years in our Foreign Current Literature Department, but was among those shut off by the war. The *Acta otolaryngologica* and the *Acta mathematica* have already appeared, and maintain the high standard of these other Scandinavian Archives which they continue under another name.

CORRECTION

"Report of Throat Cultures in Measles."—In an article by Dr. R. H. Knowlton, The Journal, May 24, the heading as given makes it appear that the work was done in Takoma Park, D. C. The author writes that the data were collected at the Base Hospital, Columbia, S. C.

MEXICO LETTER

City of Mexico, May 25, 1919.

The National Medical Association

On the initiative of a group of leading physicians, a number of meetings have been held to deliberate the question of the advisability of founding in this country a National Mexican Medical Association like those that exist in other countries, to promote the moral and economic welfare of the profession and raise the standards of medical education, etc. It was decided to call a general meeting which is to be held in one of the assembly rooms of the Y. M. C. A. building. Dr. G. Mendizábal, well known as a speaker and as a cultured and honorable member of the profession will address the meeting, explaining the objects of the proposed association. Dr. D. Vélez, ophthalmologist, and Dr. Godoy Alvarez, gynecologist, have been particularly prominent by the enthusiasm they have displayed in regard to the project, which, it is hoped, will culminate in a fine reality.

University Notes

Lic. Macias, rector of the university here, has been invited to take part in the ceremonies at the University of Arizona in the coming July, and it is expected that he will accept the invitation.——Reciprocally, Mr. R. B. von Klein Smid, who is president of the University of Arizona, has been invited through the Mexican Embassy at Washington to come to this country, and a committee appointed by the University is to proceed to the frontier to welcome him and escort him to the capital.——Prof. D. C. Reiche has been appointed to the chair of biology in the Escuela de Altos Estudios.——The resignation of Dr. Terrés was not accepted, and he will continue at his post as professor of clinical medicine where he has been so successful.——Dr. Jesús Arroyo, professor of histology in the medical faculty, has been elected a member of the Academia de Medicina, his address on the colloidal gold reaction having won him this distinction.

Medical Publications

The rather short list of medical journals in Mexico has just been enriched with two new ones, the *Revista del Hospital Militar de Orizaba* which has just started publication in the town of this name in the state of Veracruz. It is to be devoted mainly to topics of military medicine. Col. Dr. Cándido Nieto is the director. The other new journal is the *Archivos Médicos del Norte*, which is being issued in the city of Torreón in the cotton district of the state of Coahuila. The director is Dr. F. de Rosenzweig, a surgeon well known here and in the northern part of the country.

Cordial Reception to Red Cross Medical Delegate

Dr. R. R. Vértiz, delegate from the Mexican Red Cross to the international conference at Berne, writes from New York of the cordial welcome he received from the personnel of the North American Red Cross, both at the city of Washington and in New York. He had to go to Washington to have his passports made out. This Mexican physician was delighted with the "cortesia exquisita" shown him in the neighbor country, and the letter in which he expressed these sentiments was given to the press for publication.

Death of a Mexican Delegate

A cablegram from Montevideo has just announced the sudden death of D. Amada Nervo, perhaps the leading Latin-American poet of our day, minister from Mexico to Argentina and Uruguay, and delegate from Mexico to the Child-Welfare Congress, the Congreso del Niño.

PARIS LETTER

Paris, May 15, 1919.

The Red Cross of America and of the Allies

The American Red Cross proposes to reorganize its activities so that its essential purpose will be to afford relief, especially to the repatriated inhabitants of the devastated regions of France and Belgium. The Red Cross Societies of the Allies have formed a league, and President Wilson has addressed a letter to Mr. Henry Davison, president of the league, extending congratulations on his having successfully united all the Red Cross societies in a common effort to relieve misery, the result of disease and great calamities.

A Memorial to Professor Landouzy

A committee has been formed consisting of colleagues, students and friends of Professor Landouzy to secure funds by subscription with which to establish a Landouzy Museum at the Faculté de médecine de Paris and to strike off a medal to be given to subscribers. Subscriptions may be sent to the treasurer of the committee, M. P. Masson, 120, boulevard Saint-Germain, Paris.

Bestowal of the Fourragère on American Sanitary Companies

American Sanitary Companies 539 and 625 have been decorated with the fourragère combined with the colors of the croix de guerre.

Brazilian Physicians made Members of Legion of Honor

Colonel Nabuco de Gouvea, chief of the Brazilian military mission in France, has been made a commander of the Legion of Honor. Dr. Mourier, undersecretary of state for the Army Medical Corps, praised the Brazilian mission for the work done by its medical corps during the war and for the services rendered by the Brazilian hospital at Vaugirard, which was organized by Colonel Nabuco de Gouvea. Drs. Borges da Costa, Parreiras, Horta and Montenegro, chiefs of service in this hospital, have been awarded the cross of a chevalier of the Legion of Honor.

Use of Refrigerated Meats

At a recent session of the Académie de médecine, M. Martel, director of the veterinary and sanitary services of Paris and of the department of the Seine, stated that the use of refrigerated meat has increased considerably in France.

For several months past Paris and the contiguous territory alone have used from 200 to 250 tons per day.

The chemical changes which take place under the influence of prolonged cold are comparable to those sustained by the so-called *rassic* which the large cities have been using for some time, except that the action of the bacteria on the surface is considerably reduced.

Death of Eminent Chemist

Dr. J. P. Carles, associate professor on the Bordeaux medical faculty and corresponding member of the Academy of Medicine since 1902, is dead.

Personal

At a meeting held May 13, the Academy of Medicine elected four national correspondents: Dr. Paul Courmont, professor of experimental and comparative medicine on the Lyons medical faculty; Dr. Lemoine, medical inspector of the army; Dr. Pachon, professor of physiology on the Bordeaux medical faculty, and Dr. Remlinger, director of the Tangiers Pasteur Institute.

At its last meeting the council of the Paris medical faculty elected four professors: Dr. Ménétrier, associate professor and hospital physician, was made professor of the history of medicine. Dr. J. L. Faure, associate professor and hospital surgeon, was made professor of clinical gynecology. Dr. Duval, associate professor and hospital surgeon, was made professor of clinical surgery. Dr. Gosset, associate professor and hospital surgeon, was made professor of operative medicine (médecine opératoire).

LONDON LETTER

London, May 14, 1919.

"Patent Medicine" Advertisements

In the discussion on the second reading of the ministry of health, Lord Buckmaster said that the only objection to the bill was that it did not go far enough. He would like to have seen some better provision made to enable knowledge of the laws of health to be extended. One of the most important duties to be undertaken in connection with this bill was the control of advertisements relating to "patent medicines" and patent foods. Unless control were effected through this ministry of health, it would never be effected at all. The reason is this: The value of the advertisements of these patented articles is so vast that there is no journal which dares expose the mischievous character of these preparations for fear of finding a loss instead of a profit indicated by its balance sheets. Some of these "patent medicines" are deliberately deleterious, and, in many cases, cause damage to children's health. If the ministry lacks authority to deal with the evil, the needed power should be given it. In the government reply to the discussion, nothing was said on this important topic.

The Ravages of Ankylostomiasis in Queensland

Dr. Lambert, who is investigating ankylostomiasis in Queensland for the Rockefeller Foundation, declares that 23 per cent. of the population of the coast are infected. He says that if the ravages are not combated, a degenerate race will result in a few generations. This statement evoked a sharp contradiction in the columns of the *Times* from the high commissioner for Australia, and from the agent general for Queensland. It was, however, borne out by the eminent helminthologist, Dr. R. T. Leiper of the London School of Tropical Medicine. He quoted the first progress report of the Queensland hookworm campaign conducted by the department of public health under the advice of, and in close affiliation with, the Australian Institute of Tropical Medicine, which was published in 1918. The region surveyed extended over 2,000 square miles, embracing 280 miles of coastal country, from Cooktown to Townsville, with a population of 14,137. The canvass was so carefully conducted that of this total no fewer than 11,678 persons voluntarily submitted to examination for hookworm. Of these, 2,623 were found to be infected. Dr. Leiper also quoted the report of the Queensland Department of Public Instruction on the effects of hookworm infection on the mental development of North Queensland schoolchildren, which was published in January last. The report says: "The direct outcome of the results of such a blighting disease, which is preying on 40 per cent. of the total school population from Cooktown to Townsville, and which is stamping serious mental, physical and sexual degeneracy on 25 per cent. of the total school population, can be nothing other than the weakening of the social fabric and the unfitting of the coming generation for the struggle for existence. Indeed, the tendency of the disease, if not controlled, is toward the obliteration of the race through the unsexing of its victims and the reducing of individual resistance toward acute infections such as pneumonia and tuberculosis."

The Medical Parliamentary Committee

The formation of the Medical Parliamentary Committee was described in a previous letter to The Journal. Its objects are to increase medical representation in Parliament, to supply information of the trend of expert opinion on health questions, and to supply early information on impending legislation to the various medical organizations which are represented on the committee. These comprise most of the medical organizations, such as the Society of Health Officers, the Medical Women's Federation, the State Service Association, the British Dental Association, the National Medical Union and the Medico-Political Union. After some hesitation the British Medical Association, which has always held that its political activities cover every field and that, therefore, other medicopolitical bodies are superfluous and even detrimental by dividing the profession, has so far recognized the Medical Parliamentary Committee as to send representatives to a conference which has been held under the presidency of Sir Watson Cheyne, M.P. In proposing the first resolution, Dr. A. Latham emphasized the point that the Medical Parliamentary Committee was a temporary body appointed only for the purpose of devising some scheme whereby the opinions of the profession can be focused, and by means of which, through increasing parliamentary representation or through agitation they may be conveyed to the public. He said that in the near future health questions are bound to loom large in all legislation. He declared that the medical profession consists of men engaged in a number of different types of work—factory, colliery or other industrial forms of practice, general practice among the poor and well-to-do, medical officers of health, school physicians, navy, army and air force physicians, specialists, consultants, and men engaged in research; and stated that health questions in time of peace are as complex as any that arise in the management of an army. Any medicopolitical question, he said, would be looked at by different sections of the profession from different angles, and some organization was necessary whereby representatives of each of these sections might be brought together.

At present there is no organization of the profession representing the whole body, he pointed out. Nearly all existing bodies, moreover, have had too much work arising out of their special aims to permit them to give much time to political developments, while nearly every one has been suspected of furthering the interests of the profession at the expense of the public good. This is fatal to medical progress. If the new body is to be successful it must obtain increased political influence, and for that must secure the confidence and sympathy of the public, he said. It must be recognized as looking after the community rather than after the physician; and this is proper, for the interests of the physician will be cared for if the interests of the community are met. The medical profession has made a mistake in the past in not leading the public to understand that the interests of physicians are wrapped up in the interests of the community. Unfair conditions of service will produce a discontented profession and bad work.

Sir Thomas Verrall addressed the meeting as representative of the British Medical Association. He said that he could not avoid pointing out that the association did all the things claimed by the Medical Parliamentary Committee. If it were left to the association to establish a permanent parliamentary committee, as he thought would be wise, the association would probably agree that there should be a permanent parliamentary committee of some kind. It would be necessary to present to all members of Parliament a right view of health questions. The custom of the association had been to communicate not only with medical members of Parliament but also with all heads of departments. He would not oppose the formation of a permanent medical parliamentary committee, but he hoped that for the present the question of its construction would be left open. A resolution was then carried that the committee consist of: (*a*) a representative or representatives of any society or association of registered dental or medical practitioners having as its objective, or taking an interest in, medicopolitical activity; (*b*) two representatives appointed by the nursing profession; (*c*) a representative of midwives; (*d*) a representative appointed by the Pharmaceutical Society; (*e*) a representative appointed by the British Hospitals Association; (*f*) the editor of: (1) the *British Medical Journal*, (2) the *Lancet*, (3) the *Medical Press*, (4) the *Medical World* and (5) the *Medical Times;* (*g*) all medical members of Parliament, and (*h*) members, not exceeding 20 per cent. of the elected representatives of the whole medical profession, to be elected as soon as the committee's financial position warrants the necessary expenditure.

An Atlas for the Blind

One of the latest productions of the National Institute for the Blind is a geographic and industrial atlas of the British Isles. The book is the outcome of years of experimenting and improvement on old maps for blind people; for the providing of a map that can be studied by means of the finger-tips has proved immensely difficult. Largely owing to the efforts of Mr. H. M. Taylor, F. R. S., of Cambridge, himself sightless, the work is a great advance over anything achieved before. It is very complete, and follows to the smallest detail the ordinary printed atlas. Towns, rivers, boundaries, coast-lines, mountain ranges, and railways are all distinctly marked. Each one of these has a number marked against it which corresponds with a key on the page opposite the map. The volume is a large one, containing 222 pages, twenty-one of which are maps, and is bound in cloth boards. The price is only half a dollar.

Marriages

Charles Wallis, Lieut., M. C., U. S. Army, Arkadelphia, Ark., on duty at Fort Brady, Mich., to Miss Eva Isabelle Feetham, of Sault Ste. Marie, Mich., May 24.

Douglas Heath Nisbet, Lieut., M. C., U. S. Army, Boston, on duty at Charlotte, N. C., to Miss Thelma Russell of Marlboro, Mass., May 7.

James Michael McTiernan, New York City, to Miss Florence Morgan Cadwell of Hartford, Conn., in New York City, May 17.

Montague Laffitte Boyd, Atlanta, Ga., to Miss Margaret Phillips of La Grange, Ga., recently.

Thomas Rodman Goethals, Boston, to Miss Mary Addison Webb of Washington, D. C., June 3.

Julius Hiram Comroe, to Miss Catherine L. Baker, both of York, at Philadelphia, May 16.

Robert Addison Milliken, Indianapolis, to Miss Mildred Post of New Orleans, May 20.

Deaths

James Herbert Stowell ⊕ Chicago; Northwestern University Medical School, Chicago, 1881; aged 65; a specialist in internal medicine; a member of the council of the Chicago Medical Society and president of the Society in 1900-1901; once chairman of the Medical Section of the Illinois State Medical Society; a member of the consulting and examining board of Cook County Hospital; attending physician to the Chicago, Baptist and Samaritan hospitals; medical director of the United States Annuity and Life Insurance Company; died suddenly at his home, May 31, from heart disease.

Nelson R. Gilbert, Bay City, Mich.; Cleveland University of Medicine and Surgery, 1871; aged 77; president of the board of control of the Home for the Feeble-Minded and Epileptics, Lapeer, Mich.; for four years treasurer of Otsego County; for six years chairman of the board of health, and city physician of West Bay City, and for many years physician of Bay County; died at his home, May 19.

Alexander Lyle ⊕ New York City; New York University, New York City, 1888; aged 52; professor of surgery in the Polyclinic Medical School and Hospital, New York City, since 1908; attending surgeon to the City Hospital, Blackwell's Island; a fellow of the New York Academy of Medicine; died at his home, May 23.

Samuel Hendrickson, Jamaica, N. Y.; College of Physicians and Surgeons in the City of New York, 1875; aged 69; a member of the visiting staff of St. Mary's Hospital, Jamaica; at one time sanitary superintendent of the department of health for Queens' County; died at his home, May 20, from heart disease.

Roderick Colin McLennan, Syracuse, N. Y.; College of Physicians and Surgeons in the City of New York, 1886; aged 61; consulting surgeon to the Syracuse Women's and Children's Hospital; a charter member and once president of the Syracuse Academy of Medicine; died at his home, May 15.

Edwin Field Sampson ⊕ Lieut., M. C., U. S. Army, New York City; Harvard Medical School, 1909; aged 36; on duty at Camp Zachary Taylor, Louisville, Ky.; a member of the staff of Bellevue Hospital; died at the base hospital, Camp Taylor, April 22, from hemolytic streptococcus pyemia.

John Herman Eden, New York City, and Great Neck, L. I., N. Y.; Yale University, New Haven, Conn., 1873; aged 69; formerly a member of the staff of Bellevue Hospital; died at his home in Great Neck, May 19, from heart disease.

William Bernard Rasing ⊕ Cleveland, Ohio; Cleveland College of Physicians and Surgeons, 1908; aged 33; a member of the Cleveland Academy of Medicine; a specialist in urology; died at his home, May 20, from pneumonia.

Simpson Matthew Ekermeyer, New Bremen, Ohio; Eclectic Medical Institute, Cincinnati, 1881; aged 58; a member of the Ohio State Medical Association; died in a sanitarium in Columbus, Ohio, May 5, from cerebral hemorrhage.

James Mitchell Taylor, Chicago; Homeopathic Medical College of Missouri, St. Louis, 1869; aged 71; a member of the Illinois State Medical Society; died at his home, May 26, from pneumonia following a surgical operation.

Nathaniel L. Edwards, Bluefield, W. Va.; (license, West Virginia, 1900); aged 49; a colored practitioner; proprietor of the Mercer Sanitarium, Bluefield; died at that place, February 24, from meningitis following influenza.

Edwin Everett Smith, Cold Spring, N. Y.; Long Island College Hospital, Brooklyn, 1871; aged 74; a psychiatrist; a life member of the Medico-Psychological Association; died at his home, May 24, from valvular heart disease.

Myron Lawrence Marr, Dorchester, Boston; Bowdoin Medical School, Brunswick and Portland, Me., 1879; who had been in the construction business for several years; died in New York, May 21, after a surgical operation.

August Beil, Selby, S. D.; New York Homeopathic Medical College, New York City, 1896; aged 56; a member of the South Dakota State Medical Association; died at his home, April 17, from disease of the heart and kidney.

Bertha Barbara Schroeder, Chicago, Loyola University, Chicago, 1908; aged 34; a member of the Illinois State Medical Society; died in Mercy Hospital, Chicago, June 1, from heart disease.

George Washington Carr, Fort Deposit, Ala.; University of Pennsylvania, Philadelphia, 1855; aged 84; a surgeon in the Confederate Service throughout the Civil War; died at his home, May 11.

William Wheeler Squire, Visalia, Calif.; Hahnemann Medical College, Chicago, 1876; Rush Medical College, 1875; aged 71; formerly mayor of Visalia, died at his home, May 17, from cancer.

Henry A. Bremmer, Ashton, Ill.; Chaddock School of Medicine, Quincy, Ill., 1886; aged 67; health officer of Ashton; died in the Lincoln (Ill.) Hospital, May 11, from heart disease.

Frank Litten ⊕ Austin, Tex.; Jefferson Medical College, 1887; aged 54; was found dead in his automobile, in the mountains about seven miles from Austin, May 16.

Samuel Thomas Tapscott, Searcy, Ark.; Memphis, Tenn.; Medical College, 1858; aged 85; for forty years a resident of Searcy; died at his home, May 14.

Commodore P. Barrett, Mount Vernon, Ind.; Hospital College of Medicine, Louisville, Ky., 1898; aged 49; died at his home, March 17, from brain tumor.

Charles E. Emerick, Harrisburg, Pa.; University of Pennsylvania, Philadelphia, 1886; aged 62; died at his home, May 4, from erysipelas.

Robert Franklin Burton, Little Rock, Ark. (license, State Medical Board, Arkansas, 1903); aged 44; died in Fowler, Colo., May 4.

Valentine Jacob Bold, Philadelphia; Jefferson Medical College, 1890; aged 50; died at his home, May 21, from heart disease.

Frederick W. F. Riehl, Alameda, Calif.; University of Berlin, Germany, 1867; aged 76; died at his home, May 21.

⊕ Indicates "Fellow" of the American Medical Association.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

COLLOSOL PREPARATIONS

Report of the Council on Pharmacy and Chemistry

The Council has adopted and authorized publication of the report which appears below declaring "Collosol Argentum," "Collosol Arsenicum," "Collosol Cocain," "Collosol Cuprum," "Collosol Ferrum," "Collosol Hydrargyrum," "Collosol Iodin," "Collosol Manganese," "Collosol Quinin" and "Collosol Sulphur" inadmissible to New and Nonofficial Remedies, because their composition is uncertain (conflict with Rule 1). In the few cases in which the therapeutic claims for these preparations were examined, the claims were found to be so improbable or exaggerated (conflict with Rules 6 and 10) as to have necessitated the rejection of these products.

W. A. Puckner, Secretary.

The Anglo-French Drug Co., Ltd., London and New York, in November, 1918, requested the Council to consider the products "Collosol Argentum," "Collosol Arsenicum," "Collosol Cocain," "Collosol Cuprum," "Collosol Ferrum," "Collosol Hydrargyrum," "Collosol Iodin," "Collosol Manganese," "Collosol Quinin" and "Collosol Sulphur." The term "Collosol" appears to be a group designation for what are claimed to be permanent colloidal solutions, marketed by the Anglo-French Drug Co., Ltd. Were this claim correct, "Collosols" should contain their active constituents in the form of microscopic or ultramicroscopic suspensions, protected against spontaneous precipitation by the presence of proteins or some similar "stabilizers."

According to the original patent specifications for Collosols, the metals are precipitated or treated with "peptone," which acts as the suspending or stabilizing agent. The method of using the peptone makes it doubtful, in the first place, whether the major part of the metals is present in colloidal form, or merely in the form of peptonates, i. e., as ordinary salts. Moreover, the later patents indicate that the products have been unsatisfactory; "experience having shown that some metal colloids under certain conditions not yet fully understood have the tendency to break down after a certain period" (U. S. patent No. 1,116,247). Phenol, it is claimed, has a tendency to counteract this decomposition, and the patent covers the use of phenol for this purpose.

It is difficult to see how phenol could possibly have such action. In fact, it obviously does not, for a number of the samples of Collosols submitted to the Council had separated. For instance, "Collosol Hydrargyrum" was not a colloidal solution at all, but a suspension of a coarse powder. The ampules of "Collosol Ferrum" contained a considerable quantity of flocculent precipitate. If either of these preparations were injected intravenously as directed, death might result, making the physician morally if not legally liable.

The recklessness of the claims is further illustrated by the advice that these indefinite mixtures of poisonous metals can be injected in unlimited quantities. Thus, Henry Crookes stated (*Chemical News*, May 7, 1914, p. 218) that Collosols "contain so small a proportion of metal, viz., 1 in 2000, that even a poisonous body like arsenic can be used with impunity." He stated that they may be applied as a lotion, intramuscular or intravenous injection, and that "one pint or more can be injected intravenously."

In the case of "Collosol Cocain," as was brought out in the Council's report published in The Journal, April 12, 1919, the manufacturers have admitted that the product is not what they have claimed—and still claim—for it. The report of the A. M. A. Chemical Laboratory showed that "Collosol Cocain," instead of containing 1 per cent. cocain as claimed, contained, in fact, at most not more than 0.4 per cent. cocain.

The report of the A. M. A. Chemical Laboratory on the Collosol products was sent by the Council to the New York office of the Anglo-French Drug Co., Ltd., in duplicate, in order to facilitate reference to the London office. This was some months ago. The information which the Council requested has not yet been received, nor has the Anglo-French Drug Co., Ltd., indicated its intention of supplying such information. On the other hand, claims to which specific objection have been made, continue to appear in current advertising. Accordingly, the Council authorizes publication of this report, and declares the Collosol preparations previously named ineligible to New and Nonofficial Remedies.

Correspondence

"MALARIA CONTROL IN THE FUTURE"

To the Editor:—My attention has been drawn to an editorial appearing in The Journal (**72**:1465 [May 17] 1919), entitled, "Malaria Control in the Future." I feel that I must take exception to this editorial on most important matters both of principle and of fact. First, in the fore part of the editorial is the statement:

> Few organizations or governments could aspire to cope with the malaria problem as efficiently and successfully as is likely to be done by the International Health Board of the Rockefeller Foundation. . . .

I cannot too strongly condemn a statement of this character appearing in the columns of a journal such as The Journal of the American Medical Association, for the following reasons: 1. It apparently concedes the hopelessness of the control of malaria as an official governmental activity, either of the federal government or of the states. This is not only absolutely wrong in principle, but is not in accord with the facts. 2. Not only is the United States Public Health Service at the present time engaged in cooperation with states and localities in eradicating malaria in seventeen different localities and in nine different states, but during the war it instituted malaria control in connection with the work of extracantonment sanitation over an area ten times as great as the Panama Canal Zone. At present it has on active duty the finest and most experienced corps of medical officers and engineers, conversant with the work of malaria eradication, which has ever been brought together in the history of the world. The Public Health Service is prepared to maintain this corps of specially trained experts and to add to it for aiding states and municipalities in eradicating malaria. Moreover, owing to the stimulus given to this work by the Public Health Service, practically $750,000 was raised locally during the year 1918 by various municipalities and counties for the purpose of controlling malaria, the operations being supervised by the Public Health Service.

Does this appear as if "few organizations or governments could aspire to cope with the malaria problem as efficiently and successfully as is likely to be done by the International Health Board of the Rockefeller Foundation"?

Passing now from a discussion of the principle contained in the statement, to matters of fact, we find in this editorial that the work of the Rockefeller Foundation in the eradication of malaria has been confined to two specific demonstrations: (*a*) the sterilization of human carriers by the administration of quinin, and (*b*) the control of malaria in one community by screening. The impression given by the editorial is that work of this character had never been done before in this country on such an extensive scale.

The editorial does not state that the plans for this work were prepared by the late Surg. R. H. von Ezdorf of this service, who lost his life in this work, nor that Dr. H. A. Taylor, who was field director at Crosset, received his training in the U. S. Public Health Service, and was transferred from that service to the International Health Board, and that this experimental work was carried out under the immediate supervision of an officer of the federal Public Health Service. Moreover, the first report of this demonstration was published as Public Health *Bulletin No. 88* of this service, in September, 1917. The editorial is singularly unmindful of the fact that field investigations of malaria have been actively and extensively pursued by the Public Health Service since 1912, and demonstrations in the control of malaria have been carried on by the service on an increasing scale until in 1918 the expenditures of the Public Health Service for demonstrations in the control of malaria were in the neighborhood of $1,000,000.

In view of the fact, therefore, that the control of malaria must in this country be a function of official and governmental rather than of unofficial and private agencies, and that this editorial not only ignores the extensive work of the Public Health Service, but implies that malaria control of the future, far from being a government matter is to be conducted by private and unofficial agencies, such as the International Health Board, I cannot but deprecate this publication at a time when the federal Public Health Service requires the fullest support for the necessary increase of its work. Furthermore, the whole tone of the editorial apparently concedes the futility of handling these problems by governmental agencies, and tends to create the impression that such important national health problems must be left to the unofficial and private agencies of the country to solve.

In conclusion, I may say that while at present in sparsely settled districts it may not be practicable for local communities to undertake measures for malaria eradication, the experience of the Public Health Service has shown that, far from being impracticable to induce communities to bear the expense of this work, it is becoming easier all the time; and furthermore the government now has pending before Congress a proposal to buy farm homes for soldiers by utilizing certain areas formerly uninhabitable because of malarial conditions, and to make these habitable and economically productive by the extensive use of malaria control measures which will be undertaken by the Public Health Service.

RUPERT BLUE, Surgeon-General.

ADMINISTRATION OF ARSPHENAMIN

To the Editor:—In his recent communication the director of the Hygienic Laboratory, after detailing what he considers the most important points—adequate dilution and slowness of administration—concludes: "Any physician who fails to observe these precautions should be considered as directly responsible for serious results that follow the improper use of this drug."

This statement, if unchallenged, may prove embarrassing to those physicians whose method of administration differs from that advocated. For the past eighteen months, both in private practice and in the out-clinic work at Touro Infirmary, I have abandoned the large dilutions and the gravity method of giving arsphenamin for the syringe and concentrated solutions. During this period, I have given, or supervised the giving of, approximately 2,000 injections of arsphenamin by the latter method. Our routine practice is to dissolve 0.6 gm. of the drug in 20 c.c. of freshly distilled water. The average dose given to an adult man of normal weight is 0.5 gm. and to a woman, 0.4 gm. In fresh infections, especially before the onset of a positive Wassermann test, we commonly give 0.6 gm. to the man and 0.5 gm. to the woman, repeating this dose weekly for three doses, and then give at least two more injections at longer intervals, with mercury and iodids in some form between and following the later injections.

Not merely once, but hundreds of times, I have injected 0.6 gm. arsphenamin in 20 c.c. of water in from twenty to thirty seconds without the slightest unpleasant results, either immediate or delayed. The slowness of the injection, on which Dr. McCoy lays so much stress, may be of importance when a large quantity of fluid is being introduced, but when the quantity is as small as 20 c.c., rapidity of injection is not significant. Our patients, except a few high-strung persons, are hardly aware that they have taken medication. Even the so-called "nitroid crises" are unusual when the syringe method is used. Since we have been using this method, we have seen less of other complications. We have had no fatalities, only one case of severe nephritis, now entirely well, but one case of jaundice, and four cases of toxic dermatitis preceded by hyperpyrexia. In our series of 2,000 injections, the results will compare favorably with those of other clinics, no matter what method of administration is followed.

The syringe method and concentrated solutions of arsphenamin, because of greater simplicity of administration and saving of time involved, is the method of choice in a busy clinic. It is at least as safe as the technic advocated by Dr. McCoy.

At present I rarely use neo-arsphenamin either in clinic or office practice. While I have had experience with all of the preparations of arsphenamin available, I routinely use that put out by the Dermatological Laboratory of the Philadelphia Polyclinic. The fact that we dissolve this preparation in boiling water without hesitation, and that our results have been uniformly good with it, has made us disinclined to change.

Success in the administration of arsphenamin depends chiefly on the following points: first, the selection of a reliable preparation; second, the use of freshly distilled, boiled water, both for dissolving the arsphenamin and for the sodium hydroxid solution; third, care in selecting the patient and adjusting dosage and frequency of repetition.

A. NELKEN, M.D., New Orleans.

FAS EST ET AB HOSTE DOCERI

To the Editor:—I note with surprise, not to say indignation, that in recent issues of THE JOURNAL abstracts from the *Deutsche medizinische Wochenschrift, Berlin,* have appeared. I wonder what the views of THE JOURNAL'S readers are regarding this untimely recognition of German medical science? Is it possible we are so in need of our enemies' Kultur that we must have it while a state of war still exists between Germany and the United States? Have we as a profession so soon forgotten the refined barbarities, worked out with such patience and success in the laboratories of German scientists and by their dictation and direction so relentlessly carried out by their ignorant tools, the personnel of their armies? Poison gas, liquid fire, ablation of the breasts of women as a token and a warning that they have been ravaged by those who knew themselves to be infected with loathsome diseases — the whole long list of inhuman, almost unmentionable acts — these were not thought out by the German war lords, however much they gloried in them. They were the direct products of German chemists, German sanitarians, German doctors.

With thousands of our boys still standing their watch on the Rhine, with thousands still in military hospitals recovering as far as they may from the wounds of an absolutely unjustifiable war, with those other thousands, hurried to untimely graves on foreign soil, do we ever want more of German science? Can we so soon forget these facts and give aid to the only too apparent renaissance of German propaganda by according its science a place in our national medical journal?

We know how we have been humbugged by purchasing at exorbitant prices literal ship-loads of worthless coal-tar derivatives because they were heralded by the paid testimonials of Herr Professor This, That and the Other. We know the "Made in Germany" stamp put on hundreds of really meritorious discoveries stolen or elaborated from the work of English, French, American and other workers. These facts alone should be enough to make us a bit wary of German science.

But with this deluge of blood scarce staunched, it seems to me most unfitting—nay worse—to give the slightest recognition to German medicine. They are still belligerent. They are absolutely unrepentant, still snorting fire and considering themselves undefeated supermen. Even their peace delegates are haughty, overbearing, ungracious—pigs.

Many think the peace terms too easy. The worst punishment rests with the people. Germans crave publicity. They live and thrive on the reputation of their products carefully built up by this publicity. Ignore them! Condemn them to innocuous desuetude! Their language has been dropped from the school curriculum. Good! Drop their science from our literature. Alas, that it was ever taken up again! If we cannot live without it, let us die patriotically!

Ross G. Loop, M.D., Elmira, New York.

PROTECTION AFFORDED OKLAHOMA HOGS FROM UNQUALIFIED VETERINARIANS

To the Editor:—The following item from the Dallas (Texas) *News* illustrates a principle familiar to every member of the medical profession:

> Oklahoma City, Okla., May 27.—Complaints are being received by J. A. Whitehurst, president of the State Board of Agriculture, from graduate veterinarians that provisions of the 1916 statute relative to vaccinating hogs for cholera place an unnecessary burden upon the veterinarians in requiring examination and bond before they can apply the simultaneous serum and virus vaccination. Mr. Whitehurst applied to the attorney general for an opinion in the matter, and the reply is that however severe the burden may be there is no way to relieve it, and that the provisions of the law must be complied with. Laymen, veterinarians, physicians and all are placed in the same category, says the opinion of the attorney general. They must pass a satisfactory examination at the hands of the veterinary department of the A. & M. College and put up a bond of $1,000 to be approved by the Board of Agriculture.

In this state as well as in many others, the chiropractor and the Christian scientist do business without leave. They practice on human beings, no matter how serious the ailment may be. The osteopaths have to take an examination in their own peculiar theories, though they are allowed to apply these extraordinary theories in the treatment of any disease, chronic or acute. But the poor veterinarian has to qualify professionally and in addition put up a thousand dollar bond before he is allowed to dose the swine! It is said that the most convulsive type of humor is sometimes born of tragedy.

S. H. Landrum, Altus, Okla.

"LIPOVACCINES"

To the Editor:—Allow me to direct your attention to an error in the editorial on "Lipovaccines" in The Journal, May 3, 1919, p. 1297. It is stated that "Le Moignic and Pinoy were the first to substitute oils for the physiologic sodium chlorid solution previously used in making vaccines. . . ." So far as I am able to ascertain the first lipovaccines were made, and their use applied in the prevention and treatment of disease, by myself in 1913 and 1914, and mention of this fact was made in an article entitled "The Vaccine Treatment of Gonorrhea" which appeared in The Journal in 1915. The fact that my associates and I found such vaccines of doubtful utility and abandoned their use is not of material importance in the present consideration. No reference to the work of Le Moignic and Pinoy was given in the editorial, but their article appeared in 1916 (*Compt. rend. Soc. de biol.*, lxxix, p. 201), a year following the note of my own above mentioned.

Carl C. Warden, M.D., Ann Arbor, Mich.

"IDENTITY OF THE POPPY IN FLANDERS' FIELDS"

To the Editor:—There would seem to be some doubt from recent letters to The Journal respecting the particular poppy "in Flanders' fields." This is *Papaver rhoeas*, the common red, or corn, poppy. It flourishes abundantly in the wheat fields of Europe, and many writers have remarked that the crop of poppies the season after a battle is increased. This is probably due to additional fertilization. The fresh petals are supposed to possess slightly narcotic properties. A syrup prepared from these petals has been used as a coloring ingredient. Medicinally the plant is practically valueless, and has of course no connection with *P. somniferum*, the opium poppy, which is the one so often mentioned in connection with sleep by the poets, as:

> "The end of all, the poppied sleep" (Swinburne).

Francis H. Mead, M.D., San Diego, Calif.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

STATISTICS ON ARMY EXAMINATIONS AND VENEREAL DISEASE

To the Editor:—Please send me at your convenience full data concerning: (1) the number of our boys examined medically for the army; (2) number of white men; (3) number of colored men, and (4) percentage of those with venereal disease.

Fanny R. Smith, Chicago.

Answer.—1. The Second Report of the Provost Marshal-General, up to Dec. 20, 1918, indicates that the total number of men examined physically under the Selective Service Law was 3,208,446, of whom 2,259,027—70.41 per cent.—were found physically qualified in Group A; 88,436—2.76 per cent.—were in the remediable Group B; 339,377—10.58 per cent.—were in the limited service Group C, and 521,606—16.25 per cent. —were found physically disqualified and placed in Group D. Out of the 2,124,193 men inducted into service, 172,000, or 8.1 per cent., were rejected later in camp.

2. Of the 3,208,446 men examined, 2,749,608 were white.
3. The colored men numbered 458,838.
4. Out of 467,694 men rejected, both in camp and by local boards, 6,235, or 1.3 per cent., were rejected because of venereal disease. The relative numbers of colored and white with venereal disease are not yet available.

SCARLET FEVER AND DIPHTHERIA STATISTICS IN TEN LARGE AMERICAN CITIES FOR 1917 AND 1918

To the Editor:—Will you please give me the morbidity and mortality statistics of scarlet fever and diphtheria for 1917 and 1918 in the following cities: Baltimore, Boston, Buffalo, Chicago, Cincinnati, Cleveland, New York, Philadelphia, Providence and Toronto?

E. V. Murphy, Montreal, Canada.

Answer.—The morbidity and mortality statistics for scarlet fever and diphtheria in these cities, as reported to us by the health officers, are:

	Population Estimated by U.S. Census Bureau as of July 1, 1916	Scarlet Fever				Diphtheria			
		Morbidity		Mortality		Morbidity		Mortality	
		1917	1918	1917	1918	1917	1918	1917	1918
New York...	5,602,841	6,260	4,460	120	177	12,624	11,455	1,158	1,245
Chicago	2,497,722	13,444	1,809	623	48	10,290	5,708	1,228	720
Philadelphia..	1,709,518	1,464	1,384	31	43	3,141	2,477	441	384
Boston	756,476	1,497	1,126	46	24	4,098	2,832	278	217
Cleveland ...	674,073	618	408	14	11	1,856	1,371	155	109
Baltimore ...	589,621	544	366	11	8	690	671	58	71

Toronto	376,538*	548	1,096	13	33	1,445	1,263	82	97
Providence ...	254,960	423	355	15	18	934	729	80	56

* Toronto population according to 1911 census.

"CAPTAIN OF THE MEN OF DEATH"

To the Editor:—In the interest of accuracy allow me to direct attention to a rather flagrant misquotation in your issue of May 24, page 1541, near the foot of the first column where pneumonia is called "master of the men of death." This should be, I believe, "captain of the hosts of death."

C. Reiterman, M.D., Los Angeles.

Answer.—Neither of the quotations is correct. According to Sir William Osler, Bunyan bestowed on tuberculosis the name of "captain of the men of death." Osler himself says: "One of the most widespread and fatal of all acute diseases, pneumonia, has become the 'captain of the men of death,' to use the phrase applied by John Bunyan to consumption."

ADALIN

To the Editor:—Will you kindly inform me what adalin is? It was brought to my attention in a prescription written by a St. Louis physician, but I am unable to find any literature on the subject.

Stephen Fisher, M.D., New Salem, N. D.

Answer.—Adalin is bromdiethyl-acetylcarbamid, and is described in New and Nonofficial Remedies, 1919, page 64. It is said to be an efficient sedative, reducing excitement and promoting sleep in conditions in which a powerful hypnotic is not required.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Alabama: Montgomery, July 8. Chairman, Dr. S. W. Welch, State Capitol, Montgomery.

Arizona: Phoenix, July 1. Sec., Dr. Allen H. Williams, 219 Goodrich Bldg., Phoenix.

California: San Francisco, June 23-26. Sec., Dr. Charles B. Pinkham, 904 Forum Bldg., Sacramento.

Colorado: Denver, July 2. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

Connecticut: New Haven, July 8-9. Sec., Regular Bd., Dr. Charles A. Tuttle, 196 York St., New Haven; Sec., Homeopathic Bd., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven; Sec., Eclectic Bd., Dr. James E. Hair, 730 State St., Bridgeport.

Delaware: Wilmington, June 17-19. Sec., Dr. H. W. Briggs, 1026 Jackson St., Wilmington.

District of Columbia: Washington, July 8-10. Sec., Dr. E. P. Copeland, The Rockingham, Washington.

Florida: Jacksonville, June 16-17. Sec., Dr. W. M. Rowlett, Citizens Bank Bldg., Tampa.

Florida: Eclectic Board, Jacksonville, June 9-10. Sec., Dr. G. A. Munch, 1306 Franklin St., Tampa.

Illinois: Chicago, June 16-19. Supt. of Registration, Mr. F. C. Dodds, Springfield, Ill.

Iowa: Iowa City, June 12-14. Sec., Dr. Clifford H. Sumner, Capitol Bldg., Des Moines.

Kansas: Topeka, June 17. Sec., Dr. H. A. Dykes, Lebanon.

Kentucky: Louisville, July 1-3. Sec., Dr. J. N. McCormack, Bowling Green.

Louisiana: New Orleans, July 1-3. Sec., Dr. E. W. Mahler, 141 Elk Place, New Orleans.

Maine: Augusta, July 1-2. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.

Wyoming: Cheyenne, June 23-25. Sec., Dr. H. E. McCollum, Laramie.

Massachusetts January Examination

Dr. Walter P. Bowers, secretary of the Massachusetts Board of Registration in Medicine, reports the oral, written and practical examination held at Boston, Dec. 31, 1918, Jan. 2, 16 and 17, 1919. The examination covered 13 subjects and included 70 questions. An average of 75 per cent. was required to pass. Five candidates were examined, all of whom passed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Chicago College of Medicine and Surg.	(1913)	75
Maryland College of Eclectic Medicine and Surg.	(1914)	75
New York Homeopathic Medical College	(1894)	75
Medical College of Ohio	(1906)	80.4
Vanderbilt University	(1912)	81.5

Rhode Island April Examination

Dr. B. U. Richards, secretary of the Rhode Island State Board of Health, reports the written and practical examination held at Providence, April 3-4, 1919. The examination covered 7 subjects, and included 70 questions. An average of 80 per cent. was required to pass. Of the 7 candidates examined, 3 passed and 4 failed. The following colleges were represented.

College	Year Grad.	Per Cent.
PASSED		
Yale University	(1915)	93.9
Tufts College	(1916)	83.7
University of Vermont	(1911)	89.5
FAILED		
University of Maryland	(1917)	75.7
Tufts College	(1917)	78.2
College of Physicians and Surg. Memphis	(1911)	78.8
Laval University	(1912)	75.5

Book Notices

Notes on Pathological and Operative Obstetrics. By Lyle G. McNeile, M.D., Professor of Obstetrics, College of Physicians and Surgeons, Medical Department of the University of Southern California. Cloth. Price, $2. Pp. 221. Los Angeles: The Division of Obstetrics, College of Physicians and Surgeons, Medical Department of the University of Southern California, 1919.

The effort of the author has been to correlate "the essentials of pathologic obstetrics, presented in such a form as may, perhaps, be suitable for senior medical students, or for busy practitioners." This he has accomplished in a thorough manner. The book is apparently based on the published notes of the late Herbert M. Stowe, which the author has amplified and brought up to date. New subject matter has been added, especially on the topic of cesarean section, concerning which a criticism of his stand on repeated section might justly be made. "Once a cesarean, always a cesarean" has not become the accepted dogma, although McNeile adopts it.

A little more care might have corrected numerous typographic errors.

La Suspension dans le Traitement des Fractures. Appareils Anglo-Américans. Par P. Desfosses, Chirurgien de l'Hôpital brittannique de Paris et Charles-Robert, Ancien Interne des Hôpitaux de Paris. Préface de M. Pierre Duval. Paper. Price, 4 francs. Pp. 172, with illustrations. Paris: Masson et Cie, 1918.

Although this little monograph was written primarily for the army surgeon, the principles enunciated are as applicable to industrial accidents as they are to the accidents of war. The theme is the use of suspension in the treatment of fractures. The method of applying suspension, with traction, to suitable fractures of the upper and lower extremities, should it be thought desirable, is discussed with great care and illustrated profusely. The principle of the Thomas splint is made use of extensively and various modifications of the splint to meet the necessities of particular cases are clearly set forth.

Those who are handling fractures will find many useful suggestions in this little volume.

An Inquiry into the Medical Curriculum by the Edinburgh Pathological Club. Papers Contributed to the Inquiry and Report by the Pathological Club. Reprinted from the Edinburgh Medical Journal. Boards. Pp. 512. Edinburgh: W. Green & Son, 1919.

This volume is a reprint of a series of articles which appeared in the *Edinburgh Medical Journal* beginning January, 1918. The general topic was "The Training of the Student of Medicine." The series was completed in March, 1919. The reprint contains also the extensive discussions which followed the reading of the several articles before the Royal Medical Society and the Edinburgh Pathological Club. Seventy-two papers are included. There is also a report of the Pathological Club, giving an outline of the proposed courses of instruction in the various branches of the medical curriculum. This series of papers deserves a careful reading by all who are interested in the development of the curriculum in medical schools.

Medicolegal

Prescriptions Under Harrison Narcotic Drug Act

(Foreman v. United States (U. S.), 255 Fed. R. 621)

The United States Circuit Court of Appeals, Fourth Circuit, holds that an indictment was sufficient which charged in substance that the defendant did dispense, distribute and sell a derivative of opium to the persons named without a written order and not in the course of his professional practice. But the court reverses a judgment of conviction of defendant Foreman, on such an indictment, for error in the following instruction to the jury:

> And the court further charges you, as a matter of law, that the issuing of prescriptions by a registered physician to persons other than his patients, and in the course of his professional practice only, whereby they could procure and did procure the inhibited drugs, is a sale, a dispensing and distribution, of such drugs within the meaning of the act of Congress under which the accused is being prosecuted.

The court says that, resolving all conflicting testimony against the defendant, no direct sale, barter, exchange, or gift, and no dispensing or distribution that would denote participation in a sale, barter, exchange, or gift by him, was proved. He registered and paid the tax. Afterward he gave prescriptions for morphin and cocain to the persons named in the indictment, who were drug addicts, calling for such quantities of the drugs as to indicate that he was merely gratifying the craving of the addicts and that he was not seeking to cure them of the habit. The drugs were not furnished by the defendant. On the contrary, the prescriptions were carried by the recipients to different registered druggists and by them filled. There was no evidence that the defendant was interested in the business of any of the druggists, or had any arrangement to share the profits of the sales with them, or that he was agent for any druggist, or that he even knew where the prescriptions were to be carried. What the statute forbids is sale, barter, exchange, or gift, including such distribution and dispensing by a physician not in the course of his practice as would amount to a participation in a sale, barter, exchange, or gift. The mere issuance of a prescription by a physician to be filled by any druggist, without participation by the physician in the sale made under it, would not be a sale as charged in the indictment, or such distribution or dispensing as amounts to a sale. The instruction quoted was therefore erroneous.

Constitutionality of Harrison Narcotic Drug Act

(United States v. Doremus (U. S.), 39 Sup. Ct. R. 214)

The Supreme Court of the United States holds the Harrison Narcotic Drug Act to be constitutional, reversing a judgment of a district court in Texas which held Section 2 of the act unconstitutional for the reason that it was not a revenue measure, and was an invasion of the police power reserved to the states. The first count in the indictment charged in substance that the defendant, a physician, duly registered, and who had paid the tax required by the first section of the act, did unlawfully sell to one Ameris 500 one-sixth grain tablets of heroin, not in pursuance of a written order on a form issued on the blank furnished for that purpose by the commissioner of internal revenue. The second count charged that the defendant did unlawfully and knowingly sell, dispense and distribute to Ameris 500 one-sixth grain tablets of heroin not in the course of his regular professional practice and not for the treatment of any disease from which Ameris was suffering, but for the purpose of gratifying Ameris' appetite for the drug as a habitual user thereof.

The Supreme Court says that the act may not be declared unconstitutional because its effect may be to accomplish another purpose as well as the raising of revenue. If the legislation is within the taxing authority of Congress, that is sufficient to sustain it. Considering the full power of Congress over excise taxation the decisive question here is: Have the provisions in question any relation to the raising of revenue? That Congress might levy an excise tax on such dealers, and others who are named in Section 1 of the act, cannot be successfully disputed. The provisions of Section 2 aim to confine sales to registered dealers and to those dispensing the drugs as physicians, and to those who come to dealers with legitimate prescriptions of physicians. Congress, with full power over the subject, short of arbitrary and unreasonable action, which is not to be assumed, inserted these provisions in an act specifically providing for the raising of revenue. Considered of themselves, the Supreme Court thinks they tend to keep the traffic aboveboard and subject to inspection by those authorized to collect the revenue. They tend to diminish the opportunity of unauthorized persons to obtain the drugs and sell them clandestinely without paying the tax imposed by the federal law. This case well illustrates the possibility which may have induced Congress to insert the provisions limiting sales to registered dealers and requiring patients to obtain these drugs as a medicine from physicians on regular prescriptions. Ameris, being as the indictment charged, an addict, may not have used this great number of doses for himself. He might sell some to others without paying the tax; at least Congress may have deemed it wise to prevent such possible dealings because of their effect on the collection of the revenue. The Supreme Court cannot agree with the contention that the provisions of Section 2, controlling the disposition of these drugs in the ways described, can have nothing to do with facilitating the collection of the revenue, as it would be obliged to do if it were to declare this act beyond the power of Congress acting under its constitutional authority to impose excise taxes.

The Chief Justice and three other members of the Court dissent because of the opinion that the Court below correctly held the act of Congress, so far as it embraced the matters complained of, to be beyond the constitutional power of Congress to enact, because to such extent the statute was a mere attempt by Congress to exert a power not delegated, that is, the reserved police power of the states.

Answers to Questions on Harrison Narcotic Drug Act—What Not a Prescription

(Webb et al. v. United States (U. S.), 39 Sup. Ct. R. 217)

The Supreme Court of the United States says that this case came before it on a certificate from the Circuit Court of Appeals for the Sixth Circuit, from which certificate it appeared that Webb and one Goldbaum were convicted and sentenced in the District Court for the Western District of Tennessee on a charge of conspiracy to violate the Harrison Narcotic Law. The certificate stated that Webb was a practicing physician who had duly registered and paid the special tax as required by Section 1 of the act. Goldbaum was a retail druggist, and had also registered and paid such tax and kept all records required by the law. It was Webb's regular custom and practice to prescribe morphin for habitual users, on their application to him therefor. He furnished these "prescriptions," not after consideration of the applicant's individual case, and in such quantities and with such direction as, in his judgment, would tend to cure the habit, or as might be necessary or helpful in an attempt to break the habit, but with such consideration and rather in such quantities as the applicant desired for the sake of continuing his accustomed use. Goldbaum was familiar with such practice and habitually filled such prescriptions. Within a period of eleven months Goldbaum purchased from wholesalers thirty times as much morphin as was bought by the average retail druggist doing a larger general business, and he sold narcotic drugs in 6,500 instances. Webb regularly charged fifty cents for each so-called prescription, and within this period had furnished, and Goldbaum had filled, over 4,000 such prescriptions.

On these and other facts stated, the Circuit Court of Appeals propounded to the Supreme Court three questions:

> 1. Does the first sentence of Section 2 of the Harrison Act prohibit retail sales of morphin by druggists to persons who have no physician's prescription, who have no order blank therefor and who cannot obtain an order blank because not of the class to which such blanks are allowed to be issued?
>
> 2. If the answer to question one is in the affirmative, does this construction make unconstitutional the prohibition of such sale?
>
> 3. If a practicing and registered physician issues an order for morphin to a habitual user thereof, the order not being issued by him in

the course of professional treatment in the attempted cure of the habit, but being issued for the purpose of providing the user with morphin sufficient to keep him comfortable by maintaining his customary use, is such order a physician's prescription under exception (*b*) of Section 2?

The Supreme Court answers that what it has said of the construction and purpose of the act in *United States* v. *Doremus*, 39 Sup. Ct. R. 214, plainly requires that Question 1 should be answered in the affirmative. Question 2 should be answered in the negative for the reasons stated in the opinion in said case. As to Question 3—to call such an order for the use of morphin a physician's prescription would be so plain a perversion of meaning that no discussion of the subject is required. That question should be answered in the negative.

Registration and Tax Requirements of Harrison Act

(Blunt v. United States (U. S.), 255 Fed. R. 332)

The United States Circuit Court of Appeals, Seventh Circuit, in affirming a conviction of defendant Blunt, a physician, on a count that charged that he, as a dealer, unlawfully and feloniously sold to one Dean 2,000 grains of morphin sulphate, without having registered as a dealer and without having paid the special tax as such dealer, says that while the Harrison Narcotic Drug Act does not, in express words, require a separate registration and payment of tax as dealer and as physician, there is a clear differentiation between them as to the obligations imposed on them respectively under the act. They represent distinct classes; each class is required to pay the tax. And the combination of both occupations in one individual does not exempt him from payment of a separate tax as a dealer and as a physician. Section 3236 of the Revised Statutes of the United States, as a provision of existing law relating to special taxes, is expressly made applicable to the special tax imposed under Section 1. It provides that:

> Whenever more than one of the pursuits or occupations hereinafter described are carried on in the same place by the same person at the same time, except as hereinafter provided, the tax shall be paid for each according to the rates severally prescribed.

Furthermore, in accordance with the power vested in him under this Section 1, the commissioner of internal revenue, with the approval of the secretary of the treasury, made a regulation to the same effect, namely:

> Every person conducting more than one class or place of business or practicing more than one profession, or at more than one place, in which the narcotic drugs are sold, dispensed or given away, must register and pay the special tax for each profession and business separately, even though conducted at the same address, and separate records must be kept under each registration.

"A sale, dispensing or distribution" is permitted to a dealer for a customer on a written prescription; but only "a dispensing or distribution" is allowed to a physician treating a patient, and then only in the course of his professional practice.

A portion of Article 10 of the Revised Regulations of the Treasury Department, as of May 4, 1916, contained in Internal Revenue Regulations, No. 35, reads:

> A physician, dentist, or veterinary surgeon may not engage in the business of selling narcotic drugs unless he is a registered dealer, authorized by the state laws to engage in such business. Additional registration is not required, however, when narcotic drugs are sold to a patient on whom a physician, dentist, or veterinary surgeon is in personal attendance.

These sentences are to be construed in the light both of Article 1 and of that part of Article 10 immediately preceding the quoted sentences. So construed, the regulations clearly require a physician who acts as a dealer to register as such; but a sale to one in the course of his personal attendance on him as a physician does not necessitate registration as a dealer.

The sale here contemplated is a sale by him not as a dealer but as a physician; instead of "dispensing, distributing or administering" a dose of the narcotic as a part of his medical service, without a separate charge therefor, it may be that in some places physicians are accustomed to charge specifically therefor. While this might well be deemed a dispensing, yet as it could be held to be a sale, the regulations out of abundant caution provide that in such a case, doubtless because the physician is not then acting as a dealer, no additional registration is required.

In the instant case, however, the indictment charged and the evidence abundantly proved that, though the purchaser was registered as a patient, the sale was made to him by the defendant acting as a dealer, and not as a physician in personal attendance, administering or dispensing the drug as part of the professional service.

Social Medicine, Medical Economics and Miscellany

The Russell Sage Institute of Pathology

The Russell Sage Institute of Pathology was founded in 1907 by Dr. Theodore C. Janeway through funds obtained by him from Mrs. Russell Sage. The first president of the board of directors was Dr. E. G. Janeway, who held office until his death in 1910. Associated with the Janeways from the beginning were Drs. D. Bryson Delavan, Simon Flexner and Graham Lusk, as directors. On the death of Dr. E. G. Janeway, Dr. Lafayette B. Mendel was elected in his stead; and on the death of Dr. T. C. Janeway, in 1918, Dr. E. F. Du Bois was chosen to fill the vacancy.

The institute was originally located (1907-1912) at the New York City Hospital and the New York City Home, with Dr. Horst Oertel as scientific director. In 1912, the institute was transferred to Bellevue Hospital, Graham Lusk having been appointed scientific director, and Dr. Eugene F. Du Bois, medical director of the reorganized institute. Dr. F. C. Gephart became chemist to the institute.

The construction of a respiration calorimeter of the Atwater-Rosa type by the skilled mechanics, Messrs. Soderstrom and Riche, achieved an instrument of such accuracy that the hourly heat production of an individual, as directly measured, agreed within a slight variation with the calculation of the amount of heat as estimated from the quantity of oxygen absorbed. This apparatus was the first accurate respiration calorimeter established in any hospital. The work at first concerned itself with the establishment of a standard of measurement of the basal metabolism of normal persons from youth to old age, and the divergence from this standard of metabolism which was induced by food. In association with Dr. Warren Coleman, the metabolism during typhoid fever was exhaustively studied. Dr. Francis W. Peabody of Boston visited the institute and was associated with the study of patients with cardiac and renal disease. Dr. Frederic M. Allen of the Rockefeller Institute contributed to the extensive metabolism studies on diabetes. Dr. J. H. Means of the Massachusetts General Hospital aided in the work concerning the effect of radium therapy on lymphatic leukemia, and concerning the stimulating effect of caffein on normal metabolism. To these may be added the extensive investigation into the nature of the metabolism of exophthalmic goiter by Du Bois and into the metabolism in malarial fever by Drs. D. P. Barr and Du Bois. In the last described paper, the twenty-eighth and the one last published in the series entitled "Clinical Calorimetry," appearing in the *Archives of Internal Medicine*, it was announced that the heat loss from the body at the onset and during the chill remained unchanged from the level determined before the chill, and that the extra heat produced by the muscular contractions during the chill was retained in the body and was the immediate cause of the rise of body temperature.

The beginning of the war brought the work of the institute to an abrupt close, and there remain a few unpublished papers and some uncompleted work on the nature of night sweats in tuberculosis.

Before the war it had been arranged to open the institute in October, 1917, with Dr. Homer F. Swift as scientific director, who was also to have been director of medicine on the Cornell division of Bellevue Hospital. Associated with him were to have been Drs. W. W. Palmer, J. P. Peters, Jr., and

D. P. Barr. The project constituted an attempt to demonstrate the feasibility of establishing a great clinic based on medical research in connection with the largest municipal hospital in the country.

It is of happy augury for the future of American medicine that Col. Homer F. Swift, who is well known for his work in France on trench fever and who is now chief consulting physician to our army of occupation with headquarters at Coblenz, will return to take charge of the Russell Sage Institute in the capacity of scientific director, and that both Drs. Peters and Barr have already returned from France and have taken up the work. It is with grateful appreciation that one recognizes that the good that Mrs. Sage has done lives after her and witnesses the beneficent influence of her lifelong and often expressed desire to "relieve the sufferings and advance the welfare of mankind."

Study of Infant Mortality in Brockton

Brockton, Mass., was selected as the fifth unit in the studies of infant mortality being conducted by the National Children's Bureau because it is an industrial city with an infant mortality rate notably lower than the average rate for the registration area, and because it is a city of a single industry, the shoe industry, whose skilled operatives are employed at comparatively high wages, and trade union conditions prevail. The general death rate has shown a steady decrease from year to year. From 1910 to 1913, inclusive, Brockton had the lowest death rate of those cities of the state with a population of not less than 50,000; and from 1901 to 1910, inclusive, it had the lowest average annual death rate in cities of this group. The city also has a higher percentage of children in the high schools than other cities of the state of its class. Of the 1,247 registered births in the study, thirty-seven, or 3 per cent., were stillbirths. The deaths among the live-born infants numbered 117, giving an infant mortality rate of 96.7 for the year studied, Nov. 1, 1912, to Oct. 31, 1913. Nearly half the deaths occurred in the first month, and as many before the end of the first day as between the ages of 6 and 12 months; one third occurred in the first week, and more than one fifth before the infants were 1 day old. The number of stillbirths compares favorably with other towns, and is lower than that of some cities. The preponderance of early deaths from causes tabulated as diseases peculiar to early infancy, premature birth, congenital debility and injuries at birth, and the stillbirths, would point to the importance of prenatal care in their prevention. All but 19.7 per cent. of the infants who survived long enough to be fed at all were breast fed wholly or partially for some period of the first nine months of life; but of these, the number breast fed surviving by months from one to nine dwindled from 78.5 in the first month to 33.2 in the ninth. Deaths by months among 1,000 survivors compared between breast fed and artificially fed infants showed for the former during the first month 17.3 and for the latter, 30. This dwindled to 2.7 for the former and 5.2 for the latter during the period including the tenth, eleventh and twelfth months. As is usually the case, artificial feeding was practiced more extensively among native-born mothers. The economic status of the family, whether the mother worked or not, the diminution of income by slack time or illness, number in family, etc., were all found to be factors affecting the infant mortality. Civic conditions, such as milk and water supplies, sewage and garbage disposal, cleanliness of streets, housing, and smoke nuisance, were above the average, or at least in a satisfactory state. Alcohol was not a prominent factor in morbidity, as Brockton had a no-license law. The conclusion of the report is that while the infant mortality rate for Brockton was low for the period named as compared with other cities of like population under similar climatic conditions, owing to the high wages paid and the intelligence of the workers, and the fact that very few mothers were gainfully employed away from home, as well as to the generally good municipal sanitation, yet the rate as compared with that of other cities of similar size and general type of population does not seem to be commensurate with the advantages enjoyed.

*Treatment of Acute Lung Abscess by Artificial Pneumothorax. B. Goldberg, and M. Biesenthal, Chicago.—p. 169.
Treatment of Tuberculous Cervical Adenitis. W. R. Abbott, Springfield.—p. 175.

Complement Fixation Reaction in Tuberculosis.—Lewis reports the results of studies that aimed primarily to determine, if possible, the lack of harmony that characterized the experience of different workers in the application of the complement fixation tests to tuberculosis. Lewis' investigations dealt mainly with such matters as the reaction time, the measure of completely bound complement, and titration against the antigen. He confirms the observations of others that certain tuberculous individuals give strong deviation reaction, while others entirely fail to react and certain apparently wholly normal persons also give strong reactions. His most important practical conclusion is that the numerical relations are such as to make it unsafe to apply the reaction to the diagnosis of tuberculosis, except as a matter of the most limited confirmatory interest. Methods hitherto applied in making the test have inherent defects that seriously impair its significance; but these have been remedied to a considerable extent by increasing the time of primary incubation or "period of fixation" to four hours and by employing several quantities of either complement or antigen simultaneously. By adding an equal quantity of glycerin the deviating qualities of tuberculous serums are reasonably well preserved, so that a temporary standard for the determination of the qualities of antigen may be established.

Influence of Protein Intoxication on Tuberculous Infection.—Krause and Willis continued their studies on whether infection with tubercle bacilli or already present tuberculous infection is modified by acute or chronic protein intoxication. Guinea-pigs that received continued and repeated infections of (homologous) tuberculo-protein and (heterologous) egg-white protein before infection were apparently less resistant to infection. After infection is established the repeated infections of heterologous protein (egg-white) did not appreciably influence the course of the infection. Repeated anaphylactic shock under the same conditions had no apparent influence on an already established infection. In the absence of specific tubercle the most intensive and frequently repeated application of tuberculo-protein failed to render the animals cutaneously hypersensitive. If tubercle was present, the repeated applications of heterologous protein (egg-white) had no effect on the cutaneous hypersensitiveness that had been produced by the tuberculous infection.

Skin Sensitiveness to Tuberculin During Influenza.—Bloomfield and Mateer have employed the cutaneous (Pirquet) tuberculin test on patients at the height and after the subsidence of acute influenza. Of nineteen cases so studied, all but one patient showed a complete inhibition of reactive capacity during the manifestation of symptoms of acute influenza. During convalescence reactivity returned in 89.4 per cent. of the cases. The return to maximum reactivity was gradual in most cases, as shown by successive tests. In ten of the cases, the first test made during the febrile stage was negative, while during convalescence it became markedly positive. In six, in which the temperature became normal on the day on which the test was done, or on the following day, there was a very slight reaction; and these were regarded as delayed and depressed reactions, since all these individuals later responded with prompt and strongly positive reactions.

Artificial Pneumothorax Treatment of Acute Lung Abscess.—Golberg and Biesenthal believe that this method offers distinctly better advantage of success than the ordinary medical and surgical procedures heretofore used. Collecting the sixteen cases thus far reported as having been treated by artificial pneumothorax, including the three in their own experience, the authors find that 75 per cent. of the patients have made a complete recovery, 12 per cent. have been improved, and 12 per cent. have died.

Case of Successfully Operated Wound of Heart. E. G. Crabtree, Boston.—p. 588.

Chordoma.—Daland cites the case of a woman, aged 30, who complained of hoarseness, headache and a swelling in the right side of the neck. Three years ago the patient suddenly became hoarse without any apparent cause. The hoarseness cleared up in three days and there was no further trouble for a year. Two years ago a severe headache developed and the hoarseness reappeared. Two days after manipulation by an osteopath a swelling appeared in the right postcervical region. Tinnitus was noticed in the right ear soon after this and it has persisted. One year ago the patient's right clavicle became more prominent and she was unable to lift her arm laterally over her head. The mass in the right postcervical region has increased in size and has at times been painful. Recently she has been nauseated frequently and has vomited occasionally, more in the morning. Behind and slightly below the right ear, extending downward on the neck and backward nearly to the median line was a mass the size of a hen's egg, firm, non-tender, and nonfluctuant. An incision was made over the growth and colloidlike material curetted out with free hemorrhage. Seven months after the operation the patient stated that her headaches had enirely disappeared. There is a recurrence of the mass in her neck and she has some pain. Microscopic sections from the tumor contained cells which tend to differentiate like those of the notochord. Much of its structure is of the embryonic type and resembles mucous connective tissue. Daland says that seventeen cases of tumors of notochordal tissue which have given clinical symptoms are recorded: Twelve of these are over the upper end and five over the lower end of the neural canal. Two of the seventeen patients have been successfully operated on. Death followed in the others. The case cited is the seventeenth case of chordoma. Although showing involvement of several cranial nerves, the patient is still alive.

Method of Hemostasis in Resecting Portions of Liver.—While removing a tumor from the liver hemorrhage was controlled by Freeman by tying off the part to be removed by means of two long narrow strips of fascia lata, like pieces of tape. These strips were first pulled directly through the substance of the liver, from behind forward, with a pair of long alligator forceps, and their respective ends tied very tightly around the hepatic substance to either side. The growth was then cut away, well within healthy liver tissue, without the slightest difficulty or bleeding, in spite of the great thickness of the hepatic stump.

*Case of Bilateral (Double) Spontaneous Pneumothorax. E. A. Gray, Chicago.—p. 252.

Case of Bilateral (Double) Spontaneous Pneumothorax.—Gray reports the case of a man, aged 32 years, a victim of pulmonary tuberculosis who had a violent coughing spell, marked by a sudden pain in the right side and followed shortly by dyspnea. The diagnosis of spontaneous pneumothorax, right, was made. Aspiration of the right chest was immediately done and 2,000 c.c. of air withdrawn; the patient promptly rallied and became comfortable. Ten hours later, it became necessary to aspirate again. The escape of air from the lung increased and it was soon found necessary to aspirate at shorter intervals. Because of extensive disease of the left, lung, the latter did not contain enough aerating tissue to sustain life. Nevertheless, to determine the point, the trocar was allowed to remain open in the chest wall on the pneumothorax side, creating, in effect, an open pneumothorax. Within a very few minutes the patient showed great distress and aspiration was done. Effusion soon appeared and this, in a short time, showed infection. The amount of fluid soon became great and required frequent aspiration. Air began to diminish in quantity. On the fourteenth day a fistula occurred in a needle track. The skin opening was fortunately trapped and, while coughing, expelled air and fluid (pus and seropus), there was no inhalation through the sinus. It was now decided to attempt to bring the lung down; to this end, continuous siphon drainage was established, with the result that, by June 18 (the twenty-third day) breath sounds were heard over the right upper lobe as far down as the third rib, and respiration became much easier and the patient was able to lie on the pneumothorax side. On the seventh day an extensive emphysema occurred and involved the chest, abdomen, scrotum, penis, neck and face. June 19 the patient complained of shortness of breath; aspiration of the right chest was done, but little relief was afforded. The trocar found the base of the lung in the fourth space. Examination of the left lung showed diminution of breath sounds. June 20 the patient was found to be much worse. While fair respiration was being performed by the right lung, the left lung presented no sounds whatever. The patient complained of some pain in the left lung, but of very little dyspnea. Aspiration of the left chest relieved the patient of 1,800 c.c. air, but did not improve the general condition. He was comfortable until his death, which occurred twenty-four hours after the second rupture.

War Neuroses. C. D. Humes, U. S. A.—p. 123.
Medical Empiricism and Pathology of Chronic Head and Throat Infections. O. C. Breitenbach, Columbus, Ind.—p. 125.
*Club Feet. H. R. Allen, Indianapolis.—p. 130.
Bacillus Fusiformis Infection; Report of Case. S. R. Edwards, Indianapolis.—p. 132.

Treatment of Club Feet.—As to the treatment of club feet, Allen says that he would not under any conditions ever touch a bone with any kind of a surgical instrument, nor would he make a skin incision longer than one-eighth of an inch, nor use a Thomas wrench. The treatment he employs consists of surgery and proper bracing. The adduction and pes cavus are first reduced by cutting the flexor brevis and fascia, if necessary, then forcibly shred or tear all other soft tissues resisting the extreme limits of normal abduction and planus positions. The second step is to cut obliquely the tendo-achilles and then forcibly convert the equino-varus into a valgo-calcaneous position. If the surgery and manipulation have been thorough and complete, then the little finger will easily convert the adducto-cavo-varo-equinus into an extreme position of abducto-plana-valgo-calcaneus and then but little resistance will be encountered in retaining this position. The next step is the application of braces. There are two kinds of braces, and two periods for using them. The first brace is the retention brace. It is used both day and night at the beginning, being removed for bathing and massage. The period of wearing braces varies. People between 35 and 60 years wear braces for an entire year. Younger patients wear them a shorter time. The retention brace is worn day and night until the foot shows no tendency to return to its original deformity, after being absolutely unbraced for a number of hours. When this point is reached, the walking brace may be employed during the day and the retention brace used only at night. The retention brace must hold the foot and femur about parallel. The tibia and femur should be so flexed on each other that the papliteal angle thus formed is considerably less than a right angle. The brace must also secure the exact counterparts of each of the original deformities. It is also important to understand that in order to produce ultimately a normal foot with normal ranges of movement that these extreme normal ranges must be secured during the process of correction. The time necessary for operation and application of the retention brace is usually ten or twelve minutes.

Antibodies in Fetus.—This paper is confined to a study of the natural antibodies of swine embryos. Included are lysins, complement and bacterial opsonins. Sherman found that in the youngest embryos complement and lysins are inappreciable. Opsonins were present but averaged only 0.04 as measured by the opsonic index. Complement and opsonins increase as the age of the fetus increases. Lysins do not appear to increase. In the amniotic fluids complement is only occasionally found; lysins and opsonins resemble closely those of the fetal serums. The conclusions of Polano and Goldmann from their work, respectively, on antitoxins and vital stains, that the amnion has a selective secretory action, seems to be unwarranted. The theory of the transudation of the amniotic fluid from the maternal serum is untenable. The amniotic fluid is probably derived almost exclusively under normal conditions as a transudation from the cord and as a secretion from the surface of the fetus. In the allantoic fluids complement was found only in the younger embryos. Lysins are found more prevalent in the earlier fluids but to a small extent also in the later.

Vaccines of Partial Tension Streptococci.—From a series of thirty-two cases of rather diverse nature partial tension streptococci were isolated by Oliver and Perkins. In one case each of asthma, pyorrhea, chorea, uterine infection and two cases of "cold abscess" growth was obtained only at partial tension. In one of the cases of "cold abscess" isolation of a very minute streptococcus was effected only by growth in an atmosphere of diminished oxygen from which the respiratory carbon dioxid was removed. In the remaining twenty-six cases, the relative luxuriance of growth at partial tension was in contrast to the meager growth obtained aerobically and, in certain cases, anaerobically. By the use of the partial tension method sufficient growth was obtained usually within twenty-four hours and never later than forty-eight hours, to allow of the preparation of an autogenous vaccine. In none of the seventeen cases in which vaccines were prepared was sufficient growth obtained aerobically or anaerobically within forty-eight hours to warrant the preparation of a vaccine.

Antigens in Wassermann Reaction.—The antigens studied by Ruediger were alcoholic extract of human heart muscle; alcoholic extract of syphilitic fetal liver; alcoholic extract of dog heart muscle; acetone insoluble antigen of dog heart muscle; alcoholic extract of sheep heart muscle and acetone insoluble antigen of sheep heart muscle. He found that antigen diluted with the salt solution slowly so as to give an opalescent solution gave many more positive results with the Wassermann test than did antigen which was diluted rapidly enough to give a clear solution. Adding the antigen to the human serum before the complement gave results identical with those obtained when the complement was added before the antigen. Antigen supposed to be alcoholic extract of syphilitic fetal liver and antigen prepared from dog heart gave many more positive results than did alcoholic extract of human heart. As no other signs or symptoms of syphilis could be detected these were considered false positive results, and these antigens were discarded as being unreliable. Antigen prepared from sheep heart gave results almost identical with those given by antigen prepared from human heart. Ruediger is convinced that the glycerol added to the human serum cannot be held responsible for the false positive results obtained. Previous absorption of the natural antidog amboceptor from the human serums did not eliminate the false positive results.

Spiral Bodies in Bacterial Cultures.—Spiral bodies resembling spirochetes were found by Koga and Otsubo in anaerobic cultures of various bacteria cultivated in the plasma-ascites medium, Noguchi's ascites-agar and Shimamine's horse serum medium. They conclude that the spiral bodies are nothing more than an unusual development of the flagella or parts of the bacterial bodies. The spiral bodies seem to be identical with Noguchi's involuted forms of Treponema macrodentium. It is suggested by the authors that it is necessary to pay special attention to motility, stainability and the pure cultivation in any study of spirochetes, when associated with other bacteria. Morphology alone is not in these cases reliable. It is further suggested that this method may be applied in the search for flagella. They have discovered the presence of flagella in B. mallei, which had been considered to have no flagellum.

Bacteria of Prostate and Adenoma.—From a series of thirty-nine cases organisms have been isolated by Rosen. The colon group of organisms was the commonest found; no one organism was found specific to the gland; not once was the gonococcus isolated. The history of the cases in this series shows that persons with a negative record as to gonococcus infection to be as susceptible to prostatic hypertrophy as those with infection. Rosen is convinced that the significance of the bacteria isolated from the prostate gland and the rôle that they may play in prostatic hypertrophy, if any (other than that they may be secondary invaders), cannot be determined from this investigation.

Isolation of Influenza Bacillus.—By the employment of gentian violet blood agar Bernstein and Loewe found the isolation of the influenza bacillus to be comparatively easy. The use of this medium gives a much higher percentage of positive results than plain blood agar. Agar was prepared with a H ion of 7.1 and a gentian-violet content of 1 : 5,000—taking a concentrated alcoholic solution of the dye as unity.

Effect of Cocain Hydrochlorid on CO_2 Production.—The results of Niwa's experiments support the statement that the local anesthetics, cocain hydrochlorid, affects the metabolism of the mixed nerve in exactly the same manner as do general anesthetics, namely, primary stimulation by a weaker concentration, and subsequent diminution of the CO_2 production by a higher concentration. These facts demonstrate that there is a close relationship between the rate of nerve metabolism and the state of excitability of the nerve, and suggest that anesthesia in general is probably brought about by interference with the tissue metabolism.

*Action of Viburnum Prunifolium. B. H. Hager and F. C. Becht, Chicago.—p. 61.

Mechanism of Absorption of Mustard Gas by Skin.—The experimental data obtained by Smith et al. indicate that mustard gas is first adsorbed by some element on or immediately adjacent to the skin surface. While a portion of the mustard passes rapidly inward to a point from which it cannot subsequently be removed, the greater portion remains on or near the surface for a considerable period, a proof of which is that it may be removed even after ten or fifteen minutes by persistent washing with organic solvents. The amount of mustard passing into the atmosphere from an exposed surface far exceeds the amount passing into the inner strata of the skin. This loss is very great at first and is still demonstrable after forty-five minutes. The time of exposure necessary to produce a positive reaction bears a definite relation to concentration and varies for different individuals. A resistant skin adsorbs far more gas than a sensitive skin, and gas may be withdrawn from the latter by the former. The difference in sensitivity of different skins is due principally to difference in saturation adsorptive capacity. The intracellular threshold concentration of gas required to produce pathologic changes in the skin is approximately the same in resistant and sensitive individauls.

Action of Local Anesthetics on Striated Muscle.—The action of a large number of local anesthetics on excised skeletal muscles of the frog and the rat was studied by Kubota and Macht. It was found that all of the substances studied depressed the excitability and the contractility of striated muscle and caused a quicker onset of fatigue. No primary stimulating effect was noted after the exhibition of even very small doses of cocain or local anesthetics. Of the decomposition products of cocain, ecgonin was found to be a powerful depressant, while benzoyal ecognin was only very slightly depressant in its action, and sodium benzoate and methyl alcohol produced practically no effect. The stimulating effect of cocain on muscular work, therefore, cannot be due to its peripheral action on the muscles themselves, but must be ascribed to a central action.

Action of Viburnum Prunifolium.—None of the preparations of viburnum prunifolium, which Hager and Becht tested markedly affected uterine movements, in either a positive or negative direction. Therefore, they believe that the assertion is borne out by their experiments that as compared with pilocarpin and pituitary extract preparations of viburnum prunifolium must be considered an indifferent drug with no specific action on the uterus. They are convinced that no uniform pharmacologic effect can be ascribed to the drug, for while a stimulation may seem evident at one time, a similar dose under the same conditions produces an apparent inhibition or no perceptible change whatever. The change in the contractions of the uterus which sometimes occur on the addition of an extract of the viburnum prunifolium bark are so slight that the changes may be explained as having been produced reflexly through manipulation of the animal during injection or by the alcohol which holds the drug in solution.

Experiments to Produce Human Tuberculosis in Fish.—For a period of over three years, Rosenberger conducted experiments trying to determine if tuberculosis could be produced in fish with the human tubercle bacillus by raising the temperature of the water to or near the body temperature of man. In certain parts of the world the eating of raw fish is quite common, and it occurred to Rosenberger that this might be one of the means of the dissemination of the disease. During the entire period of experimentation in all of the spreads studied both from the sediment of the water and the feces of the fish, tubercle bacilli were always demonstrable, although in gradually decreasing numbers. It would seem that the time (three years), mostly at ordinary room temperature, and for several months from 30 to 33 C., was sufficient for infection to have taken place in these fish, and in not one fish was the least suggestion of a tubercle found, except a seemingly increased number of small round cells in the submucosa of the intestinal canal. Rosenberger made histologic studies of a number of control fish of the same variety as those experimented on, and in all of them great numbers of small round cells were observed in the submucosa of the intestines.

Epidemic Central or Basilar Encephalitis.—Of fourteen cases of this disease seen by Sachs, five proved fatal. All of these were bulbar cases. Some patients with bulbar symptoms are on the way to recovery. The cases are cited in detail.

Congenital Pyloric Stenosis.—Peple has devised a special table for operating on babies. It is made of wood and is twenty-eight inches long, ten inches wide, and eight inches high. It contains a drawer which can be filled with hot water bags to supply and maintain heat without any danger of burning. It has a headpiece that drops back at any desired angle, and a screen to keep the anesthetist well out of the way. It is fastened, by bandages passing through its lower rim, to any operating-table, making it perfectly steady and allowing it to follow the big table in Trendelenburg or any other desired position. Slots and holes are cut in its upper surface, so that the hands and thighs may be securely fastened. These also allow the heat from below to come up under the covers to maintain an even temperature. The height of the table raises the surface of the abdomen about as high as the adult's would be. Special little blankets are used to wrap the chest and legs, and little covers and sheets are made to suit the baby; with a special set of little instruments, needles and sutures, everything is brought into proper proportion.

Treatment of Lepers with Gynecardate of Soda "A".—Muir reports on the condition of thirty patients whose cases were recorded previously and cites twenty-three new cases in which he used gynecardate of soda "A". As sodium gynecardate "A" led to destruction of the veins in several cases it was found necessary to give sodium morrhuate intramuscularly. There was not such rapid progress made in the clearing up of anesthetic patches with the morrhuate, but the nodular patches made equally rapid progress. In some cases, over-dosage led to a very marked febrile reaction, accompanied by the formation of pustules and, later, of sores on the limbs and a recrudescence of anesthesia. This sudden return of anesthesia was in cases that had made specially rapid progress before. The rapid progress made at first in several cases was followed later by slower, but still steady, progress towards recovery. Early cases healed up rapidly, especially in children with intravenous injections of sodium gynecardate "A" solution. Sodium morrhuate is not nearly so destructive to the veins. To get the maximum of effect Muir recommends the following system of dosage: First week.—Sodium gynecardate "A" .5 c.c. intravenously, first day; sodium gynecardate "A" .25 c.c. plus sodium morrhuate .25 c.c. intravenously, third day; sodium morrhuate .5 c.c. intramuscularly, fifth day. Second week.—Sodium gynecardate "A" 1 c.c. intravenously, first day; sodium gynecardate "A" .5 c.c. plus sodium morrhuate .5 c.c. intravenously, third day; sodium morrhuate 1 c.c. intramuscularly, fifth day. In this way the dosage should be increased by .5 c.c. week by week up to 5 c.c., provided there be no marked febrile reaction or other danger signal. Where there is a marked febrile reaction the dose should be halved and again gradually raised, but kept at least 1 c.c. below the dose that produced the marked reaction. The injections should be continued for some months after symptoms have entirely disappeared.

Bacteriology of "Spanish Influenza."—In fifteen typical cases of epidemic influenza examined by Woutersz an organism was discovered which has not been described as yet. Of the fifteen patients seven recovered in from four to eight days; the remaining eight patients developed pneumonia very early in the illness and died in from three to five days. Of the seven patients who recovered, the sputa of six were examined at the height of the illness; in the seventh case the sputum was not examined till the eleventh day after recovery. In all these cases the sputum was found to be teeming with moderate sized, plague-like bacilli. After a month's convalescence the organisms were not found in the sputum. Similar organisms to those found in the sputum were present in the heart-blood, spleen, lungs, and kidneys of the fatal cases. Smears stained with dilute (1 in 10) carbolfuchsin showed a large number of bacilli not unlike *B. pestis*, but perhaps a little more regular in shape and more pointed. Pfeiffer's *B. influenzae* could not be identified in the smears from sputum or the post-mortem material. Cultures made on serum agar, blood agar, and haemoglobin (Deschien's) agar failed to give a growth of Pfeiffer's bacillus. On the other hand, the plague-like organism was always present in cultures. The organism is a rather short bacillus with a tendency to polar staining; a very noticeable character is its pleomorphism, especially when grown in liquid media, although direct preparations from the tissues also show it. Cultures on agar-agar show short, coccoid forms, and at times the organism looks very like a diplococcus. Longer forms are met with in broth cultures. Diplobacilli are very common. Smears from heart-blood show a well-defined capsule, but it is not as a rule met with in smears from the spleen and other organs. The capsule tends to disappear on cultivation in solid media, though milk cultures almost always show it. No flagella or spores were demonstrated. True motility was not observed. The organism is gram-negative, and stains very readily with all the usual laboratory stains. It is acid-fast. The organism grows aerobically but it is also a facultative anaerobe. The organism isolated freshly from the human body is highly pathogenic for rabbits, guinea-pigs, and rats. Grown for several generations on artificial media, however, it rapidly loses its virulence.

Operation for Piles.—The operation described by Foulkes is really that called "Robert Jones's," by Burghard, varied by the use of a modification of the interlocking ligature previously described by the author in 1912.

Unusual Case of Hydrophobia.—A male, aged 25, was bitten on the right thigh, three punctures, about October 5, 1918, by his own dog, which had been bitten by a stray dog about a month before. A cow, an ass, a dog, and the man's wife were bitten the same day as he was bitten. Of these, the dog was killed within a few days, the wife died from hydrophobia about a month and a half after having been bitten, and the cow and the ass died a few days later. The patient's wounds healed. He continued his occupation until the morning of February 4, 1919, about four months after his bite, when he felt a difficulty in swallowing and in breathing. He died on the twelfth, nearly nine days later, which Cornwall points out is an unusually long time for the disease to last.

*Amebic Abscess of Brain: Following Amebic Abscess of Liver. F. L. Armitage.—p. 69.

Amebic Abscess of Brain Following Amebic Abscess of Liver.—Dysenteric abscess of the brain supervene, as a general rule during or following a liver abscess, and the condition is found most commonly in those regions where amebic dysentery is endemic. Forty-eight cases are recorded to date. The amebas are carried from the liver by the circulation via the circle of Willis to the brain, where successive lesions are evolved in the cerebral tissue. The case seen by Armitage is one recorded by Stout and Fenwick. The patient, aged 35, was admitted to the hospital, with a diagnosis of "gallstones," and a history of frequent rigors, jaundice, pain in the region of the gallbladder and evening rise of temperature to 103 F. There a diagnosis of hepatic abscess was made. The patient was operated on, and an abscess evacuated. The liver abscess pus showed many actively motile *Endamebae histolyticae*. About six weeks afterward mental symptoms were noted, such as drowsiness and listlessness. There was no pain, and on the whole he slept fairly well, but was frequently disturbed by a troublesome cough. The pulse varied from day to day, being fairly good at times, at others becoming very weak, and he was put on strychnin and pituitary extract. The urine and feces continued to be passed involuntarily, and remained so throughout the rest of his illness. His mental condition improved somewhat, he spoke rationally, and was usually cheerful and bright. A troublesome hiccup developed during the last three days of his illness, and on the day prior to his death he complained of occasional headache, which apparently, however, was not severe. The temperature during the last fortnight was usually about 101 F., the highest being 102 F. There were no rigors and no ocular or localizing symptoms indicating brain abscess. The patient died fifteen days after the onset of cerebral symptoms. At the necropsy an abscess of size of pigeon's egg was found in the lower inner portion of the right frontal lobe extending into right ventricle, and containing thin yellow pus. There was an area of softening in the brain around and localized basal meningitis in that area. Motile endamebas were found in the softened tissue surrounding the pus proper.

*The Argyll Robertson Sign in Prognosis. E. Rasquin and B. Dujardin.—p. 26.
War Mental Disturbances. A. Leroy.—p. 40.

Lethargic Encephalitis.—Burger and Focquet declare that to date the clinical picture known as lethargic encephalitis is confused, the causal agent unknown, and the pathologic anatomic basis not well defined. It was first described in Paris and England in March, 1918, but epidemics had been recorded at Tübingen in 1712, in Italy in 1890, and at Vienna in 1917. The death rate is about 33 per cent. They describe a case in the maréchal des logis, who was found unconscious on the street, apparently in the deep slumber of drunkenness. He slept calmly the next day till he roused and complained of severe headache in the right temple, and ptosis of the right eyelid and divergent strabismus were also noted. He soon dropped to sleep again. Jacksonian epilepsy developed in the course of the disease, which proved fatal the thirteenth day. Lumbar puncture showed a hemorrhagic process but no bacteria could be cultivated from the fluid.

The Argyll Robertson Sign.—Rasquin and Dujardin assert that the discovery of the Argyll Robertson sign calls at once for making out the balance sheet as regards syphilis. It may be the only sign of the disease and the patient may not be aware that he has it and may feel perfectly well. Nevertheless he must be told of the danger in which he stands, and the urgent necessity for treatment must be impressed on him as the only chance for him to escape some severe nervous affection, general paralysis, for example. The balance sheet can be drawn with great precision nowadays by the data obtained from examination of the blood, spinal fluid and the reaction to luetin. We can thus form a kind of biologic formula which can be compared with the typical formulas of the principal syphilitic nervous affections, and thus foretells the outcome. If the Bordet-Wassermann test of the blood is negative, reactivation must be tried. 'If this is negative, then lumbar puncture must be done, and only when all of these give a negative response are we justified in keeping the patient merely under surveillance. When the findings in the spinal fluid are seen to be exactly like those with grave nervous affections, the patient becomes convinced of the desirability of treatment. These old forms of syphilis are often very slow in responding to treatment, even quite active. As the reactions return to normal under treatment, the patient will understand better and will submit more docilely to our therapeutic efforts. By comparing the biologic formulas from time to time we can supervise conditions as they improve and further convince the patient of the wisdom of thorough treatment.

Wounds of Large Vessels at Base of Neck. L. Sencert.—p. 101.
*Surgical Complications of Typhus. P. Moure and E. Sorrel.—p. 136.

Surgical Complications of Typhus.—Moure and Sorrel were at the French hospital at Jassy during the 1917 epidemic of typhus and of relapsing fever in Roumania. They were impressed by the frequency, after typhus, of nose, mouth and throat complications, of parotitis, of laryngeal and ocular complication, erysipelas and gangrene. In two soldiers, acute delirium with attempt at suicide, was almost the first symptom of the disease. The streptococcus was generally responsible for the complications which were usually subacute. The prognosis is generally grave as the patients are at such a low ebb of vitality. Prophylaxis must aim to ward off secondary infection, and general strengthening treatment is more important than local measures.

*Indemnization for Hysteric Accidents. R. Cruchet.—p. 147.
*Oxygen for Burns from Gassing. E. Rousseau and L. Devaux.—p. 149.

Pension for Hysteric Disability.—Cruchet recalls that in 1916 the Société de Neurologie voted that phenomena of hysteria, pure pithiatism, do not entitle a soldier to a special disability pension. This dictum was voted notwithstanding Pitres' objections, but time has confirmed these objections, and the society has had to capitulate. March 20, 1919, the society went on record as advocating discharge from the army and a special disability indemnity for this class of cases. The hysteric are diseased, and the examiner has only to determine the amount of real disability resulting. Pitres related that in the 503 cases at Bordeaux there was not a single instance of hospital contagion. He insisted that these cases should be regarded from the same standpoint as industrial accidents. The indemnity finally voted by the society was a sliding scale from zero to 20 per cent.

Treatment of Mustard Gas Burns.—Rousseau and Devaux had a lot of raw meat that had been exposed to mustard gas sent to their laboratory, and their tests on this material showed that nascent oxygen annulled the irritating properties of mustard gas, the "yperitis." Copious application of hydrogen dioxid proved effectual in treatment of gassed soldiers, suppressing the intense pain constantly and completely in less than ten hours, the pain subsiding by half in less than an hour, and the edema disappearing in less than six days and showing marked improvement in a few hours. Fats hold the mustard gas and form a barrier to the action of the nascent oxygen, hence salves should not be used.

*Tuberculosis of Tracheobronchial Glands. A. Dumas.—p. 180.
*Nervous Complications of Influenza. C. Maurice.—p. 187.

Fulminating Tuberculosis of Tracheobronchial Glands.—Dumas describes five typical cases of this unusual form of tuberculosis as he observed it in five African soldiers at Salonica. The men entered the hospital with the diagnosis of bronchitis and died in two or three months, necropsy showing tuberculous involvement of the mediastinal lymphatic system with secondary invasion of pleura and pericardium. Some of the glands broke down into a purulent focus while the lungs escaped almost entirely. The cases all proved rapidly fatal, none lasting for over three months. "Radioscopy differentiates the disease but the temperature determines the prognosis." The clinical picture is more like those observed in children than in adults, but even in children such a fulminating form is almost unknown, while it seems to be the rule in the blacks of the French colonies in Africa.

Nervous Complications of Influenza.—Maurice reviews the indications for treatment during convalescence for influenza, saying that this disease strikes electively the great sympathetic and the glands with an internal secretion which stimulate this nerve, that is, the thyroid and suprarenals. The nervous complications of influenza are thus traceable to the sympathetic nerve, as he explains in detail. Arsenic and strychnin combat this, but quinin is not indicated, as this, he says, is a *réducteur thyroïdien*. Calcium chlorid, about 2 gm. daily, will have a favorable action when the arsenic and strychnin have produced their *tonic* effect on nutrition and circulation. The calcium chlorid should be kept up for several weeks, combining epinephrin with it, about fifteen drops a day. Alcohol and the juice of raw meat should be avoided at first, while the thyrosympathetic asthenia is marked. Starchy foods, purées and cooked fruits reënforce the strychnin-arsenic medication with a tonic and remineralizing action. But later, wines and raw meats will aid in improving the state of the blood and the secretory activity of the glands. Phosphorus, eggs and milk he denounces as reducing thyroid functioning and the blood pressure. They will increase the *embarras gastrique,* he says, and benefit only in cases of a tendency to melancholia when there is a constitutionally high pressure. A change to the country, out of door life and peace of mind are the sovereign remedies for vegetative asthenia, and they should be imperatively ordered if other measures fail.

April 26, 1919, **9,** No. 17

The Teaching of Hydrology. G. Linossier.—p. 325.
*Treatment of Acute and Chronic Anaphylactic Disturbances. J. Danysz.—p. 329.
*Cancer of Rectum. R. Savignac.—p. 334.

Anaphylactic Skin, Gastro-Intestinal and Nervous Disturbances.—Danysz remarks that bacteriologists and clinicians are still at variance as to whether immunity and anaphylaxis are the result of reactions of a different or similar nature. He here reports some recent experiments and clinical experiences which throw more light on the nature and consequences of these reactions, and their bearing on certain digestive, cutaneous and nervous disturbances. The difference between the reaction to repeated injection of a toxin (anaphylaxis); and the reaction to repeated injection of any other antigen (immunity), is due he explains, to whether the mixture of toxin and antitoxin forms a precipitate or persists clear. If there is a precipitate and if the antigen was a virulent microbe, the reaction will be manifested both by immunity and by anaphylaxis; by anaphylaxis alone if the antigen is an albuminoid food substance. If no precipitate forms, the reaction will be manifested by antitoxic immunity without any phenomena of anaphylaxis.

He explains further that the production of antibodies in excess of what is needed is liable not only to fatigue the cells, but the continuous production of an excessive amount of antibodies may induce various chronic morbid conditions, digestive or respiratory disturbances, dermatoses, "rheumatism," etc. These various disturbances can be arrested only by checking the excessive production of antibodies which is keeping up a chronic anaphylaxis. This can be accomplished by the same means which abort an attack of acute anaphylaxis, namely, by Besredka's method of a preliminary injection of a minute dose of the antigen which in a larger dose would unleash the anaphylactic crisis. The same result can be realized by ingestion of a strong dose of alcohol or ether (Roux and Besredka); by ingestion of a small amount of peptone (Pagniez and Vallery-Radot); or by injection of a vasoconstricting drug (epinephrin, Milian). These reactions are not specific, but they answer the purpose, and the symptoms of chronic anaphylaxis can be cured by the same mechanism of injection or ingestion of nonspecific antigens.

In practical application of this principle, Danysz has treated 159 patients, including 103 with various gastro-intestinal disturbances, 2 with persisting neurasthenic insomnia, 9 with painful menstruation, 8 with asthma, 15 with psoriasis, 10 with other dermatoses and 12 epileptics. The antigen used in treatment was an emulsion made from the bacteria in the patient's stool or a similar hetero-emulsion. The intestinal flora in the pathologic cases always included bacilli that fermented saccharose and lactose, bacteria liquefying gelatin, and certain varieties of streptococci, diplococci and enterococci, so that Danysz recognized a uniform flora, as it were, and he found that the heteropreparations were usually as efficient as those of autogenous origin. Only in the cases of painful menstruation some patients proved refractory to the hetero-antigen but yielded at once to the auto-antigen. The benefit in epilepsy was always pronounced. One boy of 9 who had been having several seizures a day has had no return of them during the eight months to date. The doses were always small, never over 3 mg. in a beverage; for subcutaneous injection, a few hundredths of a milligram of dried microbe bodies of a constant weight.

He cultivates separately each of the microbes which grow on slanting gelose, and mixes the emulsions in the proportions in which they occur in the stool, sterilizes at 60 C. or boils up two or three times if there are spores. In the majority of cases the benefit was manifest from the very first, the patient saying, "I felt something like a chill all over, and then I felt very much better at once."

Palpation of the Rectum.—Savignac in extra large type urges to make a digital examination of the rectum in every case of hemorrhoids, even suspected, of pain in rectum or anus, and of diarrhea or constipation. This is the only and almost the infallible means to reveal cancer of the rectum, and possibly in its incipiency.

*Bone Grafts to Repair Gaps in Bones. P. Mauclaire.—p. 213.
*Leukocytosis in Infections. G. Audain.—p. 216.
Experimental Research on Hemorrhage. L. Binet.—p. 217.

Bone Grafts.—Mauclaire warns that a bone grafting operation should not be attempted until at least six months after the healing of a suppurating lesion. He found a small latent focus of osteitis in one case four months after apparently complete healing. The various technics that have been applied are reviewed and compared, and the results. In 128 cases of segmental grafts, complete success was realized in seventy-two. In his own twenty-four cases he has had eight successes, and explains that extraneous circumstances were responsible for some of the failures. If the graft is well nourished, it usually increases in size and the functional result is perfect. He prefers to introduce loosely the pointed ends of the graft into the marrow cavity of the long bone.

Leukocytosis in Infections.—Audain explains that when the infection is in an organ or tissue abounding in lymphoid elements, the mononuclear white cells are the pivot of the defense. With an organ or tissue poor in lymphoid elements (like the cellular tissue, lung or blood), the polynuclear is captain of the defensive forces. The difference between the number of polynuclears or mononuclears and the normal figure is an index of the conditions which determine the prognosis. Thousands of examinations of blood specimens have confirmed the reliability of this *résultante,* as Audain calls it. For example, assuming as normal figures, 4,900 polynuclear and 2,100 mononuclears (that is, in 7,000 leukocytes, 70 per cent. are polynuclears and 30 per cent. mononuclears), if the blood with 12,000 leukocytes shows 78 per cent. polynuclears to 22 per cent. mononuclears, then the polynuclear *résultante* would be $(780 \times 12) - 4{,}900 = 4{,}460$. The mononuclear *résultante* would be $(220 \times 12) - 2{,}100 = 540$. With infection in organs scant in lymphoid elements, the prognosis is good with a *résultante* of 3,000 to 8,000, and very good from 10,000 to 16,000 and above. With infection in an organ or tissue rich in lymphoid elements (as in enteritis, typhoid, paratyphoid and tonsillitis), the prognosis is favorable if the *résultante* is above zero. Below minus 600 it is grave, and very grave at minus 2,000 or below.

Audain insists further that the minimal temperature is what counts. The minimal temperature varies in inverse proportion to the *résultante* index. His studies of the behavior of the leukocytes in connection with the course of the infection have convinced him that treatment of infection should be focussed on means to increase the forces of the defensive leukocytes involved. Leukogenous medication should be our aim, and for this, sodium nucleinate, isotonic sugar solution, and turpentine are the main reliances.

- *Deficiency Disturbances in Soldiers. L. Bruntz and Spillmann.—p. 9.
- Film Treatment of Wounds. A. Combault.—p. 13.

Deficiency Disturbances from Army Ration.—Bruntz and Spillmann relate that they were impressed with the resemblance between the symptoms of trench foot and the symptoms presented by animals whose food does not contain vitamins. Their research has apparently confirmed that the cold and wet are merely secondary factors. The more they studied the experimental avitaminoses, the firmer became their conviction that many of the pathologic conditions noted in the soldiers at the front were the direct result of deficiencies in the diet. The neuritic disturbances of "trench foot" precede the trophic disturbances, accompany and follow them, and their distribution is the same as in pigeons on deficiency diets, and in beriberi. The neuritis with "trench foot" entails paresthesias, pains (as in the rabbit), motor disturbance (as in the pigeon), and circulatory disturbance with edema (as in the pigeon), with eschars. This insidious neuritis is thus enough alone to explain all the lesions of trench foot and the opportunity for secondary infection of all kinds, favored by cold and wet. They are inclined to ascribe to the deficient diet certain other disturbances, pains in the legs, asthenia, indigestion, certain psychoneuroses, insomnia, etc.

- *Organic Basis of Neurasthenia. Bernheim.—p. 19.
- *Transitory Lapse of the Will Power. P. Voivenel and R. Mallet. —p. 19.
- Digitalis Preparations. A. Remond and Minvielle.—p. 20.

Neurasthenia.—Bernheim remarks that he has been much disappointed to find that neurasthenia resists treatment by suggestion, which is so successful with simple irritable nervous weakness. In 50 per cent. of his cases of neurasthenia, he found the knee and foot reflexes exaggerated, and he accepts this as a sign of an actual organic lesion. Neurasthenia has been rarely encountered in soldiers; it does not have an emotive origin, but it may follow typhoid, influenza, or certain other infectious diseases. The neurasthenia may assume the form of neuropsychasthenia with a tendency to melancholia, or the gastro-intestinal form, or there may be mild spinal symptoms. In his experience, neurasthenia lasts at least six months, and it may return periodically for some months or years, or may flare up anew after an acute infectious disease. It seems plausible to assume that neurasthenia is the result of toxemia from some upset in the nutritional biochemistry or in the endocrine system.

Lapsing of the Will Power.—Voivenel and Mallet refer to instances in which soldiers who had been cited for special bravery deserted their post in the presence of the enemy. The psychopathic basis was easily determined, and the occurrence thus explained as a transient *fugue*, that is, a transitory frenzy, like epileptic automatism.

- *Formation of Precipitin after Injection of Serum. Nakata.—p. 64.
- Defensive Reactions in Epidemic Influenza. F. Wanner.—p. 71.
- Appendicitis of Influenzal Origin. Veyrassat.—p. 78.

The Floating Testicle.—Koenig reports a case in which the undescended left testicle repeatedly worked down into the inguinal canal and became incarcerated there under the skin, causing pain until it finally slipped back or could be pushed back into the abdomen. The incarcerated testicle finally became accompanied by symptoms of internal incarceration of the bowel, persisting after the testicle had spontaneously slipped back into the abdomen. The operation revealed a cord attached at both ends to the mesentery, an actual ligament, attached in the center to the testicle, and progressively obliterating the lumen of the small intestine. Koenig adds that after 30 the floating testicle may be regarded as certainly atrophied, and we need not hesitate to remove it or push it back into the abdomen and close the outlet.

Development of Precipitin After Injection of Serum.—Nakata reports research undertaken to decide how long it takes for precipitin to develop after injection of a heterogenous serum. He found that it takes from five to eleven days for the precipitin to form after a single injection of the antigen. It reaches its maximum between the ninth and fifteenth days, and persists till its final disappearance from the thirty-third to the seventieth day. The precipitin reaction is stronger and more lasting with beef serum, and least with goat serum. The amount of the antigen injected, above a minimum of 5 c.c., does not seem to influence the character of the precipitin reaction, but it is most intense by intravenous or intraperitoneal injection. In rabbits, the intravenous injection is the best. In guinea-pigs he was unable to obtain a precipitin reaction with a single injection of the antigen.

Revue Mens. de Gynécologie, d'Obst. et de Péd., Paris

March, 1919, **14**, No. 3

- *Melena in Newborn Infants. P. Balard.—p. 85.
- *Extramembranous Pregnancy. C. Gonnet.—p. 91.
- *Pituitary Preparations in Obstetrics and Gynecology. L. Pouliot.—p. 93. Conclusion.

Gastro-Intestinal Hemorrhage in the Newly Born.—Balard reports two cases in which, the second day after birth, there was melena, accompanied in one case by hematemesis. There was no excoriation of the mouth or of the breasts to which the hemorrhage could be traced, and the blood could not have been swallowed during the birth process as the blood was a fresh red. The tendency to hemorrhage kept up for twenty-four hours and then yielded to hypodermic injection of gelatinized serum (20 c.c.) plus 10 c.c. of serum from a horse that had been repeatedly bled. The blood of the newly born has not become accustomed to the new conditions of circulation, and mechanical factors readily explain the tendency to hemorrhage at this time. The arterial tension was rather low after the hemorrhage had begun, but it ran up above normal after arrest of the hemorrhages. This suggests that it may have been above normal to start with, but the hemorrhages had brought it down so low that infusion of these comparatively large amounts of fluids did no harm and only good.

Extramembranous Pregnancy.—The profuse watery, pinkish uterine discharge at the eighth month, with living fetus, was explained by finding that the fetus had escaped through a tear in the membranes and had developed outside of them. The fetus weighed 1,450 gm. and showed no signs of deformity, but died three hours after birth. Gonnet knows of only forty cases of extramembranous pregnancy on record. Breech presentation is the rule in these cases, and the placenta is usually of the marginata type.

Pituitary in Obstetrics and Gynecology.—This long review of recent literature on pituitary extracts is accompanied with ten pages of bibliographic references, but Pouliot remarks in conclusion, "The reader desirous to become completely posted on the subject will read with interest Mundell's article 'The Present Status of Pituitary Extract in Labor' in The Journal of the American Medical Association 68:1601, 1917. He will find there, besides a good bibliography, numerous statistics and critical analysis of certain unfavorable cases. Nothing in Mundell's work, however, conflicts with my conclusions or materially modifies them." Pouliot suggests that a pituitary extract might be added to the fluid for proctoclysis or to saline for infusion, with or without epinephrin. It might prove useful in this way in obstetrical or major gynecologic operations, to ward off or treat operative shock. It seems to act in such cases like epinephrin, only more mildly and the effect is more durable. He discusses the indications and technic in obstetric and gynecologic cases, especially its value in overcoming retention of urine in parturients and in starting up peristalsis, aside from its action on the genital organs.

and a corresponding rod of bone and periosteum is cut from the crest of the tibia, about 1 cm. thick. This bar is worked through the neck and head from the trochanter, after a passage has been dug for it, till the end emerges in the acetabulum. The porous condition of the bone renders this easy. It is important to have the periosteum project about 1 cm. beyond the end of the bar of bone. This end is turned down over the bone which prevents the periosteum from being stripped off from the bar as it is worked into place. He has thus operated in four cases, and the results of this slight operation to ensure remineralization of the joint bones have been very favorable.

*Transmission of Leishmaniosis to Animals. M. N. del Aguila.—p. 42.
*The Specific Agent of Yellow Fever. J. Arce.—p. 53.
Psychanalysis. H. F. Delgado.—p. 62.

Mycotic Dermatosis.—The man's arms, legs and chest showed thirty or forty pustules, the eruption having first appeared two years before, while at his country home, and proving rebellious to all measures. Several similar cases were known on the hacienda. A fungus was cultivated from the lesions, and the patient was sent to a spa for treatment with the waters. The fungus is shown in a colored plate; it is of the hyphomycetes type.

Urologic Aphorisms.—Velasquez dedicates his collection of 127 aphorisms to medical students in general. He says of oliguria that it is a sign of very grave prognosis in cases of intoxication, and warns that the tissues must be supplied with water at once to combat dehydratation, besides favoring elimination of the toxins. Frequent micturition in the obese warns of kidney disease. Frequent micturition, with or without polyuria, is a constant sign of chronic interstitial nephritis, especially in the beginning. Any discrepancy between the color of the urine and its density should suggest pathologic conditions. Every case of chronic disease that shows no improvement and in which no cause for the sickness can be discovered, may be classed as having a tuberculous, syphilitic or diabetic origin. Hyperchlorhydria calls for determination of the sodium chlorid content of the urine. Asthma with nocturnal polyuria suggests nephritis or diabetes; if the pulse is hard, nephritis may be assumed. Incontinence of urine ten or twelve days after childbirth suggests a vesicovaginal fistula. Most of the other aphorisms refer to the findings of different chemical tests.

The Kidneys in Influenza.—Arce reports eight cases of influenzal lobar pneumonia in which there was pronounced azotemia, but it proved transient and the patients recovered. Dalimier reported last year that massive albuminuria in influenza was observed almost exclusively in the fatal cases. Recovery with this finding was absolutely exceptional. In none of Arce's cases was the albuminuria of this massive type.

Transmission of Superficial Leishmaniosis to Animals.—Del Aguila reviews the research in this line by Splendore, Wenyon, Strong and others, and reports the first successful attempt in Peru to inoculate animals with American leishmaniosis, and the first anywhere of successful inoculation of rodents directly from man. His research has demonstrated further that the testicles are best adapted for the inoculation.

Etiology of Yellow Fever.—Arce reviews Noguchi's recent research on the specific agent of yellow fever. He says that before we can accept Noguchi's conclusions, the final proof must be obtained, namely, that pure cultures of the leptospira he has isolated will induce yellow fever in man, and also the determination of the cycle of evolution of the given leptospira in the mosquito until its final reimplantation in its vertebrate host. It would be an immense advantage if the leptospira or other germ should prove the actual specific agent, as this would enable us to detect the abortive and masked cases in adults and children which now perpetuate the scourge.

November, 1918, **9**, No. 11

*Treatment of Tetanus. E. S. Gomes.—p. 241.

Treatment of Tetanus.—Gomes relates that tetanus makes many victims in his part of Brazil. During ten years closing with 1915, there were 10,045 deaths from tetanus recorded throughout the state of S. Paulo. The annual coefficient from tetanus on the general mortality ranges annually from 9.9 to 19 per thousand. During the same decade there were 280 deaths ascribed to tetanus in the city of S. Paulo, 207 of which were in infants under 2. Rio de Janeiro also has a high tetanus death rate, 713 in a recent three year period, that is, about 9.5 per thousand of the total mortality. The proportion at Bahia has ranged from 15.8 to 28.3 per thousand of the total mortality. This high prevalence of tetanus is due in large measure to the fact that shoes are not worn, aside from the high incidence of tetanus from infection of the umbilical cord. In order to decide definitely what reliance can be placed on drugs in treatment of tetanus, Gomes treated large numbers of guinea-pigs with chloral, magnesium sulphate, sodium persulphate or phenol, after inoculation with tetanus. None displayed any efficacy, while antitetanus serum prevented the development of the disease even when injected subcutaneously several hours after the inoculation. Injected intraspinally its effect was most dependable. The intravenous route is preferable to the subcutaneous. In his clinical cases in recent years he has given from 5 to 10 c.c. of the antiserum by all three routes.

*Endemic Amebic Dysentery in Granada. A. Torres y López.—p. 79.
*Treatment of Habitual Constipation. M. Belaunde.—p. 85.

Endemic Dysentery in Granada.—Torres describes an epidemic of exacerbation of endemic dysentery in Granada. Fourteen cases in two months in a population of 4,000, in a remote valley in Granada, shows that amebic dysentery cannot be regarded in Spain as an exotic disease.

Hypodermic Treatment of Habitual Constipation.—Belaunde refers to F. F. Martinez' method of subcutaneous injections of sodium sulphate in treatment of constipation. The dose is 2 c.c. of a solution of 25 gm. sodium sulphate (by weight), in 100 c.c. of distilled and sterilized water (by volume). This amount is injected daily subcutaneously in the arm for ten or twelve days. When the stools become fluid, almost diarrheic, the treatment is suspended. The tendency to constipation seems to be permanently cured. In the innumerable cases thus treated, the constipation that had been rebellious for many years has not returned during the months and years since this course of treatment. If the course fails, he recommences with twice or three or four times the doses. But it has never failed in his experience when conscientiously applied, although some cases required thirty or forty injections. If the series is suspended, for any reason, it has to be commenced over again from the first. No saline or other purges must be allowed during the course of treatment or afterward. Belaunde writes to emphasize the *maravillosos resultados* obtained with this hypodermic treatment, and to reaffirm that, done according to Martinez' directions, a cure can be counted on in the overwhelming majority of cases. He summarizes eighty case histories to show the condition before and after the successful treatment. Spontaneous defecation occurred after the fourth injection of the sodium sulphate, and the stools became soft at the seventh, in most of the cases.

and a corresponding rod of bone and periosteum is cut from the crest of the tibia, about 1 cm. thick. This bar is worked through the neck and head from the trochanter, after a passage has been dug for it, till the end emerges in the acetabulum. The porous condition of the bone renders this easy. It is important to have the periosteum project about 1 cm. beyond the end of the bar of bone. This end is turned down over the bone which prevents the periosteum from being stripped off from the bar as it is worked into place. He has thus operated in four cases, and the results of this slight operation to ensure remineralization of the joint bones have been very favorable.

Hyperchlorhydria in Spain. R. M. Terol.—p. 193. Cont'n.
Graphic Record of Physical Signs of Pulmonary Tuberculosis. A. N. Blasco.—p. 195.

Nephritis.—In this closing instalment, Pascual discusses the general principles for treatment of nephritis, acute and chronic. He says that acute exacerbation of chronic nephritis may call for operative intervention on account of intense pain, hematuria, oliguria or anuria, or high fever and bad general condition. The latter would seem to contraindicate any operation, but Pousson, Israel, Legueu, Edebohls and others regard this as often imperative. Pascual warns that, whatever operation is attempted, all are grave with chronic disease of the kidney. The general anesthesia required is fraught with exceptional peril in cases of chronic nephritis. Another objection is that chronic nephritis is very frequently bilateral. Painful nephritis may require deep nephrotomy, incising the convex margin of the kidney down to the pelvis. Marsan compiled 82 cases in which this was done, with 66 complete cures and 8 with essential improvement, 3 not modified by the operation and 5 deaths. Pousson has reported 14 cured completely, 2 temporarily improved, no modification in one, and one death among 18 operative cases of nephritis dolorosa. Pascual remarks in conclusion that hematuric nephritis is the one form that benefits most by surgical measures. Hematuria of renal origin generally occurs only in unilateral chronic nephritis, of the type in which the lesions are limited to a few glomeruli. Nephrotomy has given sixteen complete cures in the 37 operative cases compiled by Pousson; the operative mortality was 8.3 per cent. Pascual regards nephrotomy as the preferable operation, generally speaking, when surgical measures are required for nephritis. Next comes decapsulation; nephrectomy only as a matter of necessity.

*Medical Abortion. A. L. Hermosa.—p. 193.
New Tendencies in Medicine. F. Paredes.—p. 196. Conc'n.
*To Facilitate Intravenous Injection. F. Robles.—p. 203.

Medical Abortion.—Hermosa explains that the progress of medical science in recent years has done away with almost the last necessity for professional infanticide. Cesarean section will overcome contracted pelvis, and we have measures to combat the autointoxication responsible for uncontrollable vomiting, albuminuria of pregnancy, grave jaundice and eclampsia, without sacrificing the life of the child. In conclusion he cites Vinay's statement that all the women delivered prematurely, on account of heart disease, at a certain large hospital died at the time or soon afterward.

To Facilitate Intravenous Injection.—Robles refers to the way in which the veins at the elbow sometimes refuse to swell when constriction is applied above, in readiness for the intravenous injection. To overcome this inhibiting reflex action he has the arm held hanging loose while he diverts the patient's attention.

*Treatment of Elephantiasis of the Leg. J. E. Ferrán.—p. 129.
Case of Prostatic Obstruction. D. Geiringer and J. Campuzano. —p. 136.

Elephantiasis of the Leg.—Ferrán comments on the frequency of elephantiasis in Cuba, and describes a method of treatment which is giving most satisfactory results. In a case illustrated "before and after," there is now no difference in size between the normal and the elephantiasic leg, when before the intervention this leg was enormous. He cuts out two ellipses, down to the muscle, several inches long, axial to the leg but not to each other. He then sutures the lips of the ellipse together, passing the catgut through the skin, then along the edge of the other tissues without traversing them, down to the muscle. After freshening the aponeurosis, the needle is passed horizontally in the depths of the muscle, then out on the other side in the same way. Four or five catgut threads are thus used to suture the lips of the ellipse together in a kind of "anastomotic inclusion," as he says. The lymphatics, veins and arteries form actual siphons by the intimate connection thus realized between the derma and the muscle. Other sutures are taken as usual, which serve for drainage, and a small wick is left at the lowest point of the incision. The operation is done under local anesthesia, *and the patient should sit with his leg down at the forty-eighth hour.* A compressing elastic bandage aids in the rapid reabsorption of the elephantiasic tissues. They disappear more completely than when masses are excised.

*Keratomalacia and its Treatment. R. Guiral.—p. 157.
Influenza at Batabanó. P. Pons y Zamora.—p. 160.

Keratomalacia and Its Treatment.—Guiral emphasizes that every ophthalmologist has to keep up with the progress in general medicine in order to practice intelligently. If he restricts his studies to the literature on his specialty, he will be neither an ophthalmologist nor anything (*ni oculista ni nada será*). This is especially evident in respect to keratomalacia. Until recently, he says, the family physician when he found he could do nothing in xerophthalmia, and that blindness was impending, ordered the child taken to an ophthalmologist, and the latter had to bear the stigma of the child's becoming blind, besides his sympathy with the family's grief over the misfortune. Recent research on vitamins has solved the mystery of keratomalacia, and shown how to ward it off and cure it. Cod liver oil and raw milk contain the vitamins the system is craving, but the families would shrink from giving either of them to a 2 months' babe with enteritis. In their ignorance of vitamins, they would consider such advice preposterous. Fortunately, however, lemon juice answers the same purpose, and this can be given to young infants. He orders strong lemonade, two lemons to a tumbler of sweetened water, and has the child given four table spoonfuls a day, by the mouth if possible, if not, by the rectum in four small enemas. By the end of eight or ten days not only the eyes return to normal, but the general condition shows marked improvement. He has thus treated twelve infants with keratomalacia, and except for a slight cloudiness in two of them, not seen until very late, all the eyes are completely normal.

been held in check: that is, typhus fever, cholera, recurrent fever, typhoid, scurvy and malaria, and, not least important, smallpox. Influenza with pneumonia, occurring in an epidemic sweeping over the eastern and western hemispheres, has been the epidemic that has baffled medical science and stands out with startling distinctness as the one uncontrolled epidemic. The death toll of pneumonia has almost equaled the battle casualties of those killed and dying of wounds in the American army. In spite of the failure to control influenza and pneumonia, this is an extraordinary record of disease control, and never, in any previous war, has the knowledge of medical science and sanitation, and the application of this knowledge been able to accomplish so much. We saw typhoid start as an epidemic in Belgium, in 1914, spread with its old-time fury among the troops at that point, and then we saw it conquered by sanitation and vaccination. We have seen typhus spread with terrible fury in Serbia and in Austria, we have seen typhus and recurrent fever break out in Russia, and again through the knowledge that these diseases are carried by body lice the epidemics were controlled. Cholera has started and been controlled through sanitation and vaccination, by both Russians and Italians. Tetanus has been practically eradicated among the wounded. Smallpox, appearing among the recruits coming from civil life, has been so quickly controlled that there were, from January, 1917, to April, 1919, in the American army of over 2,000,000 men, but six deaths from this disease. To appreciate fully the meaning of this result of preventive medicine and what the American medical profession has accomplished, let us study the battle casualties and disease rates of former wars, and, by this contrast, appreciate the achievement.

DESTRUCTIVE EFFECTS OF DISEASE IN FORMER WARS

Of course, any accurate and minute comparison requires carefully kept statistics, and such records are available only for the wars of the nineteenth century. Surgeons and physicians have been with the armies since antiquity, but they were as part of the retinue of some king, general or noble, and were not assigned to troops. Charles the Bold of Burgundy, in the last third of the fifteenth century, was the first one that definitely assigned surgeons to the troops as well as to the officers. This seems to be the isolated instance of a single ruler, for it was not till a hundred years later that the first surgeons were supplied to the British army, in an expedition to St. Quentin. In the middle of the sixteenth century the armies of Charles V did not possess surgeons or medical corps, for it is reported as an extraordinary occurrence that, in the siege of Metz, when Charles V, beaten by disease and famine, was forced to raise the siege of this town, his young opponent, the Duc de Guise, gathered the abandoned sick and wounded of the retreating imperial army and, contrary to the customs and traditions of the time, had them cared for by his own physician, the renowned Ambroise Paré.

However, it was not until the seventeenth century, in the time of Louis XIII of France, that surgeons were regularly appointed to the French armies, and not till 1660, when a standing army came into existence in England, were surgeons first regularly appointed to regiments in the English army. Not till the middle of the eighteenth century, however, was there a well-organized medical service in any of the armies. Field hospitals were not thought necessary until Cardinal Richelieu installed them, in 1639, in villages behind the fighting lines.

It is not usually realized that some of the greatest wars of modern times were fought with practically no provision made for the care of the sick and wounded, that the decision of wars has at times depended more on the wastage of the armies by disease than on the valor of the soldiers or the genius of the generals. The Emperor Frederick Barbarossa, in the Middle Ages, saw one army in Italy annihilated by sunstroke. Ten years later, after he had succeeded in storming and conquering the city of Rome itself, a pestilence swept away another army, and he was forced to flee, a fugitive, to Germany. In the Thirty Years War, the Swedish army under Torstenson fought its way from the Baltic Sea to the very gates of Vienna, where the bubonic plague so decimated his forces that he was compelled to withdraw and lose the campaign so brilliantly won. In the middle of the eighteenth century the bubonic plague again so raged, this time among the Austrian and Russian armies, that these nations were forced to bring the war to an unexpected ending and to make an unfavorable peace with Turkey. In more modern times, the disorganization and discouragement produced by disease in the French forces before Sebastopol was not a small element in hurrying the government of France to conclude peace before the ultimate aims of the campaign were accomplished.

For a background to modern hygiene, let us consider the occurrence of disease in the Thirty Years War, 1618-1648, a war fought between Protestant Swedes and northern Germans, aided, toward the end, by the French, against the imperial Catholic armies of Spain, Bavaria and Austria. This war had all the bitterness of other religious wars. The armies were often an unpaid rabble of mercenaries greedy for loot, who lived on the country, but who deliberately burned and destroyed all they could not use. They methodically wasted entire districts, thus adding famine to pestilence, for wherever these armies went they took with them and spread typhus fever. The numbers engaged, relative to modern times, were small, an entire army representing no more than one or two modern divisions, the strength of either side averaging from 20,000 to 30,000, occasionally more, often less. Bodart sums up the battle casualties of the thirty greatest engagements of this war as averaging 15 per cent. for the victors and 30 per cent. for the defeated antagonist. These losses were small indeed compared to loss by disease. The sick and wounded were uncared for except by their comrades or by the camp-followers; or they were left in villages or cities to be aided by the civilians, and were universally the foci of infection from which typhus fever spread far and wide. Smallpox was ever present in the communities. Dysentery and scurvy added their toll of death in the armies; typhus fever never ceased its virulent devastation, and, after 1632, bubonic plague imposed its terrors on the armies and stricken peoples alike. Great as was the destruction of life among the soldiers, whether from battle or by disease, the loss of life was always greater among the noncombatants, not only because of famine and pestilence, but also because of the brutal and barbaric conduct of the war. Prinzing records that the population of Wurttemberg lost by war, famine and pestilence, in five years, 300,000 persons, or three quarters of its inhabitants.

In the Electorate of Saxony, bubonic plague, typhus and dysentery, in two years, carried off 934,000 of the inhabitants. Three quarters of the entire population of Germany, over whose fields the war had chiefly been waged, were blotted out of existence, for the population dropped from 16,000,000 to 4,000,000, the logical consequences of barbarous warfare and no sanitation.

By the middle of the eighteenth century the armies of England and France had regularly organized medical corps. With its increased responsibilities the medical corps of England had been given an equivalent increased authority and independence, but the French medical service, from the eighteenth century even through the war of 1870, had neither independence nor authority, but was a subordinate part of the intendance, or quartermaster's department. In spite of the improved ideas of care of the sick and wounded in the armies of the eighteenth century, the mortality rate diminished but little. The hospitals were still only shelters for the very sick. Two, four, or even six patients were still crowded on a single bed. Overrun with vermin, with absolutely no ventilation, filthy beyond description, they still propagated typhus, plague and dysentery. Sir John Pringle, in discussing the causes of mortality in war, names hospitals as an important factor. And Turpin de Crisse declared that in the wars of the decade from 1731 to 1741 more men died in hospitals from lack of care than lost their lives in combat.

Typhus fever still raged as an epidemic among the armies in the Wars of the Spanish Succession, and in the Seven Years War of Frederick the Great. It was not till the nineteenth century, after the Napoleonic Wars, that the French hospitals showed any improvement. On the other hand, it was because of the experiences in the Napoleonic Wars that the English were able to improve the sanitary care of their wounded. This the historian Napier realizes, and he pays tribute to the success achieved:

> The extraordinary excellence of the medical officers may be said to have decided the day at Vittoria, for their exertions undoubtedly added a full division to the strength of Wellington's army, and without these 5,000 it is doubtful if his Lordship, with his unrivaled talent, could have carried the day.

Their efforts were directed more toward cure than prevention, although Jenner had, by the end of the eighteenth century, shown the first means of control, by preventive vaccination, of one of the decimating plagues, that of smallpox. In strange contrast to his habitual indifference to the fate of his sick and wounded, Napoleon seized on the discovery of Jenner, and by 1809 had succeeded in having his entire army vaccinated. There seems to be a general agreement that no man ever was more indifferent or cared less for the salvage of the sick and wounded of his armies than Napoleon. Duncan says that abandonment of the wounded was the rule by the French in the Napoleonic Wars. When not abandoned, they were huddled in buildings of every sort and left to die.

It is of more than passing interest that during Napoleon's war against Prussia, 1806–1807, typhoid seems to have been recognized. The French physicians at this period differentiated and accurately described its symptoms and lesions. From this time epidemics of typhoid are recognized and separated from the real typhus, which still ravaged both armies and population.

The retreat from Moscow and the Russian campaign of 1812 was probably the greatest military disaster of modern times. From recent authoritative French figures Bodart estimates that 680,000 crossed the frontier with Napoleon. Dysentery severely attacked the armies after they had crossed the Polish frontier, 80,000 men being down with it at one time. Of the 612,000 fighting strength, there returned to the frontier, according to Bodart, but 112,000 men. Lemazurier says that the great majority of the 30,000 French prisoners left at Vilna died. Faure claims that all of the French soldiers who fell into the hands of the Russians succumbed to typhus fever. It seems probable, therefore, that there were 100,000 men killed in battle, and at least 350,000 perished from starvation, cold and disease. Prinzing says that the instinct of self-preservation had kept the army together in a common line of march from Moscow to Vilna and on to Niemen. He adds:

> After crossing the river, however, at this point, the few unfortunate soldiers who had survived the awful misery of the march, hungry, with clothes in rags, with torn shoes, alive with vermin, with frozen and gangrenous limbs, scattered in all directions, some going home and others to strongholds that were in the hands of the French. Thus typhus fever, with which all parts of the army were infected, was spread in a comparatively short time over a large part of Germany.

The pursuing Russians did not escape free from the scourge, for in the three months from October to December they lost 62,000 soldiers, most of whom died from typhus. It is stated that the Russian armies in this campaign lost 200,000 killed and 150,000 wounded. The total of death by disease is not recorded.

The German campaign, a year later, was no less disastrous, and among the French and their allies there seems to have been some 60,000 killed and 196,000 wounded during 1813. Duncan thus describes the result of this campaign:

> But a few fragmentary battalions followed the eagles of Napoleon across the Rhine in November. The army lay scattered amid the villages on the route from Germany, the men dying by thousands and spreading a pestilence among the inhabitants. Reliable observers say that the retreat from Leipzig was no less ruinous than the retreat from Moscow, although there was no cold nor famine. The utter ruin of the army was the legitimate fruit of utter neglect of the sick and wounded.

Prinzing, studying the epidemic of typhus fever of 1813 and 1814, following the Russian campaign, believes that between 2,000,000 and 3,000,000 people contracted this disease, spread broadcast by the scattered armies of Napoleon, over 10 per cent. of whom died.

The Spanish War, in its six years' duration, 1808–1814, cost France over 90,000 killed. The deaths by disease are variously estimated as from 300,000 to 460,000 among the French army. We know that typhus fever was widespread and virulent. We know that yellow fever, in 1810 and 1811, raged furiously in the southern portion of Spain. It is known that in the siege of Saragossa, for example, of the 100,000 inhabitants, 54,000 died of typhus; and of the 30,000 soldiers, 18,000 died of the same disease before the city was forced to capitulate.

In striking contrast to this was the work of the English in the peninsular campaign during 1808-1811, under Sir James McGrigor. This surgeon had been in the Walcheren expedition on the coast of Holland pesthole of tropical diseases into a healthy and safe terrain, that the engineering genius of the United States Army might be free to construct the canal. The French under De Lesseps had failed because of the epidemic and tropical diseases which were at that time uncontrollable. Disease had defied and overcome engineering skill and genius. Preventive medicine controlled and conquered.

Ten years ago the practical application of the knowledge gained from the study of the epidemic of typhoid fever of the Spanish-American War brought about the compulsory inoculation against typhoid in the United States Army. It had been shown by the Vaughn and Shakespeare Board that nearly 65 per cent. of the typhoid fever of that war was transmitted by contact of man with man, and was not water borne. Hence sanitation could only reduce typhoid to a certain level and not eradicate it. The introduction of compulsory typhoid inoculation in the army has practically eradicated the disease. Following the work of the English medical corps in the Boer War, a United States Army surgeon, F. F. Russell, made possible the practical application of this method in the U. S. Army and proved conclusively that typhoid fever could be completely controlled. The American Army Medical Corps has, in the recent war, discovered the transmissibility of trench fever by body lice, and thus has shown the means of prevention of this new disease which, while killing no one, rendered thousands of men useless for weeks and ineffective for fighting. This discovery came to save thousands of men for the fighting lines at a time when they were urgently needed.

MODERN CONTROL OF DESTRUCTIVE DISEASES

Medical science has today, therefore, within its grasp the power to control the diseases which, in former times, decimated warring armies and spread out from these armies among the noncombatant populations. Formerly, when war broke out, it was almost inevitably followed by some dread pestilence among the civil populations of the countries in which the war was waged. By proper sanitation and preventive inoculation, dysentery and cholera can be abolished; by vaccination armies can be protected against smallpox. Body lice disseminate typhus, recurrent fever, and trench fever, and by proper disinfestation of these vermin these diseases cease to occur. Through sanitation and preventive inoculation, typhoid fever, the scourge of the two previous wars, is absolutely controlled, and this includes also paratyphoid, which has been recognized as a separate entity only since the Spanish-American War. In the Spanish-American War, 60.5 per cent. of all deaths were caused by typhoid, and in the present war 85 per cent. were caused by pneumonia. The typhoid of the Spanish-American War was due to local causes and local epidemics. The pneumonia of this war was beyond control, and was part of a world-wide epidemic that swept over both hemispheres, and the morbidity and mortality of some of the cities of this country exceeded those of the camps. Subtracting the death rate caused by pneumonia from the total death rate by disease in the recent war, we have 2.2 per thousand for the entire army on both sides of the water, which is practically a peace-time death rate. Meningitis has caused, in this war, ten times as many deaths as typhoid fever; pneumonia has caused two hundred times as many. Mumps and scarlet fever, of the infectious diseases of the young men, remain as yet to be controlled, but they are not of great import in the armies in war. The disabling type of disease coming under the head of venereal disease has, in this war, been so controlled that the number of cases brought from civil life was greater than the number occurring in the American Expeditionary Forces in France, which was reduced to twenty-two per thousand per year, a rate only one eighth as high as the incidence among recruits coming from civil life, and only one third as high as the best that ever had been accomplished in the army before.

Influenza, measles and pneumonia, in the respiratory group, still stand as baffling problems, and their control has not been accomplished. Measles appeared and spread until it no longer had material on which to spread, as one attack confers immunity to a second. Pneumonia, following influenza or originating as a primary disease, still eludes control. But the knowledge which we have gained in this war of the methods of its spread, of the various infectious organisms which produce it, and their various types and varying virulence, of its occurrence as a secondary complication to measles and influenza, has enormously increased. The value of the facts thus learned are incalculable, and belief is justified that the problem is better understood than ever before, and that we soon shall see the solution of these problems.

The occurrence in the camps of meningitis, another disease of the respiratory group, as far as its portal of infection is concerned, has been forty-five times as frequent in the army as its occurrence in civil life among the same age group. This has been due to overcrowding and the diminution of air space allowed the individual soldier in badly ventilated barracks. The responsibility for these sanitary sins rests on the General Staff and not on the Medical Corps.

VALUE OF LESSONS LEARNED IN DETERMINING ACTION IN FUTURE

What then are the lessons that we can draw for future action? There is no question but that the salvage of human beings, the protection of troops from disease in an army, renews and saves the fighting forces. Until recently, until medical science could control disease during war time, armies had been more decimated and injured by disease than through battle casualties. Now that, except for epidemic spread of respiratory diseases, the communicable and epidemic spreading diseases can practically be controlled, the medical corps of an army has become an essential part of the fighting organization. Whole nations must now go to war. No longer can they mobilize a selected portion of volunteers and send them to fight the war and defend the nation. Since all the youth of the nation must mobilize and turn to war, it becomes the duty of a general staff to save its man power and to salvage it to the greatest extent possible. The history of the Crimean War, of our Spanish-American War, and our experience in the recent war have clearly shown that only through proper representation on the general staff by those men trained in such salvage, and by experts in such knowledge of sanitation, can this duty be performed. When the General Staff of the United States Army comes to realize this fully, one cannot conceive that it will fail to give proper representation in its councils and organization to the Medical Department. The practical necessity for this was finally recognized in the A. E. F. by General Pershing and three medical officers were detailed at General Headquarters as substantive members of the General Staff. Responsibility and authority cannot be separated, and only by such organization can adequate authority equal the inevitable responsibilities.

In the mobilization of the industrial forces of the nation by the Council of National Defense, the health of the nation and the protection of both nation and its armies was regarded of such importance that it demanded direct representation of the medical profession on this board. This is also true of the navy, for its Medical Department is represented on the General Board. Oddly enough, the anachronism still exists that in the General Staff of the United States Army the Medical Department is regarded as an outsider. The safeguarding of the health and fighting vigor of an army, the salvage of its wounded, the saving of man power through protection from disease are still regarded as foreign to staff organization. The medical and sanitary formations are still regarded as noncombatants, although those serving with the troops often go forward and mingle with them in the combats, that the morale of the men may be better sustained. Duty demands it, and they have shown themselves willing, in this war, to be unarmed combatants, not noncombatants. The ratio of the medical officers killed and dying of wounds has been exceeded only by that of the infantry and artillery, which branches necessarily bear the brunt of the battles. The pro rata death rate of the medical officers has exceeded that of aviators and of engineers.

This subject is a matter for congressional action, but the profession of this country, while the experiences of this war are still vivid in its mind, must turn to the Congress, must make an intelligent exposition of these facts, and must bring about, by legal enactment, an adequate representation of the Medical Department on the General Staff of the army.

EDUCATIONAL NEEDS OF THE MEDICAL PROFESSION

One lesson of the war which stands out with great distinctness is the necessity for the American Medical Association to continue its unceasing struggle to raise the standards of medical education in this country. Such are the increasing demands made on the medical profession that the young men entering it today must realize that the broad and excellent education obtainable is none too good. It is not asking too much to require that all medical schools which are permitted to continue should soon be raised to the A Class.

There is another urgent educational need in this country that should be taken up immediately: that is, increase in the postgraduate opportunities for medical study. The opportunities that are presented in this country are practically undeveloped. It is for the profession to develop them, and every member of the Medical Corps of the army should be given an opportunity to avail himself, for a certain number of weeks each year, of the chance to study some branch of medicine or surgery at some medical center—not required to do it at his own expense, but detailed by the government to take up, for a definite number of weeks, his chosen branch of study. Physicians acquire their knowledge best by daily contact with opportunities which broaden their experiences. The opportunity to do this at short intervals, rather than at intervals of two, three or five years, would produce better results.

NEED OF IMPROVED ORGANIZATION

One very important duty to be performed soon is the reorganization of the Medical Reserve Corps and the rearrangement of the Medical Reserve officers and of the medical officers of the National Guard into one National Reserve Corps. This must be done when a realization that the medical profession in the regular Medical Corps and in the Reserve and National Guard Corps are all members of one and the same profession, united in desire to serve and obtain a single objective. Those in the Regular Corps have specialized in the study of medicine in its application to military requirements. The Reserve and Guard Corps have specialized in clinical medicine, with sufficient knowledge of military requirements to permit of their early adaptation to military environment when war comes. Equal ethical responsibilities rest on all alike, since all are called together for the common purpose of caring for the sick and wounded of the army; but the amount of practical responsibility must be unevenly distributed among individuals, that proper organization may be perfected.

Authority of the individual must always equal his responsibilities. Military authority is always expressed by rank and cannot be separated from it. Hence rank, authority, and amount of responsibility must coincide. The Reserve and Guard Corps should not be discriminated against in rank, as they have been in the past, because it invariably prevents authority from equaling responsibility, and thus cripples efficiency. One solution would be to have all Reserve Corps officers of equal rank, such as captain, and have the office held bestow the authority in proportion to the responsibilities contained therein. The administrator of each hospital unit must always have supreme local authority, but there should be an appointed group of clinical consultants in the different specialized branches of medicine, surgery and sanitation for the proper correlation of clinical procedures, that there may be uniformly good treatment and care given equally to all sick and wounded in all hospitals. Medical and surgical specialization was developed in the army for the first time in this war, and beyond question it must remain permanently. These consultants should be utilized as medical and surgical advisers on clinical subjects to the Chief Surgeon, with direct access to him without intervening mechanism of departmental heads. It is axiomatic that these consultants must have sufficient rank and authority to equal their responsibilities, and necessarily higher rank than the commanding officers of the hospitals under their supervision. These are but suggestions, and it is unnecessary to go further into details at this time, but some solution of this problem must be found soon.

RELATION OF RED CROSS TO ARMY

The relationship of the Red Cross and the army is not generally understood. The Red Cross is not a private society supported by private contributions, but is a governmental body incorporated by Congress, with a definite function, that of giving voluntary aid to the soldiers and sailors of the army and navy during war. It differs from other governmental functions in that it is not supported by congressional appropriations, but by voluntary contributions. Many of its functions and their limitation are defined in international treaties with other nations. Originally conceived to give aid to the sick and wounded in battle, and to place them and the attending medical and nursing personnel safely into a special noncombatant group, its functions have broadened and grown until they ramify, in war time, among civil and military populations alike.

When, two years ago, the war began with us, the popular idea in the army, among the majority of medical and line officers alike, of the full extent of Red Cross duties, seemed to be that the Red Cross workers were to be kept as far in the rear as possible, to hold the little hot hand of the homesick convalescent soldier, and, on off moments, make comfort bags for soldiers and sailors. The idea of the average person eager to go into Red Cross work was to make as many surgical dressings as possible and, with armfuls of these, keep as far forward in the advanced zone as possible, ready to rush on the field of battle and stem the hemorrhages of the wounded and gasping soldiers. Stern reality soon effected a compromise, and time only permits here of a short reference to some of the medical activities in their relation to the army.

The war has shown that the Red Cross has proved an excellent stop-gap for supplies, and a source of all kinds of emergency and surgical supplies and relief, even to complete and extensive hospitalization, when the situation called for them. No more satisfactory and cordial relationships could have existed between two departments than did exist in France between the Medical Department of the Red Cross and the Chief Surgeon's Office of the American Expeditionary Forces. Because of this relationship, the Red Cross was able to supply opportunities to the medical men in France which could not otherwise have been obtained. Through the broad-minded policy of Major Grayson M. P. Murphy, Red Cross Commissioner to Europe, there was formed a research committee, with American, English and French medical men, which fostered research and secured progress in medicine even during the war. The discoveries of the origin of trench fever and its transmission through body lice was the direct result of this. The standardization of blood transfusion, the striking progress of surgery of the chest, and the continuous study of surgical shock are other examples of work accomplished by this same committee. Through the Red Cross Research Society, whose membership consisted of all members of the Medical Corps in France, this research committee furnished a forum in which was discussed and given out the knowledge of medicine and surgery of the war, gathered in the years just previous to our entry. It proved to be the intellectual center for the medical portion of the American Expeditionary Forces, and here, discussion by the Medical Corps of the British and French armies in its meetings, gave to the members of the American Medical Corps the knowledge gained in the hard and cruel experiences of the three years previous to our entrance. It was by this means that the American Medical Corps started with the medical knowledge of 1917 instead of with the knowledge of 1915 or 1916. It thus trained and prepared thousands of officers by reenforcing their practical experience with knowledge of the experiences to come.

The Red Cross also published a medical journal, a digest of all war articles of the Allied countries, and disseminated these broadcast in the American Expeditionary Forces and among the medical corps of our Allies. It further disseminated knowledge by means of a library and a medical intelligence department that furnished, on request, any information regarding scientific subjects. It thus supplied medical knowledge, and prevented medical stagnation and deterioration through lack of knowledge.

One of the unforeseen but logical sequences of the Red Cross Research Society was to establish a liaison with the medical corps of our Allies. Instead of a slow and gradual acquaintance, there arose a rapid amalgamation and a rapid fusion into a frank and trusting friendship between the medical men of France, England and America. This proved to be one of the really valuable contributions which the Red Cross made to the war. Another contribution of great value was the making and furnishing to the army of the nitrous oxid for general anesthesia. Researches with this gas showed that, in the seriously wounded suffering from surgical shock, it did not increase this shock, as chloroform and ether did, nor did it tend to send into shock the seriously wounded. The death rate, with this general anesthetic, was 20 per cent. less among the collapsed and seriously wounded than with the other anesthetics. The Red Cross brought over to France a plant to manufacture this gas; it manufactured it and placed it up in the front hospitals of the advanced zone. The practical proof that such an anesthetic, in huge cylinders, could be carried forward to the advanced hospitals, and used in practical abundance back of the battle lines, was a successful accomplishment. The lives saved justified the expenditures, for its advantages were so definite that its use meant the purchasing of the lives of our wounded.

Another real contribution by the Red Cross, in administrative matters in the war, was the founding of the base hospital organizations on the advice of Gen. J. R. Kean. These organizations brought together from various hospitals groups of medical and surgical men and nurses who were accustomed to work together and who knew each other's ideas and ways of work, and had them fully equipped and prepared for service before war broke out. The Spanish-American War had shown how difficult it was to gather men quickly into efficient organizations with no previous acquaintance which accustomed them to work together. The base hospital units produced a homogeneous structure instead of a heterogeneous mass thrown together by haphazard, and even when members of the hospitals were taken out later and sent as leaders of other units and teams, there still remained the basic continuity, which proved of the greatest value. It is of the utmost importance for future preparedness that the Red Cross should have these base hospital groups ready to go at all times, and nothing should be allowed to stand in the way of this or of some similar plan. As is known, the Red Cross gave up these units to the army as soon as they were called to active duty.

It is a question, and one that should be fully discussed, whether or not it would be advisable for the Red Cross to retain control of the base hospitals in the rear zone of the army. This has been done in Italy, by the Italian Red Cross, with pronounced success, and the chain of hospitals continued up even into the advanced zone; but where they touched the advanced zone they left the control of the Red Cross and proceeded under the control of the army. The Red Cross can often obtain its supplies quicker than the army, and can often act independently in emergencies in which the army must proceed along more slowly acting established lines. The American Red Cross has shown conclusively in France that, with its own or with army personnel, it can furnish, equip, and efficiently run hospitals in the advanced zone, or in the rear as base hospitals. This has proved advantageous in an emergency. Would it not prove equally advantageous as an established policy?

NATIONAL CONTROL OF PREVENTABLE DISEASE

I desire to draw but one more deduction from the medical lessons of this great war, and that in reality is the climax toward which everything points. That is, if this nation, through its present medical knowledge, has within its grasp the power to control communicable, and hence preventable, diseases, there must be established a nation-wide controlling organization for this purpose, a National Department of Health. Over 33 per cent. of our young men were disqualified from the draft for physical defects. There is need of wider supervision of our growing boys and girls to build up a more robust nation, and it is especially urgent in rural districts. If we are to have some form of universal military service, the very necessity of its universality demands some general supervision of the health of the youth of the nation, through protection against the transmissible diseases, and direction over the giving of health to the people as we now give education. This war has taught that there remains economic value in the maimed and wounded, and it is our duty to develop this value to its fullest extent. The maiming and injury of our workers, in the everyday work of industry, far exceeds each year the battle casualties of this war, and there is an economic necessity and duty to be performed in the salvage and reconstruction of the industrially injured.

Malaria still prevents the use of large areas of our southern states, and saps the energy of a large portion of the population. Typhoid fever still rests as a blot on the rural hygiene of this country. The control of epidemics between states is already in the hands of the Public Health Service, and within states, if state authorities request aid. Quarantine from outside infection is also under federal control. There are many other federal activities partially supervising health and disease through the various departments of the federal government. But it all lacks the efficient power of central correlation, and there remain many public health activities that should be undertaken by central action, from some of the problems of infant mortality to the problems of the increase of degenerative diseases of late middle life. It is the duty of the American Medical Association, and of each member of each state association, to urge on Congress the establishment of a National Department of Health.

Hull (England) After-Care Colony for the Tuberculous.—This colony was opened in April, 1918. The first report detailing the history of the movement and work done to Dec. 31, 1918, has just been issued. The colony is intended for such persons as have previously suffered from tuberculosis, in whom the disease is arrested, and who are certified to be noninfectious and able to perform at least six hours of hard work daily. Every applicant undertakes to remain for at least one year, during which time the individual is brought to full earning capacity by a gradual process of training. The work consists of market gardening, fruit growing, intensive horticulture, sheep, poultry and pig raising. The women colonists also assist with light household duties. The rearing of medicinal herbs is also to be attempted during the coming year. The colonists pay a certain sum for their maintenance, but they receive pay for their work.

INTESTINAL PARASITES IN OVERSEAS AND HOME SERVICE TROOPS OF THE U. S. ARMY

WITH ESPECIAL REFERENCE TO CARRIERS OF AMEBIASIS *

CHARLES A. KOFOID, PH.D., SC.D.
(BERKELEY, CALIF.)
Major, Sanitary Corps, U. S. Army

SIDNEY I. KORNHAUSER, PH.D. (EVANSTON, ILL.)
Second Lieutenant, Sanitary Corps, U. S. Army

AND

J. T. PLATE, A.B. (ELIZABETH, N. J.)
Second Lieutenant, Sanitary Corps, U. S. Army

NEW YORK

The intermingling of men from the tropics and of troops which had seen service in regions where amebic dysentery is widely endemic with our own troops on the western front during the war has opened possibilities of increased infections by *Endamoeba dysenteriae* and other intestinal parasites. This is especially possible in cases of dust-borne, fly-borne or water-borne infections in which ova or cysts from the stools of infected men find their way into the food or water of troops in the trenches or in the even more exposed conditions attending a rapidly advancing army.

EXAMINATIONS FOR INTESTINAL PARASITES

Examinations of 1,200 men of the United States army who had been in overseas services, and of 300 men from home service troops, have made possible the following preliminary account of the relative degrees of infection in these two groups of men. This work has been carried on at the Army Laboratory, Port of Embarkation, New York, since Dec. 28, 1918. The overseas troops examined were sick and wounded soldiers in transit through Debarkation Hospital No. 3, New York City. They included men who had seen service in Flanders, Château Thierry, the Argonne and Toul regions, as well as quite a number from France who never reached the front. They are drawn from 584 different regiments, etc., and are therefore fairly representative of our overseas troops. They come from every state in the Union and constitute approximately a fair sample of our population. Only a small fraction of them saw service on the Mexican border. It is obviously impossible to determine what proportion of the infections detected in them were acquired overseas and which ones are of home origin.

The home service troops are mainly cooks, bakers and food handlers from the port of debarkation and principally from the Medical Department. Of the total of 300 men examined, eighty-two, or 27 per cent., bear foreign names suggestive of Russian, Polish, Italian or Spanish origin, and at least seven are negroes from Florida. This group, therefore, is less typical of the American troops as a whole than is the overseas group examined by us. They presumably present a higher degree of infection by reason of their origin than would a fair sample of our population.

---

* From the U. S. Army Laboratory, Port of Embarkation, New York City, E. H. Schorer, Major, M. C., U. S. Army, officer-in-charge.

* For an amplification of this subject we would refer the reader to an article giving further details of the work done at the New York Army Laboratory, namely: Kofoid, C. A.; Kornhauser, S. I., and Swezy, Olive: Criterions for Distinguishing the Endameba of Amebiasis from Other Organisms, Arch. Int. Med., to be published.

* In the names of the organisms mentioned in this article, I have followed the best biologic usage on the following points: (1) Dysenteriae in place of histolytica as the specific name for the ameba of human amebiasis. This usage will shortly be sanctioned by the Committee on Protozoology of the National Research Council, has recently been approved by the British Academy of Medicine, and is the current French usage. I shall use it in my report to the National Research Council. (2) Trichuris trichiura for Trichocephalus dispar. The latter is displaced by the former in all the best recent parasitologies, and is the legal name for the species. (3) Giardia for Lamblia, for the last-mentioned reasons.

Examinations for ova of intestinal worms were made by the brine-loop method,[1] while that for protozoan cysts was made by the direct smear method, with the use of Donaldson's iodin-eosin stain,[2] supplemented by the concentration method of Cropper and Rowe,[3] substantially as modified by Boeck.[4] Obscure infections have been critically determined by fixed smears stained in iron hematoxylin. The concentration method has added less than 10 per cent. to the infections detected by the direct smear, mainly *Endamoeba coli.*

Only a single examination was made except of thirty-six (3 per cent.) of the men examined from overseas and thirty-two (16.7 per cent.) of the home service troops. In these, two or more samples were secured for examination. In the overseas group, the reexamination of thirty-six patients, with a total of ninety-nine examinations, or 2.75 examinations per individual, increased the number of different infections detected from forty-four to seventy-nine, or from 1.2 to 2.2 per individual. Thus the first examination revealed 56 per cent. of the infections found in 2.75 examinations. In the home service men, the examination of nineteen patients, with a total of sixty-six examinations, or 3.5 examinations per individual, increased the number of infections detected in these cases from thirty-two to fifty-nine, or from 1.7 to 3.1 different infections per individual. In this group the first examination revealed 54 per cent. of the infections found in 3.5 examinations per individual.

This limited finding points in the same direction as the fuller data of Dobell[5] and others in England, where approximately one third of the protozoan infections detected have been found on the first examination. In view of the large percentage of cases in which we have been able to make only one examination, it is highly probable that the total percentage of men infected among those we have examined is considerably higher than our records indicate for the protozoan infections including that of amebic dysentery. If Dobell's[5] ratio is accepted as applicable to our findings, our records of infections by protozoa may be increased approximately threefold if one is to estimate the total extent of the infections really present. The accompanying table presents a summary by numbers and percentage of infections of 1,200 troops from overseas and 300 who have had only home service.

TABULAR SUMMARY OF INFECTIONS BY INTESTINAL PARASITES IN 1,200 OVERSEAS AND 300 HOME SERVICE TROOPS OF THE UNITED STATES ARMY

EXTENT OF INFECTION WITH INTESTINAL PARASITES

An inspection of the table shows that the infected men (798, or 66.5 per cent.) are relatively more numerous in the overseas group than among these who have had only home service (177, or 59.2 per cent.), and on computation it appears that overseas men average 1.32 infections by different parasites per man as contrasted with 1.23 infections for those having home service only. This indicates that many of the infections were presumably carried overseas and not acquired there in the first instance, although there is some evidence that many overseas men carry heavier infections than do home service troops. In determining the significance of this slight difference, the sources of the home service men previously referred to should be considered. It may be that the percentages of infections found among them are somewhat higher than they would be in the more representative troops overseas.

The detailed analysis of the data exhibits certain very significant features. In the first place, the men with hookworm infection were all, with two exceptions, one from Italy and one from Massachusetts, from the known area of hookworm occurrence in this country. There is thus no definite indication of acquisition of this infection overseas. The situation is strikingly different with regard to infections by *Trichuris trichiura,* the whipworm. In home service troops there were six infections, or 2 per cent., while in the overseas troops there were seventy-two, or 6 per cent. This threefold increase is all the more significant when allowance is made for the fact that five of these infections were in recent immigrants from Italy (four) and Russia (one). If we deduct these numbers, the percentage of infection in the remaining falls from 2 to 0.3 per cent. Even this percentage is probably not representative of our troops on departure overseas. An examination of 145,016 men in the Southern Department, made by the laboratory car *Metchnikoff,* detected only 162 cases of infections by *Trichuris,* or 0.1 per cent. These men were mainly from Texas and

Oklahoma, but representatives of every state in the Union were included.

Infections by *Trichuris* in 1,200 overseas men were seventy-two, or 6 per cent. This is three times that in the home service group, or eighteen times if known immigrants are excluded, and sixty times that in the large body of representative troops from the Southwest. The greater part of these infections thus appeared to have been acquired overseas. Brumpt[6] observed from 30 to 70 per cent. infections in necropsies and stool examinations at Paris, from 72 to 82 per cent. in the miners of Lorraine and Verdun, and 100 per cent. in central Italy. Infections by Trichuris appear to be quite common in Europe.

The ova of *Trichuris* are discharged in the stools of infected persons; there is no intermediate host, and infections occur, so far as is known, only by mouth, when food or water is contaminated with infected feces. The ova are highly resistant to adverse conditions, and, under control, have been kept alive for five years in the infective stage. Sanitary conditions in rural France, and in the zone of advance on the western front, provide favorable opportunities for contamination of food and water by these resistant ova. The agency of flies in spreading this and other intestinal infections is well known, and the plague of flies at times on the western front during the military activities of the summer of 1918 is a matter of abundant testimony by those engaged therein. This increase in infection by *Trichuris* in overseas troops, as compared with that in home service troops, is an index of some value of the extent and degree of the exposure overseas to fecal contamination of food and water.

The most marked contrast, however, between infections in home service and of overseas troops is seen in the case of infections by *E. dysenteriae*. In the former there are nine infections, or 3 per cent., while in the latter there are 130, or 10.8 per cent., an increase of nearly threefold in the overseas troops over the infections in the home service troops examined by us.

In estimating the significance and value of these results regarding carriers of amebic dysentery, the following circumstances should be considered:

1. In all cases of infection by *Endamoeba nana*, a small tetragenous intestinal ameba of man recently described by Wenyon and O'Connor[7] as *E. nana*, we have differentiated this parasite from *E. dysenteriae* in our findings. It is, as the table shows, a very common ameba in man in both overseas (27.1 per cent.) and home service (30.7 per cent.) troops. There is some evidence in figures in the voluminous earlier literature that this ameba has in some instances been confused with the true dysenteric ameba. The possibility of such confusion renders previous reports of carriers of *E. dysenteriae* in this country and elsewhere tentative and subject to revision. This applies to determinations on both cysts and free amebae, for the former are tetragenous and the latter have ectoplasmic pseudopodia as has *E. dysenteriae*.

2. There has been little, if any, selection of cases for examination. The data represent the average run of the sick and wounded men received at Debarkation Hospital No. 3. They are not, as a rule, dysenteric patients, though many of those carrying cysts of *E. dysenteriae* report one or more attacks of diarrhea or dysentery, in some cases with the sick call and treatment, while on the western front. There are some instances of infection by *E. dysenteriae* with no previous record of intestinal disorder. This is often the case in the infections among home service troops.

3. In only a small percentage of cases has more than one examination been made. Continued examination for six successive days, as recommended by Dobell,[8] would unquestionably increase the number of infections detected. Results in Great Britain indicate that approximately one third of the cases detected on six successive examinations may be detected by experienced examiners on the first examination.

NUMBER OF PARASITES DISCHARGED BY CARRIERS

The presence of these carriers of amebic dysentery constitutes a menace to health in the communities in which they reside, especially where sanitation is neglected and the fly nuisance prevails. The number of cysts discharged daily by a carrier of amebic dysentery varies greatly according to the degree of infection. A patient moderately infected with *E. dysenteriae* was kept under daily examination for forty-two days, and the whole stool was stirred to a uniform suspension and diluted to from 500 to 1,000 c.c. with physiologic sodium chlorid solution. The numbers of cysts of *Giardia intestinalis*, *E. dysenteriae* and *E. coli* were determined in the counting chamber of a hemacytometer and computed for the stool as a whole, with the result that the *E. dysenteriae* cysts were found on twenty-six of the forty-two days in numbers ranging from 330,000 to 45,000,000 per day, averaging 14,520,000 for the twenty-six days, or 8,145,000 for the whole period of forty-two days. Cysts of *Giardia intestinalis* were present on only seventeen of the forty-two days, in numbers varying from 5,000,000 to 3,625,000,000 per stool, and averaging 965,200,000 per day. *E. coli* was much rarer, being found in this case on only three of the forty-two days, with an average of 3,110,000 cysts per day for the three days. The margin of error in these computations is large, but, after due allowance is made for this, the number of cysts discharged from carriers is still large enough to provide for extensive dispersal by flies or other agents. The size of these cysts ranges from 5 to 20 microns in the main, most of them being from 7 to 15 microns in diameter, and they are thus of such volume that they could easily be carried on the feet of the fly. Computations show that from 100 to 150 of the larger cysts, and from 500 to 2,000 of the smaller ones, could be crowded in the area of a fly's foot in a single layer. The agency of flies in such distribution has been suggested by Craig,[9] and experimentally proved by Wenyon.

THE CARRIER PROBLEM

The possibility that the carrier problem in the case of amebic dysentery and other human protozoan infections is a much larger one than hitherto generally recognized is raised by the data here presented. Furthermore, the findings among home service troops are indicative that the endemic area of infection by *E. dysenteriae* in the United States is not confined to the Southern states. This is confirmative of the findings of Smithies[10] and of the earlier findings of Craig.[11]

The presence of distinct size races in *Endamoeba dysenteriae* has been determined by Dobell.[12] Our material shows evidences of similar diversification, but as yet without evidence of the correlation of any particular races with cases in which clinical symptoms of disease have not as yet appeared. Extensive experimental evidence is needed to test the pathogenicity of these various races.

THE LOCAL USE OF ANTIANTHRAX SERUM IN TREATMENT OF ANTHRAX *

JOSEPH C. REGAN, M.D.
BROOKLYN

Various methods of local treatment have been tried in the therapy of anthrax. Among the measures used to destroy the pustule are, (1) excision, (2) the application of chemical or thermal cautery, and (3) the injection of germicides into the region of the pustule—such as tincture of iodin, phenol (carbolic acid), and a solution of mercuric chlorid. All these methods of treatment are objectionable, in that they either cause more or less extensive scar formation, the contraction of which often leads to disfigurement of the part, or are apt to produce toxic or poisonous symptoms, according to the substance injected. Excision has also the additional danger of laying open the blood and lymphatic channels so that symptoms of systemic infection may supervene, and the operation by no means always terminates the local process. Moreover, most of the methods, by their destructive action on the tissues, tend to increase sloughing, retard healing, and subsequently greatly prolong convalescence.

Hence, some method of treatment which does not possess these objectionable features would be desirable providing it proved effective in controlling the infection. Antianthrax serum has been used for some years in the treatment of anthrax, especially in France and Italy. Several authorities have reported a decided lowering in the mortality rate as a result. Thus Sclavo[1] reports a striking fall in the mortality in Italy, from 24 per cent. to 6 per cent., following the use of serum. Encouraging results are also reported from France and England. The serum has been used but little in this country as compared with Europe. The action of the antiserum is little understood, but it has been shown experimentally to possess prophylactic and therapeutic properties in animals (Marchoux[2]). It has always been administered by either subcutaneous, intramuscular or intravenous injection. I could find no record in the literature of its previous use locally.

The following report is therefore made in order to call attention to the satisfactory results of the injection of serum locally around the lesion. Another case of similar character has previously been reported.[3] The modus operandi of the serum is rather difficult to explain at the present time, as so little is known of the type of antibodies which it contains. However, clinically the method was followed by unusually rapid improvement and by recovery of the two patients treated. It possesses none of the disadvantages of the previous methods of local treatment, and for this reason should be preferable providing that future reports continue to establish its value. It is of considerable importance that a recently prepared serum be used, one that is not more than six months old. It must be remembered, of course, that no local treatment can be effective if a blood infection exists, and for this reason additional serum should always be given, either by intramuscular or intravenous injection depending on the severity of the case. However, there can be little doubt that proper local measures, if used early in the disease, will reduce to a minimum the chances of an anthrax septicemia.

REPORT OF CASE

A man, aged 19 years, was admitted to the Kingston Avenue Hospital, Dec. 30, 1918, with a diagnosis of anthrax.

History.—His family and previous history were irrelevant to his illness. He was not addicted to any kind of alcoholic beverage, nor did he smoke, and there was no history of venereal disease. For the previous eight months the patient had been working in a factory in which hair brushes of various kinds were manufactured. His work had been mostly sweeping up the floor, handling hair, etc. On Friday, Dec. 27, the patient noticed a small red pimple on his cheek. It was not very painful and gave him no particular trouble. On the following day he began to feel more discomfort; the cheek began to swell considerably and he could not lie on that side owing to the pain in his neck. He visited a private physician, who advised him to go to the hospital for treatment.

Physical Examination.—On entrance, the patient was rather ill and somewhat irrational. He answered questions poorly, and could remember little of the manner of onset of his illness. On the left cheek there was a considerable swelling. The center of the swollen area was occupied by a pustule, which was elevated above the surrounding tissue and measured almost 3 cm. in diameter. The inner part of the pustule was comprised of a black depressed eschar, which was of a rather leathery and gummy consistency, and was so adherent to the surrounding tissue that it could not be removed. Around this central eschar there was a white elevated border, the "blanched zone," and this, in turn, was encircled by a red areola. At the outer margin of the eschar there were a number of small elevations resembling vesicles, which discharged continuously a serous secretion, giving the entire pustule a peculiar, moist appearance. The tissues immediately around the pustule were very edematous and infiltrated, the swelling extending downward to the angle of the jaw and inward to the left eye, causing such marked edema of both lids that the eye could not be opened. The edematous area was not particularly sensitive; it did not pit on pressure and was not of a hard consistency.

General examination of chest and abdomen failed to show any very definite pathologic condition with the one exception that the heart sounds at the apex were of rather poor quality. The reflexes were normal in response. The temperature, on admission, was 100, pulse 92 and respirations 24.

Clinical Course.—Smears and cultures were taken on admission from the secretion of the vesicles and from the base of the pustule, by lifting up as far as possible the margin of the eschar. A blood culture was also taken. On the following day, December 31, the smears and cultures having proved positive for anthrax, a needle was inserted into the skin at the margin of the red areola, being directed fairly deeply into the subcutaneous tissues at the base of the pustule; it was then connected with a syringe and 12 c.c. of antianthrax serum was injected very slowly into these tissues in such a way as to almost circumscribe the pustule, the needle being of necessity inserted at three different points around the lesion. Thirty c.c. of antianthrax serum were also injected intramuscularly into the buttocks. That night the temperature rose to 102 and the pulse to 110, evidently owing to a serum reaction.

[3] Regan, J. C., and Regan, C.: Am. J. M. Sc. **157**: 782 (June) 1919.

Jan. 1, 1919, the patient was somewhat improved. There was a slight extension of the edema in the tissue surrounding the pustule, and there was a rather profuse discharge of serous fluid from the vesicles, but the patient was brighter and decidedly rational. The local injection of 10 c.c. of antianthrax serum and 30 c.c. intramuscularly was repeated.

The morning of January 2, the temperature had fallen to normal and the patient was greatly improved. He was sitting up and stated that he felt very much better. The pustule was drying up, both the red inflammatory areola and the white zone having disappeared. The centered eschar appeared depressed, the vesicles had almost dried up and the surrounding edema was greatly reduced in degree and in extent, the patient being able to open his eye. The lymphatic glands at the angle of the jaw were definitely enlarged. As the lesion had so much improved, no further injection of serum was given, the lesion being merely covered by a wet dressing of antianthrax serum.

January 3, the improvement was progressive and marked. The central eschar was beginning to loosen up at the margins, where it could be lifted off from the underlying tissues, but was intimately attached at the center of the lesion. The surface beneath presented the appearance of healthy granulations. The pustule was rapidly drying up, and the surrounding edema had practically disappeared. The cervical glands at the angle of the jaw had swollen to the size of a small marble. An injection of 10 c.c. of serum was made into the region of these enlarged glands. Cultures were again taken from the lesion.

January 4, the patient's condition was very good. He was then up and around. The pustule was reduced almost to half its original size, consisting only of the small, black eschar. The swelling of the glands had greatly diminished. The temperature continued normal.

January 17, the wound was almost healed. There was a small, dark, thin crust over its central portion. The crust was intimately attached by an elastic and fibrous pedicle to the subcutaneous tissues beneath, and had the appearance of a piece of burnt leather. The glands at the angle of the jaw were still slightly enlarged.

January 19, the crust was removed. The base of the pustule was touched up with tincture of iodin, and the patient was discharged, evidently entirely recovered.

February 25, the patient was seen again. He was in very good health, and there was no evidence of any detrimental effect due to the recent attack. At the site of the pustule there remained only a small, circular scar, somewhat depressed below the surrounding skin.

Pathologic and Bacteriologic Findings.—Blood counts revealed: December 31: total leukocytes, 16,400; polymorphonuclears, 76 per cent.; lymphocytes, 22 per cent.; transitionals, 2 per cent. January 1: total leukocytes, 15,000; polymorphonuclears, 78 per cent.; lymphocytes, 19 per cent.; mononuclears, 2 per cent.; eosinophils, 1 per cent. Blood cultures were taken December 30 and 31, and both remained sterile. Smears made from the pustule, December 30, revealed pus cells and a rather large number of bacilli, gram-positive, long, square at the end and rough in outline. Cultures on agar plate in twenty-four hours showed two types of colonies, several being rather large, from 4 to 5 mm. in diameter, dry and opaque, and of whitish color with scalloped borders; and the others more numerous, smaller, from 1 to 2 mm. in diameter and grayish color. On microscopical examination the smaller colonies showed staphylococci. The larger colonies were found to be composed of gram-positive bacilli, single and in chains, very similar to those found in the direct smears. Hanging drop showed the bacillus to be nonmotile.

The large colonies, evidently anthrax, were transplanted to plain agar for further study and for animal inoculation. These transplants were examined two days later and revealed the same dry, opaque colonies with fringing projections so common in anthrax. On low magnification the colonies resembled a head of hair. The same gram-positive bacillus, previously noted, was found on smear, this time in pure culture. After several days later smears showed spores of an elliptical shape, one in each bacillus.

Animal Inoculation.—An emulsion was made in broth of the pure growth obtained. Then 10 drops of this emulsion were injected into a mouse at the root of the tail. The animal died suddenly twenty-one hours later, having been apparently in fair condition in the interval.

Smears from the site of inoculation and the internal organs showed the same large gram-positive bacillus. Likewise cultures presented typical colony characteristics and showed the anthrax bacillus on smear.

January 3, a culture was again taken from the lesion. It showed no anthrax bacilli. Only staphylococci were found. On the 9th the same procedure was repeated with the same result.

CONCLUSIONS

1. The local measures now used in the therapy of anthrax, such as excision, cauterization, injection of germicidal solutions into the immediate region of the pustule, are all objectionable either in that they cause extensive scar formation with subsequent disfigurement, or are apt to produce toxic or poisonous symptoms.

2. The injection of antianthrax serum[4] into the tissues surrounding the pustule, while possessing none of the disadvantages of the previous methods of local treatment, has a very rapid and complete effect on the pustule, not only in arresting its further development, but also in producing a subsidence of all local inflammatory symptoms.

3. The injection is made with an antitoxin needle and syringe, the needle being inserted just outside the margin of the lesion and directed toward the subcutaneous tissues at the base of the eschar. The needle may have to be introduced at three points in order to encircle the pustule. The serum is introduced very slowly, the dosage varying from 10 to 15 c.c. It was administered once daily till the local process was controlled, usually two or three injections being sufficient.

4. Local measures must also be accompanied by suitable general treatment; hence serum should also be given either intramuscularly or intravenously.

5. Local treatment in order to effect a cure must anticipate the onset of an anthrax septicemia.

---

[4] The antiserum used was furnished on request by the chief of the Bureau of Animal Industry, Department of Agriculture, Washington, D. C. I wish to express my thanks for the cooperation of this bureau and its promptness in sending the antiserum.

Against Unethical Advertising.—The *Gazetta degli Ospedali* relates that the Ordine dei Medici of Palermo, Italy, recently passed resolutions to the effect that the notices published by physicians in the daily papers must be of uniform style and bear the heading "Notice Approved by the Ordine dei Medici. Also that a placard denouncing blatant advertising—the placard to be supplied by the organization—should be displayed in physicians' offices, sanatoriums, etc., and also in drug stores, railroad stations and cars and in hotels. A special permanent committee was also appointed, to comprise eleven members, whose task is to watch over the enforcement of these regulations and of others that may be adopted, aiming to secure the cooperation of the municipal authorities to combat abuses, and possibly secure the revocation of the license to practice in case of flagrant offenses. The funds for the purposes outlined are to be collected from those specially interested. The committee will seek by circulars, etc., to educate the public to the moral and material importance of this campaign against "indecorous advertising."

SOME CLINICAL OBSERVATIONS ON THE INFLUENZA EPIDEMIC AT CAMP UPTON

FROM SEPT. 13 TO DEC. 1, 1918

IRVING P. LYON, A.B., M.D. (Buffalo)
Major, M. C., U. S. Army; Chief of Medical Service, Base Hospital
CHARLES F. TENNEY, M.D. (Toledo, Ohio)
Captain, M. C., U. S. Army; Assistant Chief of Medical Service, Base Hospital
AND
LEOPOLD SZERLIP, M.D. (New York)
First Lieutenant, M. C., U. S. Army; Assistant in the Medical Service, Base Hospital
CAMP UPTON, YAPHANK, L. I., N. Y.

It is not our purpose, in offering this brief contribution, to analyze the epidemic as seen at Camp Upton in its many complex relations, epidemiologic, etiologic, bacteriologic, pathologic and clinical. It would be duplication and reduplication to add another such report to the many admirable ones that have already appeared in the journals. The disease at Camp Upton resembled closely the disease in other camps, being part of a general pandemic, sweeping widely and rapidly, and varying only in detail in camps similarly constituted. The bacteriology and etiology of the disease were carefully studied at Camp Upton, but the study yielded no conclusions of value. But we desire to present the basic clinical statistics for record, to make a few comments thereon, and in particular to describe in more detail than we have seen described the criteria and methods of diagnosis of the secondary bronchopneumonia following influenza.

ORIGIN AND NATURE OF EPIDEMIC

The epidemic of influenza was imported into Camp Upton, N. Y., directly from Camp Devens, Mass., by the transfer of troops bound overseas. It began abruptly on Sept. 13, 1918, with the admission to the base hospital of thirty-eight cases. Thereafter it increased rapidly, reached its apex, October 4, with the admission of 483 cases, then declined abruptly until October 22, when only eleven new cases were admitted. The primary epidemic covered a period of forty days (from September 13 to October 22, inclusive), with the admission to hospital of 6,131 cases.

Following the primary epidemic, cases of true influenza continued to appear irregularly for a considerable period, but in moderate number only. We regarded cases occurring between October 23 and the end of November as constituting the late or secondary epidemic. There was a total of 816 admissions in this period, contributed chiefly by new arrivals in camp or by groups of individuals from organizations previously protected by successful quarantine.

After November, cases of undoubted influenza became more and more rare, but cases of infectious tonsillitis and sore throat more frequent. So frequent, indeed, were such cases that they constituted a mild epidemic which has continued to the present time (April 1, 1919). The differentiation of these cases from true influenza was often difficult or even impossible, individually. But when taken as a group or as a whole it seemed clear that they were not simple influenza but a peculiar form of infectious tonsillitis or sore throat.

Their general features resembled closely those of influenza—marked infectiousness, abrupt onset, chilliness, high temperature, headache and backache, flushed face, injected and glassy conjunctivae, cough and throat symptoms. The throat showed congestion, redness, sometimes slight edema of the uvula, and in the majority of cases special involvement of the tonsils. These were usually congested, swollen in varying degree, and in particular smeared over with one or more patches of a very thin, delicate membrane which was readily removed by swab. Occasionally the membrane was extensive, thick, dense and adherent. Diphtheria and Vincent's disease could be excluded by bacteriologic examination. Infrequently, a true follicular tonsillitis was exhibited. Rarely, peritonsillar abscess developed. In many instances on casual and first examination the tonsils did not appear to be specially affected beyond sharing the congestion of the throat in general. But repeated and exact examination with strong light usually convinced one that the tonsils were specially involved and most frequently exhibited some grade, if only slight, of the membranous deposit above described. Many doubtful and atypical cases were observed. Bronchopneumonia and empyema were the chief complications but occurred far less frequently than with true influenza. No organism was found that could be surely incriminated as the cause of this throat infection. The *Streptococcus hemolyticus* was recovered in a considerable proportion of the cases but was not constant.

We have evidence of the prevalence of a similar throat affection at such widely separated points as Boston and Buffalo and many other places, and we would direct attention to this affection in relation to late statistics of the epidemic of influenza, as tending to vitiate their value. In consequence we have drawn a line at November 30 in terminating the period of the secondary epidemic of influenza at Camp Upton, regarding all diagnoses of influenza thereafter as unreliable and generally confused with the throat affection prevailing. Indeed, it would be safer to terminate the epidemic of influenza earlier for the purpose of statistical study.

The clinical characteristics of the influenza and its complications as seen at Camp Upton were the counterpart of the disease as seen at Camps Dix, Mills, Merritt and other camps in the northeastern section of the United States, as acknowledged by representatives from these camps who visited our wards during the height of the epidemic. Probably the disease was more or less similar everywhere, but varied in special features and intensity in different places, as would be expected. The disease at Camp Upton was equal in intensity and virulence to that at the other neighboring camps mentioned. The impression received in going through our pneumonia wards (holding at one time about 900 patients) was one of horror at the frightfulness of the sight of the hopelessly sick and dying and at the magnitude of the catastrophe that had stricken wholesale the young soldiers prepared to face another enemy but helpless before this insidious one. The memory of this sight will haunt for life the minds of those who saw it.

STATISTICAL TABLES AND CHARTS

The accompanying tables and graphic charts based on these tables give the main statistical data of the epidemic of influenza at Camp Upton. The figures are all from official sources. The figures for influenza are for patients actually admitted to hospital. In addition there were numerous cases of influenza of milder type in which the patients were not admitted to hospital and were not enumerated and in consequence are not included in these statistics. Their number is unknown but believed to be large. The figures for pneumonia are as accurate as diagnostic criteria permitted, and special precautions were taken to secure the complete reporting and enumerating of all cases of pneumonia. The figures for deaths are absolutely accurate. A special statistical office was maintained by the medical service from the beginning of the epidemic to keep full and accurate records, and in consequence we believe that our figures from the base hospital are exceptionally complete and reliable.

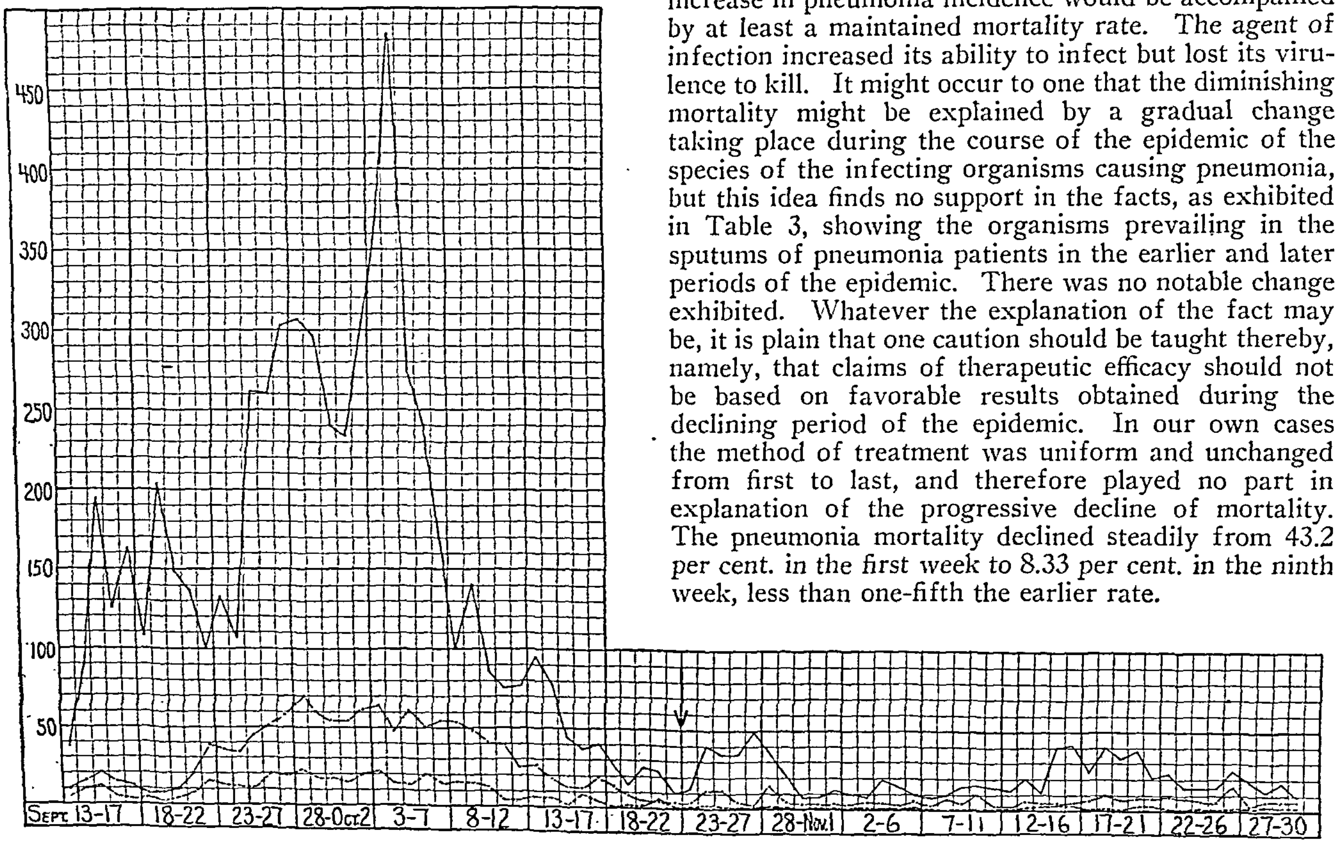

Chart 1 (illustrating Table 1).—Number of admissions for influenza by day, number of each day's cases of influenza in which pneumonia later developed, and number of each day's cases of influenza in which the patients ultimately died (up to Jan. 1, 1919): solid line, influenza; line of dots and dashes, pneumonia; broken line, deaths; the arrow indicates end of primary epidemic.

In compiling the tables, giving figures day by day, we have arranged the columns so as to show, by reading laterally, later complications (pneumonia, empyema) and ultimate deaths for each separate day's admissions of influenza patients, followed up to Jan. 1, 1919. This arrangement permits an accurate comparison of the later course and the end-results of each separate day's group of cases of influenza throughout the epidemic and followed over a period of almost two and a half months subsequent to the termination of the primary epidemic. So far as we have observed, this method of statistical report has not been employed heretofore in the published reports on the epidemic from other military camps. Prolonging the period of observation manifestly increases the mortality figures by including late ultimate deaths.

A fact of interest is brought out strikingly by reducing to graphic form in Chart 2 the figures of Table 2, showing the percentage of influenza cases that developed secondary pneumonia and the percentage of such secondary pneumonia that resulted in ultimate death, progressively, week by week, throughout the epidemic. It is thus seen that with the course of the epidemic there took place a progressive increase in the percentage of pneumonia incidence and at the same time a progressive decline in the percentage of pneumonia mortality. It would be interesting to know whether a similar relation was shown in other camps. It would also be of interest to know the explanation of these conflicting tendencies. Why did a steadily increasing proportion of influenza cases develop secondary pneumonia, and why did this increasing pneumonia incidence result in a decreasing pneumonia mortality? One might reasonably suppose that a tendency to increase in pneumonia incidence would be accompanied by at least a maintained mortality rate. The agent of infection increased its ability to infect but lost its virulence to kill. It might occur to one that the diminishing mortality might be explained by a gradual change taking place during the course of the epidemic of the species of the infecting organisms causing pneumonia, but this idea finds no support in the facts, as exhibited in Table 3, showing the organisms prevailing in the sputums of pneumonia patients in the earlier and later periods of the epidemic. There was no notable change exhibited. Whatever the explanation of the fact may be, it is plain that one caution should be taught thereby, namely, that claims of therapeutic efficacy should not be based on favorable results obtained during the declining period of the epidemic. In our own cases the method of treatment was uniform and unchanged from first to last, and therefore played no part in explanation of the progressive decline of mortality. The pneumonia mortality declined steadily from 43.2 per cent. in the first week to 8.33 per cent. in the ninth week, less than one-fifth the earlier rate.

A few clinical features of the epidemic may be mentioned specifically:

The treatment of influenza was purely symptomatic. No vaccines or serums were used either for prophylaxis or treatment.

The mortality from influenza (all caused by secondary pneumonia and its complications and sequelae), calculated up to Jan. 1, 1919, was: for the period of the primary epidemic (from September 13 to October 22, inclusive), 6.58 per cent; for the period of the late or secondary epidemic (from October 23 to November 30, inclusive), 4.18 per cent.; for the whole period of the primary and secondary epidemics (from September 13 to November 30, inclusive), 6.30 per cent.

TYPE OF DISEASE

There was only one type of influenza seen, namely, the respiratory type. The nervous, the gastro-intestinal, and the febrile types, commonly described in previous epidemics, were conspicuous by their absence as special types. Nervous manifestations were prominent but always were associated with respiratory symptoms. Meningitis occurred in only one case, secondary to pneumonia (pneumococcus Type IV). Meningismus simulating meningitis occurred in a few cases, always in association with pneumonia except in one uncomplicated case of influenza. The cell count of the spinal fluid in meningismus was normal. Severe gastro-intestinal symptoms were infrequent or rare. In only occasional cases was there marked abdominal pain, in a few instances associated definitely with acute or subacute appendicitis. Taking the cases as a whole, we found that complications were infrequent with the notable exception of the one predominant complication, pneumonia, and its sequelae.

Recurrent or secondary attacks of influenza were very rare, most instances of supposed recurrent attacks in reality being attacks of the previously mentioned infectious tonsillitis and sore throat, which led to many errors of diagnosis. Secondary rises of temperature of short duration, within a day or two after primary defervescence, occurred occasionally without complication, but were always regarded as presumptive evidence of the onset of bronchopneumonia and this presumption was almost invariably confirmed by the subsequent course if the secondary rise of temperature continued beyond twenty-four hours or was not explained by other manifest complication.

Secondary bronchopneumonia, with its complications and sequelae, was the sole cause of death in the influenza epidemic. The mortality for pneumonia (including its complications and sequelae) secondary to influenza, calculated to Jan. 1, 1919, was as follows: for the primary epidemic (from September 13 to October 22, inclusive), 31.19 per cent; for the late or secondary epidemic (from October 23 to November 30, inclusive), 14.71 per cent; for the whole period of the primary and secondary epidemics (from September 13 to November 30, inclusive), 28.70 per cent. All delayed deaths occurring up to Jan. 1, 1919, are included in the above figures.

TREATMENT

The treatment of pneumonia was not changed throughout the epidemic. No vaccines were used and serums only in a few cases in which the sputum typing revealed infection with pneumococcus Type I.

All patients with pneumonia from the beginning to the end of the epidemic (and since that time up to the present) were given tincture of digitalis in substantial doses, larger than commonly employed. The usual single dose was a dram or a dram and a half, repeated three times daily until from five to six doses were given within a period of from thirty to thirty-six hours, the medication being started as soon as the diagnosis of pneumonia was positive, probable or even

---

* The last column represents the number of deaths listed by day of death, irrespective of the day of origin of the influenza resulting in death. The second, third and fourth columns should be read with reference to the first column, being arranged to show the number of cases of influenza of corresponding date that resulted at any subsequent date, up to Jan. 1, 1919, in pneumonia, pneumonia and empyema, or death. This arrangement indicates, by reading the columns crosswise, the subsequent complications and outcome of each day's admissions of influenza patients. It will be observed that this method of presenting the statistics of the epidemic differs from the method commonly followed, namely, the mere listing of influenza, pneumonia and deaths by date of occurrence. The method here used appears to be the logical method, pursuing daily admissions of influenza through their entire subsequent course and complications to their final outcome by cure or death. It is of little statistical value to know merely how many cases of pneumonia or death happened to fall on certain days in the epidemic, but it is of great statistical value to pursue daily admissions of influenza patients through their subsequent course and thus to establish the comparative degree of severity of the epidemic at different stages in its progress.

likely. The patients received, therefore, from 300 to 500 minims, average about 350 or 400 minims, of the tincture, representing one-tenth strength of the crude drug. As a result of this large dosage we saw very few instances of bradycardia below 60 per minute or of recognizable arrhythmia, though caution was observed in following the pulse of every patient. Having employed these large doses of digitalis in the treatment of approximately 2,000 cases of pneumonia of different types during the past seven months, we feel justified from our experience in emphasizing the conviction that they are not dangerous or likely to produce serious disturbance of the heart, at least in the class of patients that we have treated, that is, selected young men of military age, generally with sound vital organs. On the contrary, our belief is firm that these large doses of digitalis are well tolerated in pneumonia, and that they slow and strengthen the heart action and save lives. When death impends, the pulse usually maintains a good quality almost to the end. Whether patients of more advanced years with impaired vital organs would respond so favorably to similar treatment we are not justified in assuming, but observing proper caution, we would have little hesitation in treating them similarly. In addition to digitalis the treatment employed was symptomatic.

DIAGNOSIS OF PNEUMONIA

As previously stated, all deaths following influenza were attributable to secondary pneumonia and its complications and sequelae (empyema, pericarditis, meningitis, etc.). Pneumonia, therefore, was the one danger that threatened life. As pneumonia developed in over one fifth of all cases of influenza, and killed almost one third of those it attacked, its early recognition was imperative if therapy was to possess any value.

TABLE 2.—PERCENTAGE OF PATIENTS ADMITTED FOR PRIMARY INFLUENZA WHO SUBSEQUENTLY DEVELOPED PNEUMONIA, COMPARED WITH THE PERCENTAGE OF PNEUMONIA MORTALITY AND GROSS INFLUENZA MORTALITY RESULTING FROM CORRESPONDING GROUPS OF CASES; ABSTRACTED FROM TABLE 1*

* Note the general tendency, with the progress of the epidemic for the percentage of pneumonia incidence to increase and of pnumonia and influenza mortality to decrease.

The early diagnosis of the kind of bronchopneumonia seen during the epidemic was a severe test of the training, judgment and patience of those responsible. The criteria brought from civil practice had to be unlearned and other standards adopted. To be sure, cases with outspoken physical signs and symptoms did occur, but they were conspicuous by their infrequency. The patients in general presented few of the usual symptoms and signs of frank pneumonia. Wretchedly sick and prostrated from the primary influenza, they either progressed continuously and insidiously from influenza into pneumonia, or after the interval of a day or perhaps a few days of convalescence from influenza, a recurrence of high temperature and general symptoms of illness occurred and pneumonia was established. With the absence or paucity of physical signs in the chest, pneumonia was suspected or diagnosed on the basis of this suggestive order of events: A high or irregular temperature continued over more than the usual three or four days of influenza generally indicated pneumonia; a high temperature that recurred and continued for more than one day after defervescence from influenza also usually meant pneumonia, unless clearly explained by other known complications. We learned to be guided to the diagnosis of pneumonia by the appearance of the temperature chart and this guide seldom led astray.

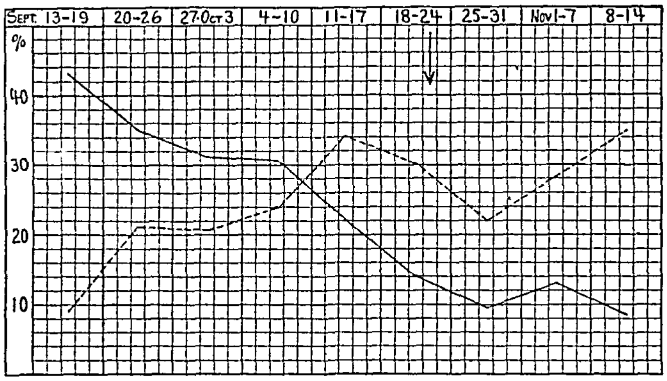

Chart 2 (illustrating Table 2).—Percentage of cases, week by week, admitted for primary influenza, in which cases pneumonia subsequently developed, compared with the percentage of pneumonia mortality from the corresponding groups of cases: broken line, percentage of influenza patients developing pneumonia; solid line, percentage of pneumonia cases resulting in death; the arrow indicates end of primary epidemic, Oct. 22, 1918.

The patient looked sick and suggested a serious condition. His pulse and respiration rates were low relative to temperature and offered not much help in diagnosis. The patient had no grunting or stertorous respiration. He breathed quietly, softly. He had no pain in the chest or it was slight. His nostrils did not dilate in breathing, and he had no telltale herpes about the lips or face. His face was often cyanotic, sometimes ashy, sometimes just pinched looking. He expressed no pain or suffering. If his mind was clear he expressed a sense of euphoria, or of unnatural unrealization of his condition, which in particular marked the advanced stages of the disease. There was a striking tendency toward mental hebetude, drowsiness, wandering and delirium. All of these mental features increased with the progress of the disease. The leukocyte count was usually low, below 10,000, and failed as a guide.

In making the early diagnosis of pneumonia, then, we were guided first by the criteria above described, of temperature, general appearance and condition in relation to preceding influenza.

The physical signs of pneumonia in the earlier stages were either lacking, slight or equivocal. This cannot be emphasized too strongly and especially to civil practitioners, who have not had the exceptional opportunity offered in the military hospitals of studying this type of pneumonia in hundreds and thousands of cases. Nor have we seen this fact sufficiently presented, although usually referred to, in the reports on the epidemic published in the journals from the great military hospitals and camps.

In examining the chest for physical signs of pneumonia we learned to save time and patient by omitting percussion or reserving it to the last. It was the most unreliable of all signs. We proceeded directly to a hasty auscultation of the vocal fremitus of the back of the chest and found this gave the most constant evidence of localization, usually by mere intensification of normal vocal fremitus. If a distinct bronchial or nasal quality were added to the intensified vocal fremitus, which was the exception in the early stages, the diagnosis was fairly secure.

Our next procedure was to auscultate the forced breathing sounds of the entire back of the chest or that portion only in which localization of increased vocal fremitus had been found. Bronchial or bronchovesicular breathing was usually absent or perhaps suggestive but doubtful. In the exceptional case only was it unequivocal. The rule was to find only some degree of intensification of normal breathing, which left one in doubt as to its significance. Later true bronchial breathing was usually found, but seldom in proportion to the involvement of the lungs.

TABLE 3.—RESULT OF EXAMINATION OF SPUTUMS IN PNEUMONIA CASES

Organisms Found by the Avery Cultural Method *	Period of Primary Epidemic, Sept. 13-Oct. 22, Inclusive		Period of Secondary Epidemic, Oct. 23-Nov. 30, Inclusive		Period of Entire Epidemic, Sept. 13-Nov. 30, Inclusive

Staphylococcus	12	1.5	5	3.4	17	1.8
Total	766		145		911	

* Where two or more organisms were found only the more virulent one is included in the table.

† Bacillus influenzae was found with greater frequency as the technic was improved and as greater care was taken in searching for it. Except in the cases given in the table it was always associated with other organisms, notably pneumococcus Type IV. Toward the end of the epidemic it was recovered in 38 per cent. of cases.

Next we asked the patient to cough deeply while we auscultated the area of suspicion. This often but not always brought out a localized cluster of fine râles. In some cases such sharply localized groups of râles were the only sign at a single examination.

The three signs of localization were, then, in order of importance and frequency: (1) increased vocal transmission, with or without bronchial quality; (2) clustered fine râles, especially excited by coughing; (3) intensification of normal breath sounds, with or without the addition of bronchial or bronchovesicular quality. The degree of prominence of any one of these signs and the degree of combination of more than one of them in the same area determined the degree of value to be attached to the signs as evidence of pneumonia. It was remarkable how often all signs were absent at a single examination or how often some single sign only was present in such minor degree as to be unconvincing of its significance. But by experience we learned how to piece together the general symptoms and the minor localizing signs into a probable or fairly secure diagnosis, to be confirmed by subsequent examinations in the course of the disease or by the evidence of the roentgen ray.

A point of special interest in the physical examination, which occurred frequently and which we have not seen mentioned, was the absence of bronchial vocal fremitus or bronchial breath sounds during a careful examination covering several minutes, and then the abrupt appearance of such signs even in marked degree, perhaps during a few breaths only, followed again by their disappearance. With experience we found that we could sometimes provoke such abrupt changes, by one maneuver or another, such as turning the patient from side to side or placing him upright or by a deep breath or a cough. In doubtful cases we never omitted the trial of these maneuvers and were frequently rewarded for the effort.

Percussion dulness, as a localizing sign, was of very slight value, seldom if ever being a guide in early diagnosis and being notably unreliable as a guide to the extent of lung involvement in the advanced stages, as tested by necropsy findings. While the same was true more or less for all signs, as tested at necropsy, this held true for percussion evidence in a special degree. The reason for this was made plain at necropsy by the striking degree of acute compensatory emphysema of the lungs, both in the involved and uninvolved portions. Instead of transmitting a dull note, a consolidation often actually misled by yielding hyperresonance on percussion.

Palpation seldom offered any evidence of particular value, especially when it was most needed for early diagnosis.

In looking for evidence of pneumonia in its early stages, it was useless to examine the apexes of the lungs or the front of the chest. The early localization was never found in those portions, but almost without exception near the roots of the lungs along the inner margin of the back and extending therefrom in other directions, especially downward into the bases. Much time in examination is saved by a knowledge of this fact. Early roentgen-ray examination of patients confirmed fully this almost unbroken rule.

As to the side of the chest most often involved in the early process, no striking difference was observed either by general or by roentgen-ray examination though possibly the right side preponderated slightly.

The roentgen ray was used for aid or confirmation in 566 cases, always in doubtful cases. The evidence that it afforded proved reliable in the main, and its assistance was of the greatest value. Exceptionally, it failed to accord with definite physical signs and showed a negative chest in a positive pneumonia. The reverse was more often true, the roentgen ray showing a consolidation in the absence of physical signs.

Among the 1,526 cases of pneumonia there developed, up to Jan. 1, 1919, only twenty-seven instances of empyema, making an empyema incidence of 1.76 per cent., calculated for pneumonia. Eight of the twenty-seven patients died, six in the active period of pneumonia, two at a later period. Recently we have seen empyema develop six months after influenza pneumonia, the necropsy showing unilateral fibrosis and contraction of the lung, purulent bronchitis and small multiple abscesses.

During the winter months following the epidemic we observed in patients admitted to hospital few late complications and sequelae that could be attributed to preceding influenza and pneumonia. This observation was rather surprising, and contrary to expectation. In a few instances we have seen chronic bronchitis with cough and râles persist for fully six months after pneumonia, without much impairment of general health. Such signs naturally suggest a suspicion of tuberculosis, but this was apparently excluded.

The first fifty fatal cases were subjected to necropsy without selection and thereafter only occasional cases were brought to necropsy for special reasons. The findings were the same as reported from other camps, in general extensive, often confluent, bronchopneumonia with marked compensatory acute emphysema.

The bacteriologic and pathologic studies of the disease disclosed no facts of peculiar importance and determined nothing as to the real cause of the disease.

SUMMARY

1. The epidemic of influenza at Camp Upton in its clinical aspect and severity was the counterpart of the disease as reported from the other great camps in the northeastern section of the United States.

2. Secondary bronchopneumonia was the one predominant complication. Bronchopneumonia with its complications, chiefly empyema, was the sole cause of death. Empyema was encountered in only 1.76 per cent. of pneumonia cases.

3. The statistical tables and graphic charts are arranged to show, by reading the tables crosswise and the charts up and down, the ultimate outcome (complications and deaths) that resulted from the original daily admissions of influenza, calculated up to Jan. 1, 1919, irrespective of the date on which the complications or deaths happened to fall. This arrangement portrays the relative severity of the disease at all stages of its progress.

4. Chart 2, based on Table 2, shows the curves of pneumonia incidence rate compared with pneumonia mortality rate, expressed in percentage, resulting from admissions of primary influenza week by week through the epidemic. This chart brings out visually the interesting and unexplained fact that the pneumonia incidence rate increased while the pneumonia mortality rate decreased progressively and strikingly from the start throughout the course of the epidemic. This fact, if confirmed in other military camps, tends to invalidate claims of special therapeutic efficacy based on results obtained after the early part of the epidemic, during a period of natural decline of mortality.

5. The use of digitalis in large doses at the beginning of pneumonia, employed as routine practice, resulted in no observed harmful effects in any case, and proved of distinct benefit. The pulse remained slow and regular, even in fatal cases, to the end.

6. The early diagnosis of the type of bronchopneumonia secondary to influenza seldom rested on clear physical signs in the chest. The physical signs were evasive and slight and needed to be carefully sought for and combined with the other clinical data or the roentgen-ray findings in determining an early diagnosis. The criteria for diagnosis are described in some detail.

7. Toward the end of the epidemic of influenza there was added a new affection, occurring in epidemic form, that symptomically closely resembled influenza, needed careful differentiation, and led to much confusion and error in diagnosis—a peculiar form of infectious tonsillitis, characterized particularly by swelling of the tonsils and a membranous deposit on them. This affection has been the chief cause of admission to hospital from late November to the present time (April 1, 1919). A similar affection prevails widely in other places and is masquerading in vital statistics under the guise of influenza.

HYPOPHYSIAL DYSTROPHY IN HYDROCEPHALUS

AUGUST STRAUCH, M.D.
Attending Physician at the Cook County Hospital, Children's Department
CHICAGO

Besides primary disturbances of the hypophysis itself, such as tumor, hypoplasia, etc., there are a number of intracranial conditions, either in the vicinity of the gland or more remote, that, directly or indirectly, may lead to interference with its function, resulting in the development of pituitary adiposity. Not only neighboring new growths, but also severe hydrocephalus with dilatation of the third ventricle, of whatever origin, may exert deleterious pressure on or obstruct the hypophysis and thus interfere with its normal function.

Harvey Cushing[1] remarks that secondary changes probably occur in the pituitary body in every case of increased intracranial tension, often with gross deformity and resultant functional disturbances which frequently elicit recognizable clinical manifestations. The scanty literature on the relation of hydrocephalus to the pituitary gland has been reviewed by the above named writer and in THE JOURNAL by Pollok.[2]

As an instance of conspicuous manifestations of hypophysial dystrophy in connection with a hydrops ventriculorum, the following case of a patient admitted to the Cook County Hospital, Oct. 15, 1918, may be reported:

REPORT OF CASE

History.—The girl, F. M., aged 8 years, 10 months, had always been a strong, bright child and had had a somewhat large head. When 16 months old, she is said to have weighed 36 pounds. After December, 1917, the girl often came home from school with wet clothes, being unable to hold the urine long. She drank much water and had to urinate frequently. She had, during the winter of 1917-1918, daily attacks of supra-orbital headache, sometimes accompanied by vomiting, with occasional dizziness. Her appetite grew ravenous, especially for bread. Polydipsia and polyuria lasted up to the time of admission to the hospital.

In February, 1918, her body weight, which was then 72 pounds, began rapidly to increase, and she became obese. At first irritable and "nervous," she soon became apathetic and sleepy, quite in contrast with her previous alertness, and she ceased making progress in the school. She tired very easily, and had difficulty in keeping her balance; walking became difficult, and she finally had always to be led by her mother. After the end of February, she was unable to attend school. The upper extremities became weak, trembling, awkward and ataxic. During that year she grew rapidly—"one could see her grow;" there also occurred a marked aggravation of preexisting genua valga and a striking enlargement of the head, so that it became difficult to purchase a hat large enough for her.

---

[1] Cushing, Harvey: The Pituitary Body and Its Disorders, 1911.

[2] Pollok, L. J.: Hypopituitarism in Chronic Hydrocephalus, J. A. M. A. 64:395 (Jan. 30) 1915.

Physical Examination.—Physical examination revealed a well developed, obese girl (Fig. 1), weighing 95 pounds, body *length 135 cm.*, distance of lower edge of symphysis *from* floor 66.5 *cm.* There was a *marked* development of adipose tissue, especially on the neck, in the region of the angulus mandibulae, of the pectoralis muscles, on the lower part of the large protruding abdomen, and on the mons veneris, which was separated from the abdomen by a deep furrow. There was also around the hips and on the upper part of the thighs an excessive amount of adipose tissue. The circumference of the chest in the nipple line was 74 cm., of the abdomen in the umbilical line 83 cm., and around the trochanters 82 cm.

The general integument and mucous membranes were of a healthy color; the skin was very soft, delicate, smooth and without perspiration. The body was covered with a very fine lanugo, that on the outer aspect of the forearm being more developed. The labia *majora* were much developed, large and covered with dense lanugo and a few darker, longer and thicker hairs. The hair of the scalp was abundant and long. The skull was large, its horizontal *circumference* being 59.5 cm.; the measure from the meatus auditorius of the one side to that of the other was 39 *cm.* The *skull in the* region of the anterior fontanel was thinned, distinctly yielding on pressure, and tender.

The face was very fat. The veins of the right upper *lid* and temple were bulging, those of the left *upper* lid less so. There was slight exophthalmos. The pupils were large, reacted at times sluggishly, at other times promptly. The eye fundus was *normal*. The hands were graceful, somewhat pudgy, very soft and smooth, the fingers being somewhat tapering. The *nails of* both thumbs had a normal lunula, *the index* fingers a hardly visible lunula, while the other fingers had no crescent at all. The hands and feet were cold. Genua valga and pedes valgi were present.

There was motor ataxia of the arms, which on some days was very pronounced, on other days demonstrable only with finer tests. The gross muscular power of the arms and legs was much reduced. There was no spasticity. The patient was able to sit freely without ataxia, but was unable to stand or walk without support, and swayed and fell if not held up. The general asthenia forced her to spend all her time in bed or on a chair. The patellar reflexes were increased, that on the right side being more pronounced. Babinski's reflex was positive. There was ankle clonus, especially on the right side. There was involuntary micturition. The Wassermann test was negative. The systolic blood pressure was 95, diastolic 65. The pulse was between 100 and 110. The intellectual faculties were much impaired, and the *school* learning was very deficient. On three *occasions*, 100, 150 and 210 gm. of glucose were given by *mouth* without causing glycosuria.

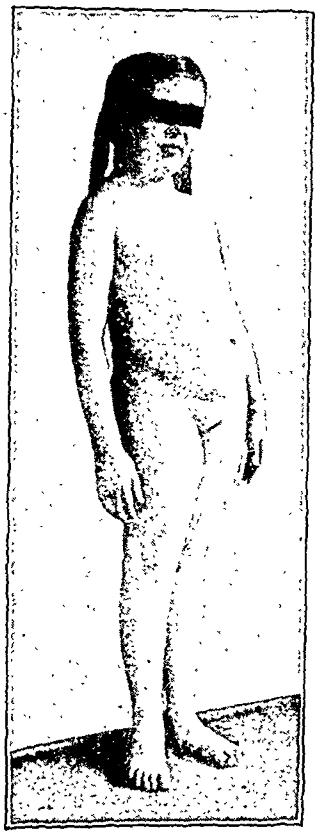

Fig. 1. — Hydrocephalus, accompanied by hypopituitarism.

The roentgenographic examination (Fig. 2) revealed a greatly enlarged, shallow sella turcica and reduced clinoid processes. The stereoplates of the entire skull showed a hydrocephalus with open coronal suture and marked digitations of the frontal bone.

The girl gained 3 pounds in the first two weeks of observation (98 pounds). The reflexes were changeable, the ankle clonus often being absent. Later incontinentia alvi supervened. By the end of November, bilateral *optic* neuritis was found, the vision of both eyes being 20/30. The hairs on the labia majora increased somewhat in size and number. The sensorium was free, the girl friendly and kind; however, she was quiet and often languid and drowsy. During the last three months of her life she had periods of marked apathy, even torpor, when suffering from measles, otitis media suppurativa acuta and bronchopneumonia, to which she succumbed, March 2, 1919. She grew 3 cm. in height after admission to the hospital and lost in body weight during the last few weeks.

Postmortem Findings.—From the pathologic report, for which I am indebted to Dr. F. H. Stangl, resident pathologist at Cook County Hospital, the following features may be mentioned here:

The calvarium measures 3 mm. in *thickness*; its sutures are only fibrous. The *brain* is large, owing to an increased amount of ventricular fluid. The convolutions are markedly flattened. The brain is 16.1 cm. wide, 20.3 cm. long and 10.1 cm. high, and, with its contained fluid, weighs 2,190 gm. The infundibulum is 12 mm. long and kinked on itself. The hypophysis is but slightly flattened and measures 7 mm. by 11 mm. by 16 *mm.* Serial coronal sections of the brain reveal greatly dilated ventricles with reduction in the brain substance surrounding them. The *right lateral* ventricle measures 4.5 cm. transversely *and* 6.5 *cm.* vertically, the left one 3.8 and 6.5, and the third ventricle 2.0 and 2.5 cm., respectively. There is a shifting of the parts of the brain, especially of the occipital half, with *resulting* malposition. The aquaeductus Sylvii is entirely closed by compression, and the right hemisphere *of the* cerebellum has undergone decrease *in size* from pressure.

The internal genitalia *reveal* no gross *changes*. The body of the uterus is 3 *cm.* long, 1.5 cm. wide at the fundus and 0.5 cm. thick. Sections of the hypophysis stained with *eosinhematoxylin* have been examined microscopically by Dr. G. B. Hassin with the following result: The three portions of the organ were distinctly shown; they are surrounded by a connective tissue membrane consisting of collagen fibers with well stained oblong nuclei. The anterior or glandular part exhibited *numerous* acini, some of which appeared more densely stained than others. The epithelial cells of the acini or alveoles showed a large, well developed granular cytoplasm, containing an eccentric nucleus Some *epithelial* cells were unusually large, exhibiting two or more nuclei. *In other acini* which were quite numerous the epithelial cells were very pale, homogeneous, irregular in shape, but with a distinct, well stained nucleus. Such cells often merged together forming a large colloidal mass containing several nuclei. The colloid often totally obliterated the acini, or filled up their *lumina*, sometimes appearing as very large diffuse masses or small globules freely scattered in the interalveolar spaces. The blood vessels were dilated and greatly congested; some were partially or totally filled with a colloid substance. There were to be seen foci of hemorrhages in the tissue of the capsule and between the latter and *the* glandular tissue. The *pars* anterior of the hypophysis was in the center of the section—isthmus-like—*continuous* with the posterior portion, which appeared reticular, *the stroma in the* area of junction showing much wider meshes *than* in the rest of the posterior lobe. There were to be seen a few congested capillaries and still fewer colloidal bodies.

The lateral portions between the anterior and the posterior *lobes of the* hypophysis (of the pars intermedia) *were occupied* by strikingly large cuneiform clefts or rather cystic formations lined with epithelial cells and entirely filled with colloid. *The latter* contained cellular masses with distinct nuclei, *situated here* and *there*, but as a rule near the *margins of* the cystic clefts. These two colloidal formations can be seen with the naked eye, the larger one measuring 1.5 *mm. in width* and *3* mm. in length. The pathologic changes can thus be summed up as subcapsular hemorrhages, excessive hyperemia and *vascularization* of the anterior lobe, hyaline or colloidal thrombosis and excessive amounts of colloidal acini. The findings so far give no exact idea of the presence or absence of any pathologic process that caused the hydrocephalus. Further studies are being carried on, and a more complete report, especially of the histopathology of the brain is forthcoming, being in preparation by Dr. G. B. Hassin.

COMMENT

Certain features of the anamnesis of the case are suggestive and a part of the clinical syndrome is quite characteristic of hypophysial dystrophy. The manifestations of the latter, however, must be distinguished from those of internal hydrocephalus. The rapid development of adipositas nimia, with eunuchoid localizations, and the high tolerance for glucose, indicate constitutional, metabolic changes—such as are observed in functional deficiency of the posterior lobe of the hypophysis. The delicate skin, the lack of perspiration and the arterial hypotension likewise point to this organ. On the other hand, the abnormal increase of the size of the skull, with thinning of the region of the anterior fontanel, and the marked remissions and exacerbations of the nervous disturbances, leave no doubt about the existence of hydrocephalus internus. Its causal agency, however, cannot be ascertained clinically beyond dispute, the differential diagnosis considering an "idiopathic" hydrocephalus, or rather the exacerbation of a previous hydrops ventriculorum, and a possible distant obstructive tumor without focal manifestations.

The presence of the hydrocephalus gives satisfactory explanation of dystrophy, through the assumption of a pressure lesion of the hypophysial apparatus, and, with the absence of optic nerve disturbances, even as late as at the time of admission, militates against the assumption of a tumor of the hypophysis itself. The radiologic findings are in accord therewith, the shallow dishlike dilatation of the entrance of the sella turcica being merely a partial manifestation of the cranial changes that are due to the general increased intracranial tension.

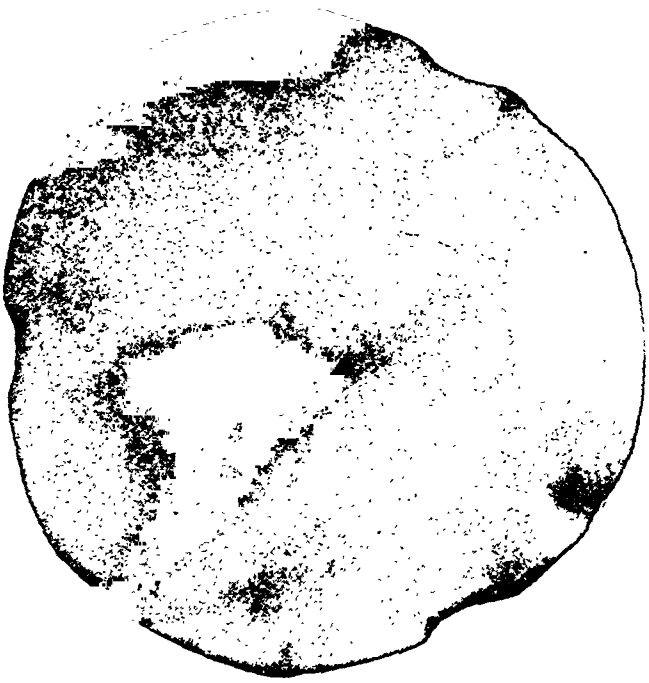

Fig. 2.—Roentgenogram of sella turcica and clinoid processes in a case of hypopituitarism.

Cushing at first explained the pituitary deficiency in hydrocephalus as due merely to the dilatation of the third ventricle, with consequent flattening of the gland. Since the demonstration of a possible discharge of the posterior lobe secretion into the cerebrospinal fluid, he sees in the stasis of the cerebrospinal fluid an equivalent in its effect to an experimental obstruction of the stalk, or to a compression by an immediately superimposed infundibular tumor. In connection with his ideas it is noteworthy that in our case a slight flattening of the gland and kinking of the infundibulum were found postmortem, according to the report given me.

Polyuria and polydipsia, which for a time were so marked in our case, have not infrequently been noted by other authors as a temporary symptom in hypophysial dystrophy, and in a few cases a serious diabetes insipidus was the predominant feature. It also has been encountered for a period as an after-effect of surgical operations in the hypophysial region, even of simple sellar decompression (Cushing). The occurrence of polyuria observed by Schaeffer[3] in bloodless, mechanical or chemical irritations of the hypophysis, and the well established diuretic effect of the extract of the nervous lobe, combine to indicate the cause of this clinical symptom to be an increased secretion resulting from irritative conditions, such as pressure, inflammation, etc.

Thus a state of initial stimulation of the posterior lobe in our case may be assumed preceding its inhibition or obstruction. The persistence of polydipsia, however, during the period of well developed adiposity, the latter indicative of hypofunction, cannot, of course, be attributed to a simultaneous hyperfunction; it must be explained on a different basis. We may consider it merely a habit formed during the illness. Several circumstances indicate this; the excessive drinking of water, for instance, had entirely lost its initial compelling character and its degree; it became easily controlled by persuasion, was subject to occasion and absent during the stay in the hospital.

On the other hand, marked polyuria has been observed also in tumors (gumma) in the vicinity of the hypophysis and in various affections of the brain stem (chiasma, subthalamic region, etc.); it likewise has been produced by irritation of certain parts in the medulla oblongata.

The polyphagia, repeatedly mentioned in the literature, has been attributed to posterior lobe insufficiency. If we interpret the rapid growth of the patient, the advanced development of the labia majora, and the growth of hair on the labia majora in the light of the present preponderant evidences of the function of the parts of the hypophysis, we may possibly have here an example of activation and hyperfunction of the anterior lobe, combined with posterior lobe insufficiency (dyspituitarism, Cushing). This unusual type differs thus from the common type (Froehlich's[4]) of hypophysial dystrophia adiposogenitalis, which is characterized by undergrowth and sexual hypoplasia due to simultaneous anterior lobe inhibition. Somewhat similar instances of dyspituitarism are those of Neurath[5] and Case 34 of Cushing.

The disturbance of micturition and defecation finds its ready explanation in the large hydrocephalic effusion, with pressure lesion of the corresponding cerebral districts. Bladder disturbances, which, according to Frankl-Hochwart and Froehlich,[6] are not infrequently observed in hypophysial dystrophy, have been explained mostly by compression of the pes pedunculi by a growing tumor of the pituitary body. However, both authors consider also the possibility of the reduced function of the posterior lobe and the lack of the pituitrinum infundibulare being a responsible factor.

The presence of a marked degree of hydrocephalus in our case renders it futile to distinguish the psychic alterations of hypophysial origin from those due to the ventricular effusion.

The supervening optic neuritis would have made surgical interference urgent. Balkenstich operation after Anton and Bramann was contemplated as the simplest decompression operation for the hydrocephalus, with the possibility in view of thus relieving and reactivating the pituitary body. The intercurrent diseases, however, rendered it impossible.[7]

THE SURGICAL TREATMENT OF RHINOPHIMA

JOSEPH E. FULD, M.D.
Attending Surgeon to Park Hospital; Instructor in Operative Surgery, College of Physicians and Surgeons, Columbia University; Assistant Visiting Surgeon, City and Gouverneur Hospitals
NEW YORK

Rhinophima is the most advanced stage in the development of acne rosacea, characterized by marked hypertrophic changes in the cutaneous and subcutaneous tissues of the nose, producing a firm, reddish or purplish lobulated, and, in extreme cases, pendulous tumor masses. This condition is frequently so disfiguring and repulsive as to prevent the person afflicted with it from earning a livelihood or mingling in society, and it is in just such cases that surgery offers the only means of relief.

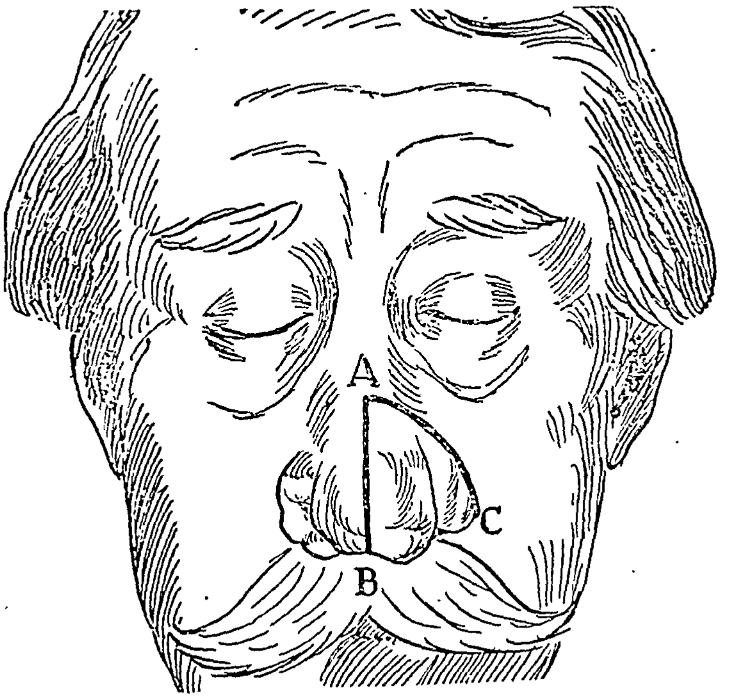

Fig. 1.—Incision made in removing the left half of the growth: *A B*, midline incision made down to the cartilage; *A C*, lateral incision encircling the growth.

The pathologic changes which lead up to this condition may well be divided into three stages. The first stage is marked by a simple venous engourgement. The second stage shows the veins and the capillaries permanently enlarged. In the third stage, there is an enormous hyperplasia of the connective tissue elements of the skin, and the sebaceous glands are so enlarged that the nose presents a honeycombed and unsightly appearance.

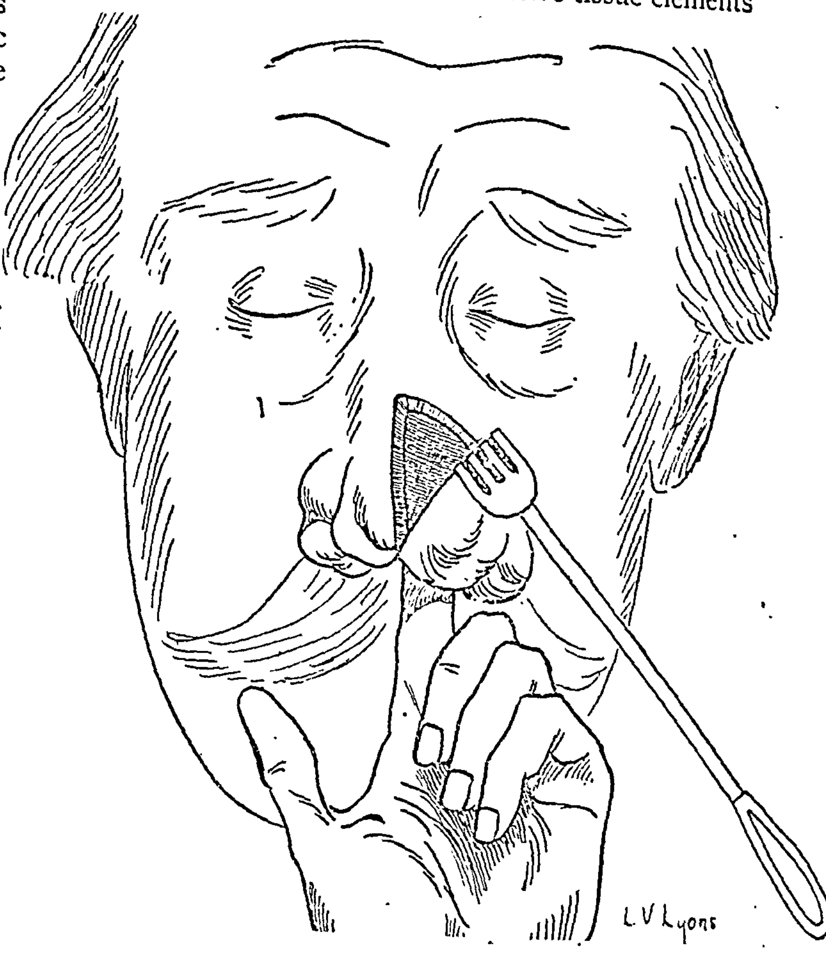

Fig. 2.—The procedure for removing the growth.

TREATMENT

It is at this stage that the electric needle, ointments and the roentgen ray are no longer of therapeutic value, but where surgery is the only cure. When the tumors are pedunculated, a condition which frequently occurs, their removal requires no special description. There is, however, a marked difference in the operative procedure involving extensive hypertrophy without pedunculation, as in the case of the patient on whom I operated, as shown in the accompanying photographs.

Instead of removing the tumor masses in one piece, in my recent cases, I excised first one half then the other half of the growth, making the operation much easier to perform.

OPERATIVE PROCEDURE

Under general anesthesia, an incision is made down to the cartilage in the median line of the nose, as shown in Figure 1, from *A* to *B*, and a second incision all around the growth from the midline outward from *A* to *C*. The forefinger of the left hand is now inserted into the left nostril, with the palmar surface forward, as a guide. The median edge of the tumor mass is grasped with mouse-tooth forceps (assistant to hold these), and all the diseased tissue, including the entire left lower half of the nose, with the whole thickness of the skin, is dissected off with a knife, the bony and cartilaginous framework of the nose being exposed. The hemorrhage is controlled by pressure with hot pads or forceps and ligations, if necessary. The foregoing steps are repeated on the right side. It is important to leave a little skin near the opening of the nares to avoid subsequent contracture with the resulting stricture.

[7] In addition to the references already given, the following will be found of interest.
Falta, W.: The Ductless Glands (translation from the German).
Strauch, A.: Infantilism, Am. J. M. Sc., 148: 247, (Aug.) 1914.

The final step in the operation demands considerable care, as the skin graft should be applied in one large piece if possible, and the fairly thick graft which was used in my case has contributed very largely to the striking similarity in the appearance of the new covering of the nose to that of the face in general. Short nasal tubes are now inserted into the nostril, and the nose dressed by carefully covering the graft with several layers of silver foil. A gauze dressing is applied, which is held in place with adhesive plaster, and allowed to remain undisturbed for six days. As all my skin grafts were successful, no further aftertreatment was necessary. In cases of this sort, in which the condition so seriously affects the appearance of the patient and the results of the operation are usually both successful and gratifying, it seems surprising that an operation so simple, as here described, has not been resorted to more frequently.

The Education of the Expert.—The interests of the public and of the nation will be served if all important problems, public as well as private, are in the hands of experts for solution. In administration, legislation, the public health service, agriculture, all branches of engineering, commerce and education, practical problems are continually arising and on the correct solution of these problems depends the welfare of many individuals and even of the nation itself.—Dr. P. G. Nutting, *Scientific Monthly*, November, 1918.

STERILITY OF CATGUT

T. BUTTERFIELD

AND

LEO F. ELY

Lieutenants, S. C., U. S. Army

The writers were assigned by the Surgeon-General to make bacteriologic examination of catgut manufactured for the Army during the period from Dec. 11, 1918, to May 3, 1919, and a special opportunity was, therefore, presented to make extensive study of the sterility of the commercial catgut as manufactured by the particular firms in Chicago that were concerned with the Army contracts. Approximately 15,000 tubes, selected at random, representing a total output of 5,000,000, were examined. The total number of contaminated tubes found was 1,518, or 11 per cent.

Through the courtesy of the manufacturer it was permitted to vary the sterilization process under official government supervision until a more dependable process was found whereby a sterile product would be furnished. This experimental process will be described later. The method followed in making the bacteriologic examinations is first described; the process of sterilization used by the manufacturer, the difficulties of this process, and the advantages suggested as a result of our experiments are discussed later.

METHOD OF THE AUTHORS

An inspector representing the United States Appraisers Stores collected 100 tubes of catgut from each autoclave, and these were equally divided between the two bacteriologists. In order to prevent any possible sources of extraneous contamination being carried into the culture tube from the outside of the tubes containing the catgut, the tubes from each sterilizer were placed in a beaker and given a thorough washing in petroleum ether to remove all oil from the outside. After this preliminary precautionary measure the tubes were allowed to stand in a 1:200 solution of mercuric chlorid over night. The actual work of transferring the catgut from the tubes to the culture broth was done under a small glass cage, placed in a small room. The room and cage were wiped down each morning with a 1:1,000 solution of mercuric chlorid.

The following morning the tubes were lifted with sterile forceps from the mercuric chlorid solution and dipped quickly into boiling water to wash off the adherent mercuric chlorid. The empty end of the tube was heated in a small flame and the end broken off with sterile forceps. The coil of catgut (average length 18 inches) was pulled with a small pair of sterile scissors part way out of the broken end of the tube and the coil was clipped in two, thus dividing the catgut into pieces about 2 inches long. The catgut was then taken up with the scissors and dropped into a sterile, cotton-stoppered Erlenmeyer flask containing about 120 c.c. of sterile water. The catgut was left for two hours in this wash water, which was shaken occasionally. Some batches were examined in duplicate, one batch being washed by this method, while a culture was made at once of the other without washing, in order to ascertain what effect, if any, the washing process had on the catgut.

After this temporary washing to remove the adherent oil, two or three lengths of catgut (about 7 inches) were placed with sterile forceps in each of the two tubes of broth. The broth tubes were incubated for seven days at 37 C., one aerobically and the other anaerobically. By this method, two tubes were made from each suture tested.

The anaerobic condition was obtained by autoclaving the broth tubes just before inoculating and by covering the broth immediately after inoculation with sterile liquid petrolatum. Cultures of *B. tetani* from two reliable sources grew favorably under these conditions. For controls on technic pieces of ordinary coarse twine were sterilized in water and carried each day through the same processes as the specimen of catgut. The control tubes were found sterile in all tests. Further controlling tests were made by exposing tubes of broth placed in different parts of the room while the work was in progress to determine the possibility of air contamination in the working space. In one instance, one of these exposed tubes was found to be contaminated and on microscopic examination it was revealed to be a staphylococcus, an organism which was rarely found to be the one responsible for contaminated catgut. The fact that many sterile tubes of catgut, a considerable number of which had been washed in water, were found sterile, simultaneously served as a control on the wash water and broth.

PREPARATION OF MEDIUM

The medium used for these determinations was nutrient broth prepared according to the standard methods of the American Public Health Association with 0.2 per cent. of glucose added, final reaction 0.4 to 0.8 + to phenolphthalein. The broth was tubed in about 15 c.c. amounts to each tube, and then sterilized at 15 pounds pressure for 20 minutes. The glucose was added to render the medium more favorable for certain anaerobic forms.

The tubes were examined at the end of the second or third day and again at the end of the seventh day. The majority of contaminations showed up at the first reading. The physical appearance of the broth in the tubes was considered as sufficient evidence of infection. Gram stains, however, were frequently made from tubes that indicated contamination in order to determine the morphology of the infecting organism.

The catgut submitted for this examination was first prepared and completely dehydrated according to the particular process of the manufacturer. It was then immersed in the tubing fluid in the tubes—in these cases a high boiling oil—and then the tube was sealed. When sterilization by heat is employed it is necessary that all traces of moisture shall be removed or the catgut will become unserviceable when it is heated. On the other hand, the temperature to which the catgut is raised must not be carried too high or the tensile strength will be injured as a result of carbonization. Under these conditions autoclaving of dry catgut in sealed tubes is practically nothing more than sterilization by dry heat. The tendency has been, therefore, to maintain the tensile strength rather than to apply sufficient heat to kill the most resistant organisms. The experiments on the sterilization process proved conclusively that in some cases the large number of contaminations found could be attributed to inefficient sterilization.

As far as the writers know, no work has been done to determine the resistance of bacterial life to heat, when the forms of such life are completely dry, under oil, and protected from the effects of live steam.

DETERMINATION OF CRITICAL PRESSURE

A number of sterilizers were run under varying pressures to determine the critical pressure above which one could be assured of a sterile product and below which a sterile product would always be uncertain. Steam pressures varying from 22 pounds up to 32 pounds for three hours were used. It was found that with a suture which received the preliminary treatment such as those tested had received the critical pressure was between 27 and 28 pounds for three hours. Sterilizers run below 27 pounds or for a period less than three hours or by intermittent methods frequently showed contaminated catgut, and the lower the pressure the larger was the number of contaminated tubes. Twenty-five autoclaves, completely filled with tubes, were run at from 28 to 30 pounds pressure for three hours and on examination none of these tubes showed contamination. The catgut sterilized at this temperature proved to be of a satisfactory tensile strength.

EFFECT OF PRELIMINARY WASHING

During the course of the work the question was raised as to whether the preliminary washing of the catgut in the sterile water was an advantage or a disadvantage to the test. It was quite evident that when the results with the washed and unwashed catgut were compared there might be a possibility that some of the contamination had been washed from the surface of the catgut by this washing process, thereby securing a more sterile product than the actual conditions warranted. The reason for washing the gut in the beginning was that the different persons consulted all agreed that any oil which might adhere to the gut in transfer would be detrimental to any possible bacterial growth that might occur. To decide this question the samples from fifty sterilizers were run in duplicate washings, in half of which the washing process as described was used and in half the samples were planted at once without preliminary washing. The results showed about 30 per cent. more contaminated tubes from the tubes put on without washing. This result can be due to one of two causes. The washing may have reduced the amount of surface contamination on the catgut, or what appears to be more clearly the cause, the amount of catgut planted influenced the result; i. e., when the catgut was washed only two or three pieces (about 7 inches) were put in each tube; while, on the other hand, when it was put on without washing the entire coil (about 18 inches) of gut was placed in the culture tube.

A short study was made to determine whether the contamination, which was being found, was in the immersion oil or in or on the catgut itself. The oil from a series of tubes was poured off, a culture was made and the catgut was planted at the same time in correspondingly numbered tubes. The percentage of contaminations from the catgut cultures was greater than from the oil alone and in no case was evidence of contamination from the oil obtained when the corresponding catgut tube did not show similar growth.

A complete record was kept showing the size of each piece of catgut tested and the preliminary treatment that it had received. These records showed that when a sterilizer containing various sizes of catgut comes through without proper sterilization, the larger sizes of catgut will show a correspondingly increased percentage of contaminated tubes. In the same way, when chromicized and nonchromicized tubes of the same size are sterilized defectively in the same autoclave the chromicized tubes will show a larger percentage of growths. It is possible that chromicizing, like heating, renders the bacterial spores more resistant to subsequent sterilization.

CONCLUSIONS

In general it can be said:

1. When oil is used as an immersion fluid for the catgut, washing before planting should not be carried out if a fair check is desired on the sterility of the catgut. The suture should be taken from the tube for bacteriologic examination according to the methods commonly practiced among physicians when they have occasion to use catgut.
2. Chromicized catgut is slightly more resistant to sterilization by heat than the plain catgut.
3. The infection that is found is either within or on the catgut itself and is not present in the immersion oil alone.
4. From 28 to 30 pounds pressure of live steam for three hours is absolutely necessary to sterilize catgut such as that which was submitted to us.
5. Since any contamination may be pathogenic or otherwise, it seems imperative to the writers that some system of federal control should be devised similar to that for biologic products so that all firms manufacturing catgut could be required to adhere to the same standards of sterility.

Clinical Notes, Suggestions, and New Instruments

THE USE OF IODIDS IN PYELOGRAPHY

D. F. Cameron, M.D., Minneapolis

In two articles[1] appearing in The Journal of the American Medical Association about a year ago, solutions of sodium and potassium iodids were suggested as suitable opaque mediums for pyelography. In these articles, 25 per cent. aqueous solutions of these salts were recommended as best suited for pyelography. It was further stated that the sodium and potassium salts had been used interchangeably, but that the sodium salt was preferable.

A recent release from military service has enabled the author to investigate further the use of these solutions. A more complete report of this investigation will appear later, but it seems well to report now certain modifications of the conclusions reached previously.

First, it is desired to emphasize, more strongly than before, that the sodium salt is to be preferred. Second, a 17.5 per cent. solution of sodium iodid has been found to be sufficiently opaque for pyelography, and nothing is gained by using a stronger solution as was previously recommended. (Twenty gm. of sodium iodid dissolved in a sufficient amount of distilled water to make 100 c.c. makes a four-thirds molar solution, which is also approximately a 17.5 per cent. solution by weight.)

During the last two months, at the University Hospital, Minneapolis, the author has personally used, as a routine for pyelograms, solutions of sodium iodid in concentrations not exceeding 17.5 per cent. The thirteen pyelograms made have been very satisfactory. The procedure has been attended with very little discomfort to the patients and with no serious reactions whatever.

University Hospital.

PROCEEDINGS OF THE ATLANTIC CITY SESSION

MINUTES OF THE SEVENTIETH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT ATLANTIC CITY, JUNE 9-13, 1919

HOUSE OF DELEGATES

First Meeting—Monday Morning, June 9

The House of Delegates met in the Library of the Hotel Traymore, Atlantic City, N. J., and was called to order at 10 a. m. by the Speaker, Dr. Hubert Work, Pueblo, Colo.

Preliminary Report of the Committee on Credentials

The Chairman of the Committee on Credentials made a preliminary report for this committee, stating that the committee desired at this time to report progress, and that more than a quorum of delegates had qualified.

As there was no objection, the report was accepted.

Next in order was the roll call by the Secretary.

The Secretary stated that the registration of the delegates in attendance recorded the presence of more than a quorum.

A quorum being present, the Speaker announced that the House was constituted and ready for the transaction of business.

The next order of business was the presentation, correction, and adoption of the minutes of the Sixty-Ninth Annual Session.

The Secretary stated that the minutes had been printed and circulated among the members of the House of Delegates, with the request for criticisms or corrections, but none had been received.

It was moved that the reading of the minutes of the Sixty-Ninth Annual Session be dispensed with and approved as printed.

Seconded and carried.

Addresses of Executive Officers

Drs. Hubert Work, Speaker; Arthur Dean Bevan, President, and Alexander Lambert, President-Elect, addressed the house. See addendum, page 1764.

Reports of Officers

Report of the Secretary

The Secretary presented the following report, which was referred to the Reference Committee on Reports of Officers:

To the Members of the House of Delegates of the American Medical Association:

For the year 1918-19 I submit the following report:

MEMBERSHIP

The membership of the various constituent state associations which is the membership of this Association, according to records in the Secretary's office, May 1, 1919, was 82,288, as shown on the accompanying table.

FELLOWSHIP*

The Fellowship of the American Medical Association on May 1, 1918, was 44,715. During the year 753 Fellows have died, 2,193 have resigned, 310 have been dropped as not eligible, 257 have been dropped for nonpayment of dues, and 28 have been removed from the rolls on account of being reported "not found," making a total of 3,541 names to be deducted from the Fellowship roll. There have been added 4,238 names to the Fellowship roll of which 2,305 were transferred from the subscription list. The Fellowship of this Association on May 1, 1919, was 45,412, a net increase for the year of 697.

This gain in the number of Fellows, as in previous years, is due largely to circularizing subscribers to THE JOURNAL who were eligible, urging them to become Fellows.

INTERIM APPOINTMENTS

During the year, Dr. Ludvig Hektoen, Chicago, tendered his resignation as a member of the Council on Health and Public Instruction, and the President appointed Dr. Victor C. Vaughan, Ann Arbor, Mich., to serve on this Council until this annual session.

Dr. H. Gideon Wells, Chicago, tendered his resignation from the Council on Medical Education, and the President appointed John B. Dodson, Chicago, to fill the vacancy until this annual session. Dr. H. D. Arnold, Boston, also resigned from the Council on Medical Education, and the President appointed Dr. Isadore Dyer, New Orleans, to fill this vacancy until this annual session.

THE AMERICAN MEDICAL ASSOCIATION AND THE RECONSTRUCTION PERIOD

At its annual sessions during the progress of the war, reports have been submitted to the House of Delegates regarding the Association's cooperation with the Federal Government in matters involving the services of physicians. These reports show that the Association endeavored to assist the Government in every way in which this could be done by a civilian organization. A review of these war activities would reveal few, if any, instances where the Association could have done more or acted differently than it did. However, in mobilizing an armed force under the conditions which existed, there were many occasions for criticism certain of which may appear to be warranted from the view point of the individual. The House of Delegates should know that letters from physicians have been received at the Association Headquarters in which the writer complained of the conditions of service in which he found himself, or criticised the Association's war policy. For example, physicians who were called to active military service and held in training camps complained because they were not assigned to posts in connection with the armed forces. Since the cessation of hostilities, letters have been received from physicians who have not been sent overseas, urging that the group to which they belong should be the first to be demobilized. On the other hand, physicians on overseas duty argued that because they have been kept away from home for a considerable period of time, they should be given the preference by being returned promptly to civil practice. Manifestly these matters are not within the province of this Association. Since the Armistice, a considerable number of physicians have been released from military service, and presumably the demobilization may be expected to proceed more rapidly as the overseas forces under arms are returned and discharged, but a sufficient personnel of the Medical Corps must be retained in service until the army has been reduced to a peace status.

Reports regarding the return of physicians to civil practice received from the different state associations are gratifying; it is almost the universal comment that these physicians are finding a hearty reception in the localities where they formerly practiced. When these physicians locate in new communities, they are in practically all instances welcomed by the medical profession of the locality. The state associations and the county societies undoubtedly will find a field for effective service in assisting these returning physicians to reestablish themselves in civilian practice. Moreover through our organization the courtesies which have always been shown by one physician to another may overcome the unavoidable irritations which arise between physicians who have served in the Army, the Navy and the Public Health Service and those who have remained at home.

---

* These figures do not include those who are now Fellows by virtue of their being commissioned and on active duty as Medical Reserve Corps Officers but who previously have not been Fellows.

It cannot be expected that an exact prewar status ever will be restored. The task which confronts the American Medical Association, with its constituent state associations and component county societies, is to assist in bringing about a better state of affairs in the medical profession.

SECTS IN MEDICINE

The Principles of Ethics of the American Medical Association declare that "A physician should not base his practice on an exclusive dogma or sectarian system, for sects are implacable despots; to accept their thralldom is to take away all liberty from one's actions and thought." In a word, for years the American Medical Association has welcomed to its membership those who are primarily physicians. The several military services have commissioned physicians without regard to the fact that a considerable number of them have graduated from so-called sectarian schools. These qualified as physicians. All commissioned medical officers served under similar conditions and used in their professional work the same standard equipment. Sectarianism found no place in the medical military service. War experience has confirmed the position which the American Medical Association has maintained for so long a time and the Association may have a proper pride in emphasizing that it is a non-sectarian, all-inclusive organization of physicians.

Commissioned Officers[5] and Honorary Fellows								2,369	
								45,412	

* Not including Fellows of American Medical Association.

Note.—The number of members of the different associations stated in this table is in accord with the membership of the several associations as they were reported to the Secretary on May 1, 1919.

The lack of an effective uniform system for reporting the membership of the state associations accounts for whatever discrepancies this table shows and detracts from the value of the statement.

Component societies are those societies which compose the state association. A component society may include one county or more.

[1] The state of Maryland has 23 counties and the city of Baltimore; Missouri has 114 counties and the city of St. Louis.

[2] These state associations are divided into district societies, and these are listed in the table as component societies. Some of these districts are smaller and some larger than the county, the county lines being ignored.

[3] Provision is made for the physicians in each of these counties to join the component society in an adjoining county.

[4] Virginia has recently adopted the plan of organization and is now establishing component county medical societies.

[5] This figure includes the Medical Corps of the Army, the Navy and the Public Health Service.

ELECTION OF HONORARY FELLOWS

The By-laws, Section 5, Chapter IV, reads: "Not more than three honorary Fellows shall be elected in any one year." Under ordinary conditions, this is a wise provision. However, this Victory Meeting is an occasion when the House should be in position to elect more than three Honorary Fellows. To present this matter in a practical form for the consideration of the House, it is proposed that the By-law quoted be amended so as to read:

> Not more than three Honorary Fellows shall be elected at any annual session; *provided, however, that on recommendation of the Council on Scientific Assembly, and by unanimous vote the House may elect more than three Honorary Fellows.*

FELLOWSHIP DESIGNATION

It has been suggested that Fellows of the Scientific Assembly of the Association be permitted to use an authorized designation after their names in signing scientific papers or under other conditions where it is desirable to indicate their Fellowship. The following designations have been proposed: F. S. A.—Fellow Scientific Assembly; F. A. M. A.—Fellow American Medical Association; F. S. A. A. M. A.—Fellow Scientific Assembly of the American Medical Association. It would seem advisable that the symbol, if one is adopted, shall recognize that Fellowship is a relationship to the Scientific Assembly—the scientific convention held in connection with the annual session of the Association.

Other matters in which the office of the Secretary of the Association has been concerned are reported to the House of Delegates from other sources.

Respectfully submitted,
ALEXANDER R. CRAIG,
Secretary.

Report of the Board of Trustees

Dr. Thomas McDavitt, Chairman, presented the following report, which was referred to the Reference Committee on Reports of Officers.

To the Members of the House of Delegates of the American Medical Association:

Two years ago the Board of Trustees presented to you a rather pessimistic outlook as regards THE JOURNAL. It was predicted that physicians entering the Government service would not keep up their subscriptions, and that quite a falling off in the subscription list might be expected. These predictions were not verified, as will be seen by the tables giving the circulation, published in the addenda to this report. It is true that a large number of physicians discontinued their subscriptions to THE JOURNAL on entering the service, but later, when they were able to give a definite address, many ordered their copies to be forwarded. Special efforts were made to accommodate medical officers not only by changing addresses as needed, but in every other way possible. THE JOURNAL records show that the actual number of changes of address for men in the Army during the year was 22,286.

The increase in subscriptions for the year 1918 was small —229 all told—but under the circumstances, this must be regarded as satisfactory. Although this report covers the

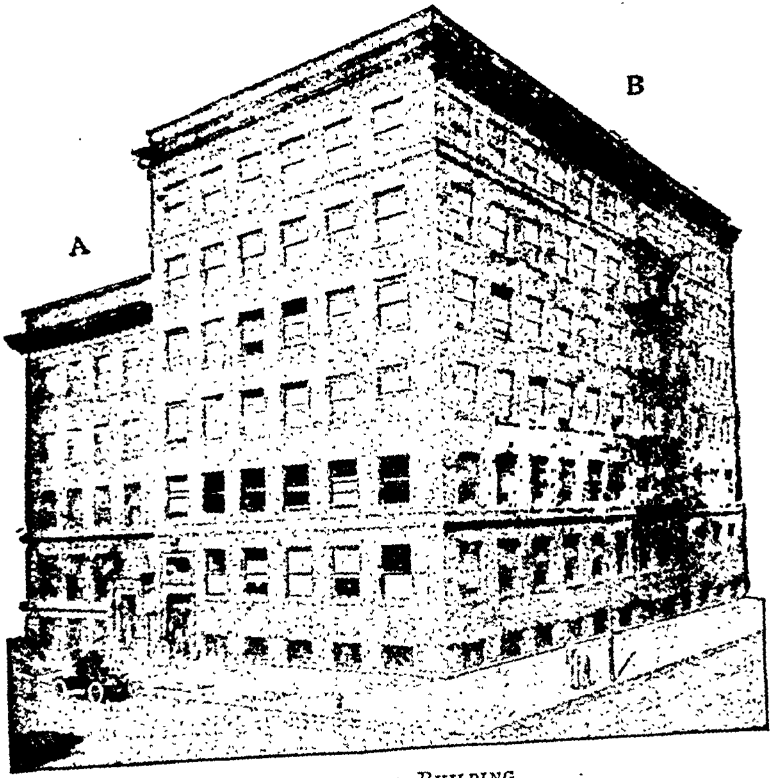
Disposition of Lawsuits

Last year the Board presented a statement regarding the disposition of five lawsuits during the year 1917, each claiming damage to the amount of $100,000, and in addition the Lydston suit attacking the constitutional rights of the Association to meet and transact business outside the State of Illinois. During 1918 three more suits have been disposed of:

> The Jenner Medical College vs. the Association and the Council on Medical Education, for half a million dollars. Many alleged grounds of libel were set forth. This case, which has been pending for six years, was dismissed on March 6.
>
> Two cases of E. Wells Kellogg and Edward Patrick Cooke, each for $100,000, for libel, based on an article published in The Journal exposing the Friedmann consumption cure, with which their names were connected. Both were dismissed in April.

Buildings

The Association's increased activities are beginning to crowd the headquarters, especially in the printing department. The Board has under consideration the proposition of tearing down the old building and extending the main building to take in this space. If this were done we would have a steel and concrete structure, 100 by 120 feet, six stories and basement. The building now occupied by the Association is constructed to carry two, or even four, more stories; but it probably is not expedient to make more than a six-story building at the present time.



Association Building

The proposition under consideration is to tear down the small building on the left and replace it with a steel and concrete building corresponding to, and thus completing, the main structure. The smaller building is what is called mill construction and is not fireproof.

As will be noticed in the Auditor's Report, the real estate of the Association is listed as worth $231,463.59. It consists of three lots, each 40 by 100, located at Grand Avenue and North Dearborn Street. Two of these — the corner and the one next to it — were purchased in 1902 for $42,646.90; the third, in May, 1903, for $14,950.15. Thus the lots cost $57,596. The first building was completed in November, 1902, at a cost of $41,322.90. An additional story was added in 1905, and the building extended back 50 feet to take in the new lot, at a cost of $23,622.47. Thus the old building (A) cost $64,945.37. Each year a depreciation is allowed on this building, and it is now carried on our books at $14,379.93. Building B was erected in 1911 at a cost of $202,189.95. The annual depreciation has brought this down on our books to $159,479.66. Thus, while the real estate—land and buildings—actually cost $324,731.37, they are in the Auditor's Report at only $231,463.59.

War Service

As the War Committee is making a report, it is unnecessary for us to go into details. Suffice to say that the expense connected with the War Committee, the Selective Service, and the work done in cooperation with the Surgeon-General amounts to approximately $17,000. This covers the whole period of the war — 1917 and 1918.

Investigation and Standardization of Hospitals

One important work is that connected with the investigation and standardization of hospitals. This work may be regarded as having been begun in 1906, for at that time the first attempt was made to obtain a list of dependable hospitals in the various states. The work has been developing since that time, and an abundance of accurate data has been collected in regard to the number and character of hospitals, their bed capacity and the physicians on the attending staffs. The efforts toward standardizing the hospitals, especially those providing internships for medical graduates, is being energetically pressed, and in this movement the abundance of data collected will be of service. This work is described in detail in the report of the Council on Medical Education, it is mentioned here to emphasize its importance.

In the form of an addendum we give details regarding the circulation of The Journal; also details covering the finances of the Association, these being included in the Treasurer's and in the Auditor's report.

Respectfully submitted,

Frank Billings.

January 1st, 1910	33,032	19,832
January 1st, 1911	33,540	20,504
January 1st, 1912	33,250	21,620
January 1st, 1913	36,082	19,863
January 1st, 1914	39,518	19,751
January 1st, 1915	41,254	20,430
January 1st, 1916	41,938	22,921
January 1st, 1917	42,744	22,156
January 1st, 1918	43,420	23,117
January 1st, 1919	42,366	24,687

During 1918 there were transferred to Fellowship 2,522 names from the Subscription Department, and fifty-nine from the Archives of Internal Medicine and the American Journal of Diseases of Children—a total of 2,581; 588 Fellows were discontinued as such, but were continued as subscribers.

Treasurer's Report

Report of the Treasurer of the American Medical Association for the year ended December 31, 1918.

ASSOCIATION RESERVE FUND

Reserve Fund as at December 31, 1917		$166,236.27
Investments		35,000.00
Interest—Bonds	$7,197.45	
Interest—Uninvested	293.66	
		7,491.11
Reserve Fund as at Dec. 31, 1918		$208,727.38

TREASURER'S GENERAL ACCOUNT

Balance as at Dec. 31, 1917	$ 256.62
Interest on Bank Balance	8.72
Balance as at Dec. 31, 1918	$ 265.34

DAVIS MEMORIAL FUND

Balance as at Dec. 31, 1917	$ 3,544.69
Interest received for the year	107.11
Balance as at Dec. 31, 1918	$ 3,651.80

Auditors' Report

Chicago, January 23, 1919.

To the Board of Trustees,
American Medical Association, Chicago, Illinois.
Dear Sirs:

In accordance with your instructions, we have audited the accounts of the American Medical Association for the year ended December 31, 1918, and now submit our report thereon.

SURPLUS ACCOUNT

The surplus at the beginning of the year amounted to $423,433.87, and the surplus at the end of the year amounted to $471,661.50, an increase of $48,227.63, which may be accounted for as follows:

Net Gain on Operations	$ 83,227.63
Less Transfer to Reserve Fund	35,000.00
Net Increase in Surplus	$ 48.227.63

The net increase in surplus is spread over the assets and liabilities as follows:

Increase in Assets:		
Current and Working Assets		$ 52,409.87
Prepaid Expenses		1,374.01
		$ 53,783.88
Less Decrease in Property and Equipment		4,595.87
		$ 49,188.01
Less Increase in Liabilities:		
Advance Payments on Publications	$ 2,092.81	
Less Decrease in Accounts Payable	1,132.43	
		960.38
Net Increase in Surplus, as above		$ 48,227.63

FINANCIAL POSITION

The financial position of the Association as at December 31, 1918, is shown in the following statement:

Balance Sheet as at Dec. 31, 1918

existence, but also for the formulation of plans for the future.

The Council on Health and Public Instruction was organized at St. Louis in 1910. During the reorganization period of the Association from 1902-1910, many independent committees had been created, dealing with closely related subjects but without any coordination or definite division of functions or jurisdiction. At the 1909 session, the section on hygiene and sanitary science asked the House of Delegates to create a permanent council on these subjects. The Reference Committee, to which this request was referred, called attention to the close relation existing between public education, medical and public health legislation and the development of hygiene and sanitation and recommended the appointment of a committee to consider the advisability of combining the functions of legislation, public instruction, organization and public sanitation in a permanent council. This committee was appointed and reported the following year, recommending the establishment of such a permanent council. The Council on Health and Public Instruction was accordingly created and appointed in June, 1910, and held its first meeting and organized in July of the same year. In it were merged the old committees on Medical Legislation, Public Instruction on Medical Subjects, Defense of Medical Research, Organization, Uniform Regulation of Membership, Visual Standards of Pilots, Public Health Education, Prevention of Blindness and Postgraduate Study. In 1911, the work of the Council consisted of the promotion of the work of Dr. J. N. McCormack, at that time engaged in organization work for the Association; in the development of a series of fifteen pamphlets on the Defense of Medical Research, which, in additon to thirteen already published, formed a standard series of twenty-eight monographs on this subject; in the development of a bureau on medical legislation by which it was hoped some of the problems in this field could be solved and in studying the problem of public education by state boards and other agencies through popular pamphlets.

The next session, in 1912, the Council reported that a Press Bureau had been organized and conducted during the past year, by which regular press bulletins had been sent to approximately 5,000 daily newspapers each week, the Speakers' Bureau had been organized and in the three months of its existence had supplied speakers for forty-four meetings; nine pamphlets on various public health subjects had been prepared, printed and distributed; a Handbook for Speakers on Public Health had been compiled, printed and distributed to the speakers of the Bureau. The Council also reported the organization, through cooperation with the National Electric Light Association and the American Institute of Electrical Engineers, of the Committee on Resuscitation after Electrical Shock; of the appointment, in cooperation with the National Education Association, of a Joint Committee on Health Problems in Education; of a Joint Committee on Medical Expert Testimony, consisting of representatives of the American Medical Association, the American Bar Association, the Commissioners on Uniform Laws; of a Committee on Rural Sanitation consisting of representatives of the American Medical Association, the Association of Railway Surgeons and the Conference of State and Provincial Boards of Health; of a Committee on Vital Statistic Legislation consisting of representatives of the American Medical Association, the American Public Health Association, the American Bar Association, Commissioners on Uniform Laws and the Bureau of the Census. In addition the Council had done much work along legislative lines and had represented the Association in a campaign for the establishment of a national department of health.

In 1913, the Council reported the continuation of these activities, showing that speakers had been furnished for 213 meetings during the year; that fourteen pamphlets had been prepared and distributed and that the various subcommittees of the Council had been functioning successfully during the year. A Committee on Resuscitation from Mine Gases, as the successor of the Committee on Resuscitation after Electrical Shock, had been created at the request of the Federal Bureau of Mines. These two committees had standardized the methods of artificial respiration and the treatment of the drowned and those suffering from gas, electric shock, etc.

In 1914, after four years of existence, the Council presented to the House of Delegates a definite program, in which it endeavored to formulate the duties and activities of the organized medical profession in the public health field. In outlining such a program, the Council assumed that the primary object of its existence was to place before the profession and the public of the United States the objects, purposes and work of the organized medical profession as represented by the American Medical Association and its constituent state and component county societies, so as to secure public support and endorsement of our efforts for the improvement of public health conditions in the United States. Three general lines of action were accordingly recommended. These were:

1. A thorough investigation of present public health conditions in the United States with the view to securing more accurate information on all phases of the public health problem than is now available.

2. Education of the public by every possible means in order that the people may understand the enormous advances in scientific medical knowledge during the last generation and the possibilities of utilizing such knowledge in the prevention of disease, the reduction of the death rate and the prolongation of human life.

3. The crystallizing of such educated sentiment in necessary public health laws which will render possible the conservation of human life commensurate with our advancing knowledge and will render such laws effective through the only force available in this country, namely, educated and enlightened public opinion.

Under the first head, namely, the investigation of the present public health situation, need for additional knowledge was subdivided into four classes, namely: (*a*) public health activities of the federal government; (*b*) state public health activities; (*c*) municipal health organization; (*d*) voluntary public health organization.

Under the second head, the education of the public, the Council reported the continuation of the Press Bureau, forty-two bulletins having been sent to 4,900 newspapers at a total cost of approximately $2,300. The Speakers' Bureau had been maintained during the year, speakers had been furnished for 133 meetings at a total cost of approximately $1,900, and a standard set of public health pamphlets had been prepared and published for the use of state boards. In addition a series of twenty pamphlets on Conservation of Vision had been prepared and issued by the subcommittee on this subject. This set of pamphlets has remained in use ever since and has been recognized as a standard in this field. A series of six pamphlets on cancer and its prevention had also been prepared and published. The total number of pamphlets issued during the year was 57,250.

In 1915, the Council reported the continuation of its program, particularly the carrying on of a comparative study of state public health activities by Dr. Charles V. Chapin, health commissioner of Providence, Rhode Island, as the special representative of the Council. Dr. Chapin's report was the first effort to collect data on state health activities with a view to the ultimate standardization and classification of state public health work. Regarding voluntary public health activities, the Council endeavored through a conference of representatives of the various voluntary organizations held in New York on March 13, 1915, to coordinate the numerous organizations in this field.. Along educational lines, the Council reported that, at the direction of the general manager, the mailing list of the Press Bulletin had been reduced to 2,200. Owing to the limited appropriation the amount available for the Speakers' Bureau had been limited to $1,000. For this amount speakers had been furnished for 151 meetings, an average expense of $9.80 a meeting. During the year 285,400 pamphlets have been printed and distributed.

In 1916, the Council reported further development of its program including the publication of Dr. Chapin's Report on State Public Health Work, with a rating sheet of the forty-eight state health organizations showing their comparative standing in different lines of state public health work, their appropriations, expenditures, etc. A preliminary edition of 1,000 copies of this report was distributed to members of state boards of health and officers of the Association for criticism and suggestions and the Council expressed the hope that at the end of two or three years a second survey might be made for confirmatory and comparative purposes. Owing to reduced appropriations, the Press Bulletin had been suspended, and the plan of the Speakers' Bureau had been modified by asking local organizations to pay the expenses of speakers instead of having these expenses borne by the Association. During the year, 1,133,500 pamphlets had been printed and distributed. Cooperative work had been carried on through the Elizabeth McCormick Memorial Fund and the dry-goods stores of the country for child welfare.

Before the next meeting of the Association, the United States had entered the world war. The New York meeting found all of the members of the Association largely absorbed in the war activities of the nation and the profession. The 1918 meeting showed a large proportion of the officers and members of the Association in uniform and in some field of active service. This condition continued up to November, 1918, and has been more or less true during the entire year, the medical officers being discharged slowly and returning to their civil activities. At the time of writing (April 23, 1919) there are still nearly 20,000 medical officers in the service. It will probably be the middle of summer or the early fall of 1919 before the medical profession is demobilized.

It becomes necessary, therefore, in planning for the reconstruction of the activities of the Council to reconsider the plans previously proposed and endorsed by the House of Delegates at successive sessions and to discuss them in the light of the actual accomplishments of the Council and its subcommittees. Regarding the general plan of public education carried on for a number of years through press bulletins, Speakers' Bureau, public meetings, distribution of pamphlets, leaflets, etc., these methods, while largely new at the time they were inaugurated, have been taken up by other organizations. It has been the policy of the Council not to undertake work that was being done by other organizations nor to attempt to compete with other organizations carrying on public health work, the desire of the Council being to inaugurate work that could not well be undertaken by other bodies and to coordinate existing organizations by drawing them together for a common purpose rather than to create or perpetuate any rivalry between existing organizations. It seems evident that the propaganda period in public health work is past. Many of our national health organizations, either special or general, as well as many of our state boards of health are now sending out press bulletins and much suitable health material is now being supplied to newspapers. It is, therefore, doubtful whether anything would be gained by the reestablishment of the Press Bureau. In fact, it seems highly probable that the continuation of this work can be safely left to special organizations.

The same thing is true regarding the Speakers Bureau. A large number of organizations, either local, state or national, have followed the lead of the American Medical Association in this particular in the last five years. It is especially doubtful whether with the limited resources of the Council it would be advisable to attempt the financing of speakers' expenses. As frequent requests for accredited speakers on public health topics continue to come to the Association headquarters, however, it would be advisable to prepare and maintain a list of representative physicians, members of the Association and recognized authorities on some phase of public health work who are willing to give public addresses on various occasions. In the great majority of cases, the local committees of organizations desiring speakers are perfectly willing to pay the necessary expenses of the speaker so that no appropriations for this purpose would be required. It is desirable, however, to prepare and issue each year a carefully selected list of speakers who are willing to fill a limited number of engagements and to distribute this list to women's clubs, local health organizations and other bodies desiring to secure speakers on some public health topic.

Regarding the distribution of pamphlets, this department of the Council's work, as shown by the summary included herein, has practically become self-supporting. By making a nominal charge for these pamphlets, especially when supplied in quantities, the money thus secured can be used over and over for printing educational material. Having once been prepared and stereotyped, the cost of printing involves only the cost of paper, ink, press work and labor. The complete list of pamphlets appended shows the scope of this line of work. This list can be with advantage considerably increased by the preparation of such pamphlets as are needed for the better education of the profession and the public. Several new pamphlets are now under consideration.

The increasing number of organizations interested in public health work accentuates the fact brought out by Pres. George E. Vincent of the Rockefeller Institute in his address before the American Public Health Association in December, 1918, that one of the most important needs in the public health field today is that of increased knowledge of public health conditions. Our knowledge even on fundamental health questions is fragmentary and in many cases based on insufficient foundation. Public health leaders are coming to recognize that improved conditions in the public health field cannot be brought about wholly by legislative enactment; that restrictive laws have only a limited value; and that the more accurate and complete our knowledge, the better can health conditions be controlled and improved through public sentiment rather than through restrictive legislation. Especially is it of the utmost importance that the American Medical Association, as the recognized official body of the American medical profession, should have clearly defined objects and purposes and should know definitely and accurately just what it is trying to accomplish and along what line its energies are to be exerted. Of the four general subdivisions found in the program of the Council as outlined in 1914, none of them has as yet been carefully or exhaustively studied. The fourth class, namely, voluntary public health organizations, is in practically the same condition as five years ago in spite of constant efforts to secure better coordination and cooperation. The American Public Health Association has recently taken up this question and has organized a Council composed of representatives of a number of the fifty-seven different national public health organizations in existence with a view to securing some kind of harmony and cooperation in this field. The creation of unnecessary organizations cannot well go much farther. The probable outcome will be the absorption of a large number of organizations by some single comprehensive body in the next few years. Whether this will come about by the occupation of this field by the American National Red Cross following its reorganization after the war or by the organization of some new general public health organization along popular lines remains to be seen. It is extremely doubtful, however, whether the Council or the American Medical Association can at present do very much to clarify this situation. It is also doubtful whether the purely educational activities of the Council can at present be enlarged to any great extent with any degree of success. There remains, therefore, one field in which the Council and the Association are preeminently fitted to exert themselves, namely, the increase of knowledge regarding organized public health activities.

In its report for 1914, the Council said, regarding the need of a careful study of the public health work of the federal government with a view to determining exactly what the federal government is doing and can do for public health: "The need for such an investigation hardly needs more than to be stated. The American Medical Association stands unreservedlly pledged to the securing at the earliest possible moment of an adequate national health organization. In the discussion of this subject . . . a lack of accurate and complete information regarding present health activities on the part of the federal government has been apparent. Extreme claims have been made on both sides, one set of advocates asserting that the United States government was doing more for public health than any other national government in the world, the other asserting that practically nothing was being done by our government which could compare with the health activities of European nations. Such a condition is not credible to a scientific organization."

This statement is as true today as it was five years ago. In addition, no careful study has ever been made, from a legal standpoint, of the exact limitations of the federal government along public health lines. What can the national government do under the constitution for public health? No one is today in a position to answer this question authoritatively. As a result, bills are drafted and measures proposed that would probably, if adopted, be unconstitutional, while such measures as the Harrison Narcotic Law, a law intended solely for the improvement of public health conditions in a broader sense, are passed ostensibly as revenue measures and are later by amendment converted into revenue producing measures with serious injustice and inconvenience to law-abiding physicians. If Congress has the power to regulate the sale of habit-forming drugs for the public good, then it is not necessary for Congress to pass such measures under the guise of revenue laws which after their passage are distorted and misconstrued by federal officials into unfair and inequitable revenue producing measures. This country will never have a federal department of public health such as has been advocated rather vaguely for fifty years past and such as is now being strongly advocated in England, Canada, Australia and other nations until the public health functions and powers of the federal government under the constitution have been definitely determined. Two questions must be answered: First, what can the federal government do for public health; and second, what is the federal government now doing for public health. These questions are not at present being considered by any other organization, yet their solution is fundamental to the development of public health in this country. They are problems to which the American Medical Association can fittingly and properly direct its attention. Having secured some authoritative information on these two questions, we will then be able to put the influence of the American Medical Association behind an intelligent movement for a national health organization. Correspondence has already been inaugurated with officials and influential members of the American Bar Association, looking toward the creation of a joint committee on the Constitutional Limitations of Federal Public Health Work.

Regarding the second field for investigation, that of state public health activities, the report of the Council in 1914 said, "There is today in every state in the Union some form of public health organization. Owing to our form of government, each of these organizations is working independently. As the reports of the various state boards are not made on a uniform basis, a comparison of their various activities and a tabulation of the results secured by their efforts are difficult. It is, therefore, practically impossible today to summarize the public health work which is being done by the different state boards of health, to compare one with another or to establish any standards by which their relative merits may be determined. The first necessity for such a comparative study is clearly a collection of authoritative official data on the subject." The report of Dr. Chapin, published by the Council and distributed two years later, is the only effort that has been made to obtain a comprehensive view of this field. The large number of requests that have been received for the limited edition of this report shows the value of such a study. The great majority of state board members and secretaries accepted this report for what it was intended to be, namely, an effort to secure, digest and tabulate authoritative, official information regarding state board of health activities with a view to showing the relative strength and weakness of public health work in each state, and thereby aiding the state health boards and secretaries in securing better laws and larger appropriations. It was not intended in any sense as a criticism of existing boards or of public health officials. In fact, in many cases it showed clearly that excellent results had been secured by state board secretaries under difficult conditions with small appropriations and limited powers. In a few instances, the statements made in the report or the conclusions drawn by Dr. Chapin were resented by sensitive state officials, in spite of the definite statement in the introduction that the object of the publication was not in any sense due to a desire to be either critical or dictatorial, but rather to present in tabulated form the essential facts regarding state public health work; in the hope that this material would be of service to state boards of health and executive secretaries in presenting to governors, legislators and executive committees a clear statement of the facts regarding public health work in each state, in order that the rating sheet might be of value in pointing out the weak points in each state by the strengthening of which the relative standing of the state in the public health field might be raised. The criticism and opposition encountered was of exactly the same character as that shown in the first years of the work of the Council on Medical Education by medical colleges found to be deficient in equipment, personnel or administration. This is to be expected in any such work and the arousing of such criticism is only an evidence of the value and necessity of the survey. With increasing interest in public health in all its phases, the increasing demands on state health organizations by the public and the enormously increasing opportunities for service that have developed during the past five years, it is more than ever desirable that this field should be more carefully, critically and persistently studied and discussed than has been the case heretofore. Here again no other organization has shown any disposition to take up this line of work. The federal government obviously will not undertake it and it is not desirable that it should since any investigation that it might carry on would necessarily be of an official character. Here again the parallelism with the work of the Council on Medical Education is apparent. The reason why the classification and standardization of medical colleges by the Council on Medical Education has been so brilliantly successful is that the Council had no legal standing or authority of any kind and assumed no such authority, restricting its efforts to collecting, tabulating and publishing the facts regarding medical colleges, leaving to public opinion, both in the profession and among the laity, the task of enforcing the findings of the Council.

In the third field of health activity, namely, municipal health organization, a still greater need for careful study exists. While there are only forty-eight states, each differing as to size, population, physical characteristics, material resources, industrial conditions and public health needs, there are 325 cities of over 25,000 with all possible varieties of health organization. Yet there is no basis of comparison by which it can be determined what form of health organization is best adapted for a city of 25,000, 50,000 or 100,000; how the health organization and the administration in one city compares with another; what the legitimate expense of proper health administration in a city of a certain size should be; what the functions properly undertaken by a city health department should be or how these should be related to a state health organization; or whether or not the people of any city are receiving an adequate return for the amount of money paid out for health purposes. For the city that desires to improve its health organization or to establish one de novo, there is no information as to what kind of health organization such a city should have; what should be its personnel or equipment; how much money should be appropriated; or what duties or activities should be imposed on it. An effort has been made by the American Public Health Association in the last few years to discuss this question and to formulate some general principles. No comprehensive study of the question, however, has as yet been made. The plans of the Council provide for a comparative study of the health organization and activities of our various cities in the hope of being able to establish standards for such work for groups of cities of different sizes, to compare the public health work done in our leading cities and by such standardization and comparison to stimulate and encourage better health organization in our American municipalities.

Another task taken up by the Council was a study of the legal relations and responsibilities of physicians and the legal aspects of public health. This field, for obvious reasons, has never been carefully studied either by physicians or lawyers. It offers no prospect of financial reward to lawyers and it is only of interest to physicians so far as their personal interests are involved in some specific case. The Secretary has for many years collected a large amount of material on this subject. One volume of a proposed four-volume set was issued in 1915, namely, "Digest of Supreme Court Decisions on Medical Practice Acts," in which were indexed 752 court decisions on this subject, 396 of which were abstracted. Work was begun and nearly completed on the second volume, "A Digest on the Medicolegal Relations of Physicians," for which approximately 1,800 supreme court decisions were collected and abstracted. This work can probably be completed and prepared for publication in a few months. In the field of malpractice, there are probably 1,500 cases on record which have gone to courts of last resort for opinions, while on the fourth subject, "The Powers and Duties of State Boards of Health," there are approximately 800 decisions on record. This work should be completed and published, as it comprises material that is not available in any other form nor through any other agency.

Summing up the program of the Council submitted to and approved by the House of Delegates in previous reports and eliminating those activities that have been taken over by other agencies or that time and experience have shown not to be desirable of development, we find that there remains the following work definitely belonging to the Council:

1. The routine work of the Secretary's office, consisting of the preparation, printing and distribution through all available channels, of public health educational literature, of the coordinating, so far as possible, of other public health organizations through interlocking committees; of the representing of the American Medical Association in the public health field and in various conventions, conferences and meetings; of the carrying on of the routine correspondence of the Council, including the furnishing of information on all available public health topics to physicians and laymen interested; and of the maintenance and distribution of a speakers' list, from which can be secured speakers of professional standing for public occasions of all kinds.

2. The completion of the medicolegal work begun, involving the publication, first of the "Digest of Supreme Court Decisions on the Medicolegal Relations of Physicians"; second, of the "Digest on Powers and Duties of State Boards of Health"; and third, of the "Digest on Professional Responsibility and Malpractice."

3. A study of (*a*) federal public health activities and limitations, (*b*) state public health activities and organizations, (*c*) municipal health organizations, with a view to presenting to the public and the profession the facts regarding existing conditions and the lines in which practical and feasible reforms and advances in this field can be carried out and the use of the influence of the Association and profession to secure such reforms.

The development of this program will necessarily be limited to the Council's resources, which again will be dependent on the appropriations made for this purpose by the Board of Trustees, which in turn will be necessarily limited to the financial resources of the Association. It will probably be necessary for the Council to take up these different lines of work successively rather than simultaneously and to undertake one thing at a time, completing that work before another line of activity is undertaken. The program outlined above, therefore, will probably involve a number of years. It is submitted herewith to the House of Delegates as a tentative program for criticism, modification or approval as the House of Delegates may see fit.

INCREASED TAXATION UNDER THE HARRISON LAW

During the past year the registration tax for physicians under the Harrison Law has been increased from $1 to $3. You are all familiar with the history of the passage of this law. Enacted by Congress to carry out our international obligations in compliance with the recommendations of the Shanghai Commission on the Control of the Opium Traffic, it was put in the form of a revenue measure simply to give Congress jurisdiction. THE JOURNAL and the American Medical Association cooperated heartily and cheerfully in securing the passage of this measure. The medical profession of the country as a class accepted the imposition of a nominal registration tax and the inconveniences connected with the operation of the law as necessary accompaniments of any practical plan for the control of illegitimate traffic in habit-forming drugs. In the revenue bill for 1918, however, a new tax schedule was provided increasing the tax on physicians from $1 to $3. This is simply an effort on the part of the Department of Internal Revenue to make a revenue-producing measure out of what was originally and legitimately intended for a restrictive law for the public good. The law will not be any more effective in its operation under a $3 tax than it was under a $1 tax while it will impose an additional burden of about $300,000 on physicians. The only justification of the law is the public good. The expenses of its administration should be paid out of the public funds and not out of a special tax levied on one particular class. While the increase in the amount of the tax might be justified as a war measure, now that the war is over there is no possible justification for it. The Council, therefore, recommends that the House of Delegates record its emphatic disapproval of this unjustifiable attempt to exploit physicians and that it demand the reduction of the registration fee for physicians to a nominal amount.

VITAL STATISTIC LEGISLATION

Probably the most successful, in fact the only successful, effort that the American Medical Association has made in late years to influence legislation is now happily nearing completion. Although the Association very early in its history recommended the passage of suitable laws in the different states for the registration of births and deaths, nothing effective was done on this subject until 1906. At that time the registration area for deaths established by the Federal Bureau of the Census consisted of only ten states, namely, New England, comprising Maine, Vermont, New Hampshire, Massachusetts, Rhode Island and Connecticut, and New York and New Jersey in the east with Michigan and Indiana the only other states represented. The difficulty had been that legislation on this subject had been left entirely to state initiative and any laws that might be adopted by the different states were so divergent in principles and details as to make any adequate compilation of birth and death reports for the different states impossible. Dr. Cressy L. Wilbur, at that time chief statistician of the Division of Vital Statistics of the Bureau of the Census, had become thoroughly discouraged and was about ready to give up any further efforts for better conditions. Yet the importance of vital statistics legislation as underlying any adequate and efficient state health organization was apparent. It seemed evident that the passage of a model standard law on this subject by each state was absolutely fundamental to public health progress. Accordingly this matter was taken up by the Committee on Medical Legislation, one of the forerunners of the present Council. The newly adopted Pennsylvania law which had been very carefully drafted was taken as a model. A Joint Committee was organized through cooperation with the American Public Health Association and a model bill was drafted, this being one of the few subjects on which it is possible to draft a standard bill suitable for adoption by every state. Endorsement of the model bill was then secured from the American Medical Association, the Federal Census Bureau, the American Public Health Association, the American Statistical Association, the American Bar Association, the American Federation of Labor, the National Conservation Congress, the General Federation of Women's Clubs and other national organizations interested. A plan was adopted involving the selection of not more than two or three states each year, the education and stimulation of public opinion by the distribution of pamphlets, editorials and other material for a year or more previous to the introduction of the bill, the arousing and coordinating of all the organizations and interests in the state and in general the creation of a real public sentiment in favor of suitable legislation.

information in regard to standards of medical education and licensure.

(*d*) Prior to 1909, detailed information in regard to medical students was not obtained until the year they came up for graduation. The Council was then impressed with the importance of securing the necessary detailed information at the time the student matriculated. A Medical Students' Register has been maintained since 1910 and in this work the Council has had the most gratifying cooperation on the part of deans of medical colleges. The information obtained includes a report of all new students admitted each year and a report from each individual student giving the date of birth and a complete educational history. The information is kept on cards and as soon as the student has graduated and obtained his license this card is transferred to the biographical index and the data regarding the graduate is included in the next edition of the American Medical Directory.

II. Annual Conferences

What was probably the most effective procedure in the Council's work was the Annual Conference on Medical Education and Licensure which has been held every year since 1904 when the Council was created. Through this conference the Council secured the advice and cooperation of university presidents, medical educators, members of state licensing boards and other interested individuals by means of which standards of medical education and licensure, after careful discussion, were generally adopted. These conferences have grown from the standpoint of both attendance and influence. Since 1911 the two confederations of state licensing boards—now merged into one—and the Association of American Medical Colleges have held their annual meetings in Chicago in conjunction with this annual conference.

III. Educational Standards

In 1904 two educational standards were established by the Council. One of them, suggested for immediate adoption by colleges and licensing boards, advocated an admission requirement of a four-year high school education, a four-year medical course of at least thirty weeks of actual work each year, and the passing of an examination before a licensing board. The other, an "Ideal Standard" intended for adoption at a later time, advocated a preliminary education of one year of college work in addition to a high school education, a four-year medical course, and a fifth year to be spent by the student as an intern in a hospital. In 1909, a "model medical curriculum" was prepared by a special committee of 100 under the direction of the Council. In 1913 a schedule of subjects to be included in the one-year collegiate course was prepared by a special committee of the Council in conjunction with a similar committee of the Association of American Medical Colleges. In February, 1917, after an extensive correspondence with college presidents, university examiners and with other educational experts, a special committee of the Council prepared a suggestive schedule of subjects for inclusion in a two-year premedical college course. This standard has been widely endorsed by colleges and universities and by the Association of American Medical Colleges.

The Council's work in connection with the above standards has had a profound influence not only on medical schools but also on general education. (*a*) In 1910 the Council collected information preparatory to publishing a list of accredited high schools, but on learning that the United States Bureau of Education was willing to publish it, the Council's data were turned over to that Bureau. (*b*) With the increase of the entrance requirements of medical schools to two years of college work, it became important to know which of the thousand or more institutions bearing the name of "college" or "university" were worthy of recognition as such. The Council, therefore, has been cooperating with the various agencies having to do with the standardization of colleges in an effort to secure a reliable list of approved institutions. Since 1917 the Council has published two tentative lists of colleges and junior colleges which have been approved by the North Central and Southern Associations of Colleges and Secondary Schools and the Association of American Universities. Similar organizations in other sections of the country are being urged to adopt similar lists so that a list of all colleges in the country which are worthy of approval can be listed.

IV. Preliminary Education

(*a*) In 1904 only about 25 per cent. of all medical schools were actually requiring a four-year high school education as their minimum requirement for admission. In that year the Council urged that all medical schools adopt that standard as a minimum.

(*b*) In 1904, also, the requirement of one year of college work was urged for future adoption. Educators at first thought it could be generally adopted by Jan. 1, 1908, but on account of conditions in the South, the time was extended to Jan. 1, 1910. It was made a requisite for the Class A rating on Jan. 1, 1914.

(*c*) In 1907 an extensive correspondence with colleges of arts and sciences revealed the fact that a requirement of two years of college work would fit in better with the scheme of collegiate education in the United States. It harmonized with the arrangement for the six-year combined course adopted by many universities for the degrees of B.S. and M.D.; it provided time for other useful subjects and culture courses, such as psychology, modern language, more English, etc., and avoided unnecessary friction in the acceptance of high school credits. It was found also that the two-year standard would place premedical education in this country on a par with that required in the leading foreign countries. In 1916, largely through the efforts of the Council, the two-year requirement had been adopted by forty-six medical schools and by seventeen state licensing boards, which justified the action taken in that year by the House of Delegates instructing the Council to make it a requisite for the Class A rating, beginning Jan. 1, 1918. This standard of preliminary education is now required for admission by every medical college rated in Classes A and B by the Council and has been adopted by thirty-two state licensing boards. This higher requirement by medical colleges is not "on paper only," since all colleges are now sending reports showing the entrance qualifications of their students, which enables the Council to verify the data in each individual case.

The increase in the standards of preliminary education and the adding to the medical course of a year of hospital work bring the completion of the medical course by the student at a too advanced age. This makes it important for a further cooperation by the Council with educational agencies in an effort to shorten the period of elementary and secondary education so as to save two years of the student's time. This will bring education in the United States more into conformity with systems of education in other leading countries.

V. Inspection and Classification of Medical Schools

(*a*) The first tour of the inspection of medical schools was made by the Council during the session of 1906-1907, when 162 medical schools were existing. On the basis of the data collected, the colleges were graded on a civil service basis on a scale of 100 per cent. and were classified in accordance as they obtained a rating: A, above 70 per cent.; B, between 70 and 50 per cent., and C, below 50 per cent. This classification was read at the annual conference in 1907 and in the same year to the House of Delegates of the American Medical Association. It was not published, but each medical college was notified in regard to its classification.

(*b*) The second tour of inspection was made during the session of 1909-1910, which included also the medical schools of Canada. At that time there were 144 medical schools in the United States and 8 in Canada. During the previous four years, 40 medical schools had ceased to exist, including 24 which had merged with others and 16 which became extinct. During the same time, however, 22 new institutions had been organized, making a net reduction of 18 colleges. It was during this second tour of inspection by the Council that Mr. Flexner prepared his report for the Carnegie Foundation. In fact, most of the inspections on this tour were made jointly by Mr. Flexner and the Secretary of the Council. The classification based on this inspection was included in the Council's report to the House of Delegates and was ordered published.

(*c*) The third inspection of medical schools was made during 1911-1912. The institutions rated in Class A were subdivided between those rated in A + and others in A, mainly because the institutions in the latter division had not voluntarily adopted the higher entrance requirement. In most instances, however, there were other serious defects.

(*d*) The fourth general inspection, which also included the colleges of Canada, was made during the session 1913-1914. At this time practically all colleges had adopted the requirement of one year of collegiate work for admission, so that the A + classification was discontinued and the colleges, as formerly, were grouped in Classes A, B. and C.

(*e*) A fifth classification had been planned for 1914 but was postponed owing to the general adoption of the one year of collegiate work for admission by a large number of institutions. It was decided to allow the medical schools time for readjustment under the higher standard. The reclassification was then planned for 1916, but was further postponed to 1918, owing to the rapidly increasing number of schools which were adopting the two-year standard of collegiate work which went into effect for all Class A medical schools Jan. 1, 1918. Then came the confusion due to the war, which made it advisable to further postpone the general reclassification. The time now seems opportune to make another general inspection and reclassification of all medical schools.

CHART 1.—MEDICAL SCHOOLS AND ENTRANCE REQUIREMENTS

This chart shows (heavy line at the top) the total numbers of medical schools existing in the various years. The chart also shows the numbers of medical schools requiring for admission (horizontal shading, indefinite, [illegible] high school education; (vertical shading) one [illegible] llege work and (heavy shading) two years of [illegible] k in the years indicated respecively by the vertical lines.

Requiring for admission (*a*) a high school education *or less;* (*b*) one year of college work; (*c*) two or more years of college work.

During the visits to medical colleges, in cities where two or more medical colleges were existing, mergers were urged by the inspectors so that in each instance one invariably stronger and better equipped medical school might result. By the end of 1918 the total number of medical schools had been reduced from 162 to 85 and of the latter number all but 6 had adopted the requirement of two or more years of collegiate work for admission. As stated in former reports, this country in 1904 had more medical schools than all the rest of the world. Between 1904 and 1919, therefore, the supply had been reduced to more nearly the normal number for the needs of the United States, but on the other hand, the institutions were greatly improved, not only in their entrance requirements but also in every other respect. The reduction in the numbers of medical schools and the progress in the adoption of higher entrance requirements are shown in Chart 1. It will be noted that great progress had already been made—both in the reduction in the total number of medical colleges and in the greatly increased number which had adopted higher entrance requirements—before 1910 when Mr. Abraham Flexner's report was published by the Carnegie Foundation for the Advancement of Teaching. With all due credit to the Carnegie Foundation for that excellent report and for the beneficial effect it produced in attracting public attention to the needs of medical education, it will be remembered that the Foundation suggested no standards and published no classification of colleges. As clearly shown in the chart, the great changes in medical education had their beginning in, and are mainly due to, the efforts of the organized profession, the American Medical Association, to put its own house in order.

VI. IMPROVING MEDICAL EDUCATION

(*a*) With the higher entrance requirements better qualified students are being enrolled in the medical schools. The campaign for improvement carried on by the Council has resulted also in providing a better medical training than was furnished in earlier years. As a result of the investigations and classifications and the publicity given to the conditions found more endowments for medical education were secured, better medical buildings were erected, new and improved laboratories were added, better equipment was provided and larger staffs of expert all-time laboratory teachers were employed.

(*b*) A careful study and revision of the medical curriculum has resulted in a better apportionment of time to the various subjects of the curriculum so that those subjects are now being taught in a more logical sequence.

(*c*) Medical faculties are better organized, which means that there is a better working organization of the instructors by departments—those teaching anatomy, physiology, chemistry, medicine, surgery, etc.

(*d*) During the fourteen years better and closer relations have been established between medical schools and hospitals; methods of clinical instruction have been greatly improved by the division of classes into small sections for ward work, clinical clerkships, etc.

VII. THE COUNCIL'S WORK AND THE WAR

Attention was called in the Council's report last year to the result of its work in connection with the world war. The facts are briefly emphasized as follows:

(*a*) Of the 20,678 students who graduated during the last six years, 15,025, or 72.6 per cent., were admitted under the higher entrance requirements, received their training in and graduated from the Class A medical schools, in which the great improvements in recent years had been most pronounced. It is the graduates of these recent years who in the largest proportions entered the government medical services. As a result, the American soldiers and sailors were attended by a larger proportion of medical officers who had had a modern medical training than they would have obtained had it not been for the Council's campaign for an improved medical education.

(*b*) At the headquarters of the American Medical Association, in the Council's files, the Students' Register and the Biographical Index, there is information regarding medical students and graduates which is not available elsewhere. This information was placed at the service of the Surgeon-General and as a part of the routine in the commissioning of medical officers, lists of applicants were sent to the Association for verification of their graduation and license. In 1917, through the possession of the Students' Register, unanswerable arguments were advanced favoring the exemption of medical students from the draft and, as a result, the Medical Enlisted Reserve Corps was established.

(*c*) The data available made it possible also to publish the Honor Roll and to conduct an energetic campaign toward securing the enlistment of larger numbers of physicians in the government medical services.

VIII. Graduate Medical Instruction

The world war has emphasized the great need of better facilities for graduate medical instruction in the United States. Such facilities were in great demand by medical officers as they were being released from active duty since that presented an excellent opportunity for them to take up certain courses of graduate study before returning to active practice. Improved facilities for graduate work are also important to meet the demands of our neighbors in the Spanish countries of Central and South America. The development of graduate work is an important subject to consider in connection with the efforts to standardize hospitals.

IX. Medical Cults

An important matter, which affects the relationship between the public and the practice of medicine and which is a problem directly concerned with medical education and medical licensure, is the existence and practice of the various pseudomedical cults, represented by osteopaths, chiropractors, naprapaths, spondylotherapists, neuropaths, psycultopaths, etc. Most of the teaching institutions turning out such practitioners have been inspected by the Secretary of the Council while on his various tours of inspecting medical schools. Files of information in regard to these institutions have been kept, which include catalogs, printed literature, circular letters, inspection reports, etc. The problem has been given sufficient study so that the following reliable statements can be made:

(*a*) The only logical argument to be made against practitioners of these cults is their lack of education. Such training as they have received has been in institutions requiring little or no educational qualifications for admission, and under faculties made up almost entirely of those who have not had a complete medical training. Graduate nurses could, with far greater justice, ask the right to treat human disorders than could the followers of these cults, because nurses are largely taught by physicians and secure their training in hospitals where all types of disease are treated by physicians.

(*b*) Before the recent improvements were made in medical education, many of the medical schools were very little better, from the standpoint of buildings, equipment and teaching facilities, than the better pseudomedical cult institutions. In the former, however, all instructors were those who had received a training in all the branches of medicine. Under the greatly improved conditions brought about in the last fifteen years, there is now so marked a distinction between the education and training of physicians as compared with those of the cult practitioners, that any intelligent layman can note the difference.

(*c*) The medical profession is justified in objecting to the various cults, not because of their peculiar systems of practicing, but because of their serious lack of education and the fact that they are seeking the right to practice as physicians without meeting the same educational standards with which physicians have to comply. If such practitioners wish to appear before the public as physicians and surgeons and to assume all responsibilities of such, then they should not object to being measured by the same standards and submitting to the same tests.

(*d*) The work of the Council in connection with low-grade medical colleges, drugless cult institutions and diploma mills has called attention to the lack of adequate safeguards over the chartering of educational institutions in the various states. In all but a few states any group of individuals for a small fee can secure a charter to open an educational institution and to grant all the degrees in the category, no questions being asked in regard to ability, financially or educationally, to furnish the education usually required for such degrees. Attention to the need of such safeguards was called by the Secretary in his report to the Council in 1916. Reprints of this report were sent to the educational authorities in each state, and a growing interest is being manifested toward the securing of the laws needed to establish such safeguards.

K. Hospital Standardization

(*a*) The "Ideal Standard," established by the Council in 1904, included among its requirements a fifth year to be spent by the student as an intern in a hospital. The Council, therefore, has always had a special interest in the number and character of hospitals. Since 1905 brief reports have been obtained each year from all hospitals as a basis for the lists published in the successive editions of the American Medical Directory. The information included merely the name, character and location of the hospital, the number of beds and the name of the superintendent. Copies of the hospitals' annual reports were asked for and were received from many of the larger hospitals. Much information was obtained from other sources regarding the reputation of the various institutions. Information in the Biographical Index gave other important data regarding the qualifications of the physicians on the hospital staffs. During the various tours of inspection, hospitals connected with medical schools were inspected by the Secretary of the Council, and first-hand information obtained regarding the number of interns and the character of their training.

(*b*) During 1912-1913 a carefully worded questionnaire was sent to 2,424 hospitals having twenty-five or more beds. Reports were received from 2,185, and of this number 852 were regularly using interns, providing places for 3,006 interns.[1] The report showed that the hospitals did not provide sufficient places for the 3,981 students who graduated in that year. Based on the information from this questionnaire and from the inspections made, the Council published in 1914 its first provisional list of hospitals considered in position to furnish acceptable internships. With the revisions made by state advisory committees, only 532 hospitals w[illegible] [illegible]m-mended in this first list, and internships i[illegible] able for 2,148 graduates each yea[illegible] begun and continued by the

(*c*) A second survey was [illegible] [illegible]nued during 1915. New ad[illegible] in the student's time. [illegible] various state medic[illegible] United States more into c[illegible] committees—th[illegible] of education in other leading countr[illegible] tematically [illegible]ACTION AND CLASSIFICATION OF MEDICAL SCHO[illegible] limited extent inspec[illegible] the advisory committees and teaching hospitals were inspected by the Secretary. The list of hospitals based on this second survey, which was published in August, 1916, was much more reliable than the first, and contained the names of 687 hospitals which provided internships for 3,340 graduates each year—more than could be supplied. By this time, as a result of the constant agitation by the Council, the intern year had been adopted as a requirement for the degree by eight medical schools and as a prerequisite for the license by eight licensing boards.

(*d*) The third survey of hospitals was begun in April, 1918. The state advisory committees were strengthened, or their membership renewed, through correspondence with state medical associations. The third questionnaire was sent to 1,126 hospitals, and an abundance of up-to-date information has been secured from this and other sources. Annual reports from the majority of the institutions have been obtained, and reports from hospitals are pouring in, giving the names of the physicians who are members of the attending and consulting staffs.

---

WORK OF THE PAST YEAR

THE THIRD SURVEY OF HOSPITALS

In October, 1918, there were in the United States 6,440 hospitals having ten or more beds, or a total capacity of 758,442 beds. The distribution of these by states is shown in Table 1. Of these hospitals, 4,927 have from 10 to 100 beds; 817 have from 100 to 200; 447 have from 200 to 500, and 277 have over 500 beds.

TABLE 1.—HOSPITALS IN UNITED STATES

State	Total No.	10 to 100 Beds	101 to 200 Beds	201 to 500 Beds	500 or More Beds	Total Beds	Hospitals Having or Seeking Interns

Washington	133	111	13	5	4	11,188	10	1,801
West Virginia	75	65	5	2	3	6,246	10	711
Wisconsin	218	150	45	17	6	20.965	23	2,313
Wyoming	28	26	.....	2	.....	1,252	3	179
Totals	6 440	4.927	800	456	257	758,442	1,126	270,401
Percentage	100.0	76.5	12.4	7.1	4.0	100.0	17.4	35.6

From the 6.440 hospitals reports showed that only 1.126, or 17.4 per cent. desired or were using interns. A special questionnaire was sent to these 1,126 hospitals and 1,005 responses have been received. Of these replies, 801 included statements in sufficient detail to permit their use in the tabulations shown in Tables 2 and 3 and in Chart 2.

Blanks inquiring data in regard to interns sent to all hospitals brought the information that 5,342, or 82.6 per cent., did not use interns, and only 1,126, or 17.4 per cent., were using or desired to have them. These 1,126 hospitals, however, include the larger institutions, and have 35.6 per cent. of the total bed capacity.

There are 274 more hospitals desiring interns than were listed in 1913, and 439 more than were listed in 1916. These have a total number of 270,401 beds (including eighty-four hospitals for the insane, with 97,421 beds). At the rate of thirty beds per intern for the general hospitals and a total of 174 interns in the state hospitals, places are provided for 5,940 interns or resident physicians, as compared with 3,566 in 1913 and 4,057 in 1916. This shows the remarkable increase in the appreciation of and demand for interns; it shows also the utter impossibility of graduating a sufficient number of medical students to meet the demand, even if we should multiply by four the number of physicians now graduating annually from our medical schools; it shows the necessity of employing house physicians, or of providing special assistants, who will do much of the work heretofore devolving on the intern.

Of the 6,440 hospitals in the United States about a year ago, a special questionnaire was sent to the 1,126 which had reported that they were using or seeking interns, replies have been received from 1,040. Of these replies, 801 gave specific replies to the questions asked. These replies in regard to the character of the hospital, hospital equipment and records have been tabulated and are show in Tables 2 and 3.

CHARACTER OF HOSPITALS

Of the 801 hospitals from which replies were received, 636, or about 80 per cent., are general hospitals, the remainder being devoted to the twelve special lines, as shown in Table 2.

EQUIPMENT OF THE HOSPITAL

The questions in regard to equipment applied mainly to the pathologic and clinical laboratory and its equipment to make certain examinations and analyses, the roentgen-ray laboratory and the work it is equipped to perform, and the employment by the hospital of expert anesthetists and dietitians. The number of hospitals replying in the affirmative to each question is indicated in the table, and the data are so arranged that for each state the totals may be seen, as well as the totals for the entire country. The bottom line gives the percentages of hospitals which are equipped in the various lines indicated. It will be seen that nearly all hospitals have laboratories equipped for the simpler chemical examinations of blood, urine and bacteriologic examinations, while to a less extent they are equipped to make gastric analyses, tissue examinations, total nitrogen determinations and serologic examina-

and as a part of the routine in the commissioning of medical officers, lists of applicants were sent to the Association for verification of their graduation and license. In 1917, through the possession of the Students' Register, unanswerable arguments were advanced favoring the exemption of medical students from the draft and, as a result, the Medical Enlisted Reserve Corps was established.

(*c*) The data available made it possible also to publish the Honor Roll and to conduct an energetic campaign toward securing the enlistment of larger numbers of physicians in the government medical services.

VIII. Graduate Medical Instruction

The world war has emphasized the great need of better facilities for graduate medical instruction in the United States. Such facilities were in great demand by medical officers as they were being released from active duty since that presented an excellent opportunity for them to take up certain courses of graduate study before returning to active practice. Improved facilities for graduate work are also important to meet the demands of our neighbors in the Spanish countries of Central and South America. The development of graduate work is an important subject to consider in connection with the efforts to standardize hospitals.

IX. Medical Cults

An important matter, which affects the relationship between the public and the practice of medicine and which is a problem directly concerned with medical education and medical licensure, is the existence and practice of the various pseudomedical cults, represented by osteopaths, chiropractors, naprapaths, spondylotherapists, neuropaths, psycultopaths, etc. Most of the teaching institutions turning out such practitioners have been inspected by the Secretary of the Council while on his various tours of inspecting medical schools. Files of information in regard to these institutions have been kept, which include catalogs, printed literature, circular letters, inspection reports, etc. The problem has been given sufficient study so that the following reliable statements can be made:

(*a*) The only logical argument to be made against practitioners of these cults is their lack of education. Such training as they have received has been in institutions requiring little or no educational qualifications for admission, and under faculties made up almost entirely of those who have not had a complete medical training. Graduate nurses could, with far greater justice, ask the right to treat human disorders than could the followers of these cults, because nurses are largely taught by physicians and secure their training in hospitals where all types of disease are treated by physicians.

(*b*) Before the recent improvements were made in medical education, many of the medical schools were very little better, from the standpoint of buildings, equipment and teaching facilities, than the better pseudomedical cult institutions. In the former, however, all instructors were those who had received a training in all the branches of medicine. Under the greatly improved conditions brought about in the last fifteen years, there is now so marked a distinction between the education and training of physicians as compared with those of the cult practitioners, that any intelligent layman can note the difference.

(*c*) The medical profession is justified in objecting to the various cults, not because of their peculiar systems of practicing, but because of their serious lack of education and the fact that they are seeking the right to practice as physicians without meeting the same educational standards with which physicians have to comply. If such practitioners wish to appear before the public as physicians and surgeons and to assume all responsibilities of such, then they should not object to being measured by the same standards and submitting to the same tests.

(*d*) The work of the Council in connection with low-grade medical colleges, drugless cult institutions and diploma mills has called attention to the lack of adequate safeguards over the chartering of educational institutions in the various states. In all but a few states any group of individuals for a small fee can secure a charter to open an educational institution and to grant all the degrees in the category, no questions being asked in regard to ability, financially or educationally, to furnish the education usually required for such degrees. Attention to the need of such safeguards was called by the Secretary in his report to the Council in 1916. Reprints of this report were sent to the educational authorities in each state, and a growing interest is being manifested toward the securing of the laws needed to establish such safeguards.

X. Hospital Standardization

(*a*) The "Ideal Standard," established by the Council in 1904, included among its requirements a fifth year to be spent by the student as an intern in a hospital. The Council, therefore, has always had a special interest in the number and character of hospitals. Since 1905 brief reports have been obtained each year from all hospitals as a basis for the lists published in the successive editions of the American Medical Directory. The information included merely the name, character and location of the hospital, the number of beds and the name of the superintendent. Copies of the hospitals' annual reports were asked for and were received from many of the larger hospitals. Much information was obtained from other sources regarding the reputation of the various institutions. Information in the Biographical Index gave other important data regarding the qualifications of the physicians on the hospital staffs. During the various tours of inspection, hospitals connected with medical schools were inspected by the Secretary of the Council, and first-hand information obtained regarding the number of interns and the character of their training.

(*b*) During 1912-1913 a carefully worded questionnaire was sent to 2,424 hospitals having twenty-five or more beds. Reports were received from 2,185, and of this number 852 were regularly using interns, providing places for 3,006 interns.[1] The report showed that the hospitals did not provide sufficient places for the 3,981 students who graduated in that year. Based on the information from this questionnaire and from the inspections made, the Council published in 1914 its first provisional list of hospitals considered in position to furnish acceptable internships. With the revisions made by state advisory committees, only 532 hospitals were recommended in this first list, and internships in them were available for 2,148 graduates each year.

(*c*) A second survey was [illegible] nued during 1915. New a[illegible] two years of the student's time. [illegible] various state medi[illegible]n in the United States more into c[illegible] committees—th[illegible]stems of education in other leading countri[illegible] tematically [illegible]TION AND CLASSIFICATION OF MEDICAL SCHO[illegible] limited extent inspection[illegible] the advisory committees and teaching hospitals were inspected by the Secretary. The list of hospitals based on this second survey, which was published in August, 1916, was much more reliable than the first, and contained the names of 687 hospitals which provided intern[illegible] immediately begun [illegible] 3,340 graduates each year—more than could [illegible] a result [illegible]visory committees appointed by th[illegible] of the constant [illegible]cal associations were secured. The state advisory committees were strength[illegible] by [illegible] their membership renewed, through correspondence with state medical associations. The third questionnaire was sent to 1,126 hospitals, and an abundance of up-to-date information has been secured from this and other sources. Annual reports from the majority of the institutions have been obtained, and reports from hospitals are pouring in, giving the names of the physicians who are members of the attending and consulting staffs.

---

[1] See "Preliminary Report on the Standardization of Hospitals," American Medical Association Bulletin, March 15, 1915, p. 316.

ample room not only for the work of the American Medical Association, but also for that being done by the American College of Surgeons, the Catholic Hospital Association, and for what may be planned by the American Hospital Association and other organizations. Efforts are now being made to secure the cooperation of all agencies so as to bring about the greatly needed improvement in the hospitals of the United States.

At the conference on medical education last March, a paper on hospital standardization was presented by Dr. A. R. Warner, president of the American Hospital Association. At the close of the discussion a resolution was adopted urging the creation of a conference which would include representatives of all factors interested in development and standardization of hospitals, and urging that a meeting be called at an early date under the auspices of the American Medical Association. In accordance with this resolution, a special meeting was called by President Bevan, which was held in Chicago on Monday, April 21. Representatives were present from the American Medical Association, American Hospital Association, the American College of Surgeons, the Association of American Medical Colleges, the Catholic Hospital Association, the American Nurses' Association, the American Association of Hospital Social Workers, and the Federation of State Medical Boards of the United States.

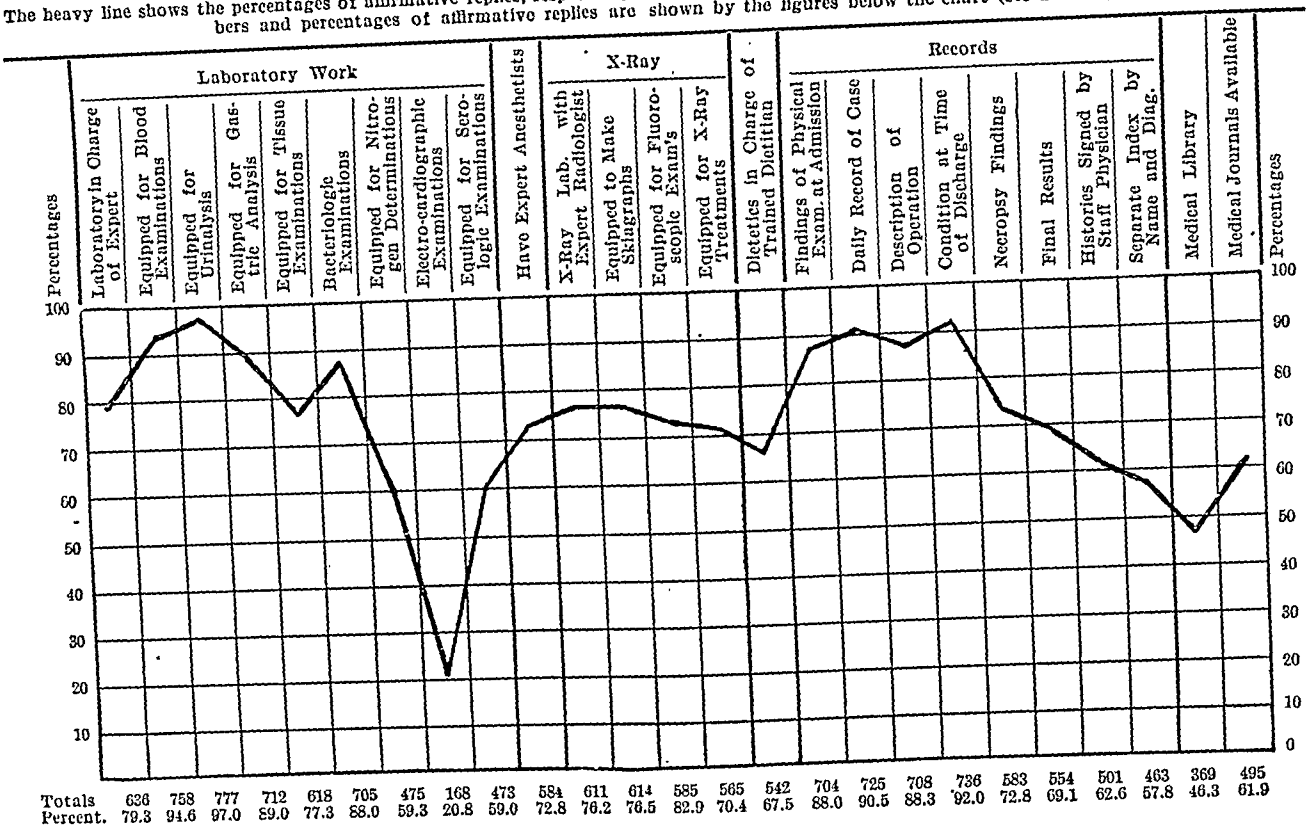
Following a series of reports from the several organizations, it was voted that an American Hospital Conference be organized, to be made up of two representatives of each of the organizations named, and two each also from the American Association of Industrial Physicians and Surgeons and the medical departments of the United States Army, Navy and Public Health Services—altogether twelve organizations and twenty-four delegates. An executive council of three members was created to have in charge the direction of the work connected with the drafting of a constitution and other essentials which will be presented at the first meeting of the conference to be held in connection with the annual meeting of the American Hospital Association in September. A second meeting will be held in connection with the annual conference of the Council on Medical Education at Chicago in March, 1920. The members appointed on the executive council were Dr. A. R. Warner, president of the American Hospital Association, Cleveland, chairman; Dr. John M. Dodson, dean of the Rush Medical College, Chicago, and Dr. Walter L. Bierring, secretary of the Federation of State Medical Boards, Des Moines, Iowa. Through this hospital conference all the various factors interested in the development and standardization of hospitals will have a voice in the formulation of standards for use in the investigation and measurement of such institutions.

ESSENTIALS FOR AN INTERN TRAINING

Based on the abundance of data obtained from the various hospitals from an extensive correspondence with hospital superintendents, deans of medical schools, representatives of state licensing boards and others, the Council has prepared the following tentative outline suggesting the equipment and facilities needed by a hospital and the regulations to be put into effect in order that it may provide a satisfactory training for its interns:

CHART 2.—EQUIPMENT AND RECORDS OF 801 HOSPITALS USING INTERNS

The heavy line shows the percentages of affirmative replies, respectively, to the several questions indicated by the headings. Both the total numbers and percentages of affirmative replies are shown by the figures below the chart (see Table 3).



TENTATIVE SCHEDULE OF ESSENTIALS IN A HOSPITAL FOR THE SATISFACTORY TRAINING OF INTERNS

I. The Staff of the Hospital

1. There must be an organized staff.
2. Staff physicians should be men of unquestionable integrity both professionally and morally.
3. They should be proficient in the special fields in which they work in the hospital.
4. They should give personal attention to the patient under their charge, some member of each department visiting the hospital every day, and every member of the staff should visit the hospital at least once each week.
5. They should assume an obligation to direct and supervise the training of the interns admitted to the staff.
6. (a) A clinical conference of the attending staff and the interns should be organized and held at frequent intervals at least monthly, at which new cases and the problems they

present should be discussed. (*b*) There should also be clinical and pathologic conferences, for the attending staff and interns where the antemortem clinical picture is presented and compared with the necropsy findings. (*c*) There are also hospital medical societies at which staff members and interns are encouraged to present cases which have been worked up from the clinical point of view and on which they have read up the available literature.

II. The Equipment of the Hospital

1. A pathologic department equipped with facilities for necropsies, this work to be in charge of an expert, who may be a member of the staff skilled in such work.

2. One or more small clinical laboratories for work by the intern in direct connection with the wards for the routine examination of blood, urine, stools and gastric contents. Within the hospital there should be also a clinical laboratory in charge of an expert who shall be responsible for the more technical, chemical, bacteriologic and serologic work and examinations.

3. A roentgen-ray department in charge of an expert roentgenologist and equipped to do roentgenographic, fluoroscopic and therapeutic work.

4. A working medical library containing a fair supply of modern standard text and reference books, the better medical journals, and suitable charts and models. Bound volumes of the better medical journals for recent years constitute a very satisfactory part of a hospital medical library.

5. Adequate provision for the housing and recreation of interns.

III. Histories and Records

1. Complete histories should be taken, giving the patient's complaint, physical examination at time of admission to hospital, laboratory findings, description of operation, if any, daily record of case, condition and date when discharged from the hospital, end-results, and, in case of death, necropsy findings if necropsy is performed.

2. The histories should show, by signatures or initials, the persons writing them or parts of them. This will show not only the work of the intern, but also the supervision over it by members of the attending staff. In hospitals where senior medical students act as clinical clerks, it should be the duty of the interns to supervise and correct the histories written by the students and the records they keep.

3. The records should be carefully kept and placed in charge of a trained historian. This will not only guarantee better records and better care from the patient's point of view, but also will actually protect the hospital itself, especially in certain medical legal cases.

4. The records should include an alphabetical index of the patients, another arranged by diagnoses, and, for surgical cases, one arranged from the standpoint of the regional part involved. For the alphabetical index cards might be used which would show the end-results, sometimes referred to as the "summary" of the case.

IV. The Work of the Intern

1. The hospital should have a set of printed rules and regulations defining the rights, duties and privileges of the interns which should be furnished to each intern or posted in a conspicuous place.

2. All of the work of the interns should be under the careful supervision of staff physicians. This is essential, not only to correct errors—such as may be expected from his lack of experience—and thereby protect the patient, but also that the intern may receive instruction through his errors and be able to avoid their repetition.

3. The writing of histories in connection with the examination of patients. (See III, 2, above.)

4. Clinical laboratory work. This work might well be divided into two portions, the first to be obtained in the ward laboratory work in connection with the examination and care of patients, the other portion to be obtained in the general laboratory in assisting the expert pathologist in the more technical, chemical, bacteriologic and serologic work. (See II, 2.)

5. Roentgen-ray work: The intern should receive a reasonable amount of instruction in the therapeutics of the roentgen ray and also in the interpretation of roentgen-ray plates and fluoroscopic findings by an expert roentgenologist or a qualified member of the hospital staff.

6. Anesthetics: The intern should obtain experience in the administering of various kinds of anesthetics under expert supervision.

7. Dietetics: The intern should be given instruction by a trained dietitian, or qualified staff member, in the feeding of both infants and adults as required in various diseases or conditions.

8. Maternity work: Before finishing his intern service, the intern should have had experience under supervision not only in the delivery of normal maternity patients but also in the more common abnormal cases.

9. Necropsies: The intern should obtain an experience in making necropsies either under the direction of or by assisting the hospital pathologist.

10. In his progress through his junior and senior service, the intern should assume, under careful supervision, an increasing responsibility in the diagnosis, daily observation, care and treatment of the patients under his service. This experience and responsibility should be in connection with as large a variety of cases as possible and include at least such diseases as are commonly met with by the average practitioner of medicine.

11. The intern should obtain a practical experience in the applying of surgical dressings in connection with the care and treatment of patients. As he progresses in his surgical intern service he should be authorized under careful supervision to perform not only minor surgical operations but also some of the more common major operations. In major operations, the attending surgeon should stand by, or assist the intern. Experience in connection with accident service is, likewise, highly desirable.

12. The number of patients assigned to each intern and the routine work required of him should not demand more than eight (at most, ten) hours daily. He must have ample time to study and read up on his cases both in the interest of his patients and for his own educational progress.

13. The intern service should extend through at least twelve months, and may to great advantage be continued through eighteen months or two years.

V. Miscellaneous

1. Prominent educators are about equally divided in favoring the rotating and nonrotating services for interns. It is evident, however, that each may represent an extreme which should be avoided. If the intern's work is limited to either medical or surgical services, the intern should be encouraged to remain an additional year so as to complete both services. Special hospitals, such as those for diseases of the eye, ear, nose and throat, should preferably select their interns from those who have already completed a service in a general hospital.

2. Where the internship is being taken as a prerequisite to graduation, the evaluation and grading of his hospital work should be done by the medical school from which he is to secure his M.D. degree, either by direct conference with his resident superior, or indirectly, through a series of reports furnished for this purpose by the hospital.

3. The hospital should have an average of not less than twenty-five patients to be eligible to train an intern. To provide for a rotating service in laboratory, medicine and surgery, therefore, a hospital should have at least seventy-five beds and three interns.

4. In hospitals having four or more interns, they should preferably begin their work at different times and pass through junior and senior service. The services are sometimes further subdivided into first and second junior and first and second senior services. Such an arrangement keeps in the hospital a constant supply of experienced interns. This is not only the interest of the patient, but also enables senior interns to instruct juniors.

5. In hospitals having 100 beds or more, in addition to the interns, there should be a full-time resident physician, who has had at least one year's intern experience. It shall be his duty to supervise the work of the interns, particularly at times when no staff physicians are in attendance at the hospital. Even hospitals having less than 100 beds (public ward patients) will furnish their interns with a more valuable training if a resident physician is employed to superintend the professional work in the hospital.

VI. Object

It is believed that an internship obtained under the provisions herein made will prove to be for the best interests not only of the intern and of the hospital, but also of the patients and of the public at large.

Present Enrolment in Medical Schools

Reports from the eighty-five medical colleges which conducted classes during the session of 1918-1919, show that the total enrolment of medical students is approximately 12,090, or 1,540 less than for the session of 1917-1918. The reduction is mainly in the freshman classes of which the total enrolment is approximately 2,810 for the present session, as compared with 4,283 for the previous session. There were twenty-five medical schools also which last fall for the first time enforced the requirement of two years of collegiate work for admission. Such schools were expected to report smaller enrolments in the freshman classes. The decrease, however, was not due altogether to higher entrance requirements. Usually in colleges which had become readjusted under the higher entrance requirements the enrolments have shown an increase or have returned to their previous numbers. This year, however, of the sixty colleges reporting which put into effect the higher requirements in 1916 or previous years, thirty, or 50 per cent., reported a decrease in the number of freshman students. This unusual decrease was due clearly to the volunteering or drafting of premedical students for military service during 1917-1918. With the beginning of another session following the return of soldiers and sailors to civilian life, the enrolments of students in our medical colleges will return to their prewar proportions. Since all colleges have now passed the crisis of the higher entrance requirements, it is quite likely also that the total enrolments in medical schools will show an increase over this and previous years.

Result of the War on Medical Education

In order to bring medical education in the United States on a par with that of other countries, the general requirement of two years of collegiate work for admission was essential. With this increase and with the diminution of the number of medical schools, a decrease in the total enrolment of medical students was to be expected. That this country has about reached the lowest point in such enrolments, however, may be seen from Table 4. Following the readjustment under the higher entrance standards naturally the increase in the enrolments would be noted first in the freshman, then the sophomore, junior and senior classes, respectively, in four successive years, and the table bears this out in that the lowest ebb in the four classes appears for the first year students in 1915, for the second year students in 1916, for the third year students in 1917, and for the fourth year students in 1918. Had normal conditions continued all classes would now be showing an increase and there would have been a resulting increase in the total enrolment for all classes. That this has not been the case is due to the unusual conditions resulting from the world war and the part our country has had in it.

No Scarcity of Physicians

The unusual demand for medical officers naturally created a temporary scarcity of physicians for hospitals and civilian needs, but this was to be expected, and was merely a parallel to the scarcity of experts in other lines of human activities—a scarcity which will undoubtedly disappear following the return of medical officers to a civilian status. The world war has called attention to special needs in every line of human endeavor. No previous war had so involved the entire world or so hazarded the very existence of practically every civilized government. In no previous war was such extensive use made of those who had reached the highest attainments of human skill and ingenuity. The urgency and extent of this demand naturally drew attention to the scarcity of those who were qualified to render service along highly technical or specialized lines. So in medicine there was an unprecedented demand for physicians of exceptional qualifications and skill in the various specialties, such as pathologists, bacteriologists, psychiatrists, brain surgeons, oculists, etc. Here, likewise, the urgency of the demand has forcibly revealed the fact that the supply of physicians having such skill is comparatively limited.

This revelation, however, is not a criticism of medical education of the past, but lays emphasis on the possibilities and aims of medical education in the future. The improvements of the last fifteen years were directly in line with these needs. This country was never so well supplied with physicians who were so thoroughly trained or as skilled in the specialties as at the time it entered the world war.

The war has rendered a great service in revealing the possibilities and benefits that will result from higher attainments in medicine. This shows the necessity of continuing the campaign for improvements not only in undergraduate but also in graduate medical education. If the highest attainments are of such vital importance in great national crises, how much greater will be the service to the public whether there be peace or war.

TABLE 4.—ENROLMENTS OF MEDICAL STUDENTS FOR SEVEN YEARS, SHOWING VARIATION IN NUMBERS BY CLASSES

Year	Freshmen	Sophomores	Juniors	Seniors	Totals
1913	4,564	4.093	3,639	4,444	17,015
1914	4,684	3,981	3,807	3,955	16,507
1915	3,373	3,919	3,675	3,864	14,891
1916	3,582	3,094	3,559	3,727	14,022
1917	4,107	3,117	2,866	3,674	13,764
1918	4,283	3,521	2,893	2,933	13,630
1919*	2,810	3,448	3,158	2,674	12,090

* Estimate.

The line drawn through the table underscores the figures for the freshman, sophomore and junior years which represent the lowest ebb in the enrolment in the respective classes. The number of seniors in 1918 would likewise have been the lowest enrolment for that class had it not been for the exceptional circumstances due to the war. While the figures for 1919 are estimated they are very nearly accurate since reports from all but a few colleges were obtained.

Proportion of Physicians to Population

The supply of physicians in this country is still greater in proportion to the population than that of any other civilized country. According to the sixth edition of the American Medical Directory, completed in 1918, the United States had 147,812 physicians. The total population of the United States, as given in an estimate of the Census Bureau in 1918, was 105,253,300—which is one physician for every 712 people. Various reports regarding the proportion of physicians to population in the countries of Europe just prior to the war show that in those countries the proportion ranged from one to 1,500 to one to 2,500. This country, therefore, still has twice as many physicians to population as the most favored country of Europe

There is, however, an increasing demand for physicians for various lines of work—a demand which can be met only by continuing the high standards of preliminary and medical education now generally adopted, and by further improving our facilities for both undergraduate and graduate medical teaching. This demand for physicians is increasing for the following reasons:

(*a*) The work in public health and preventive medicine is being rapidly expanded especially along the lines of quarantine work, sanitary inspection, medical inspection of schools, etc.

(*b*) There is an increasing demand for physicians who specialize in laboratory diagnostic work. Such positions now carry larger salaries and are attracting an increasing number of medical graduates.

(*c*) There is an increasing demand also for full-time teachers in medical schools for both laboratory and clinical subjects. These places are not only paying better salaries than formerly, but are attractive to many on account of the opportunity for scientific experimentation and research.

(*d*) The rapid development of insurance has brought an increased demand for physicians who devote themselves entirely to such work. With the extension of industrial insurance this demand is bound to be still further increased.

(*e*) The increased study and research being given to tuberculosis, to mental diseases, to cancer and other like problems, is attracting many who would otherwise continue in the practice of medicine.

(*f*) The tremendous interest being aroused for the development of hospitals in smaller cities and rural communities will create a demand for recent graduates as resident physicians in such hospitals. Through the inability to secure interns, hospitals will be inclined to employ resident physicians for a series of years on progressively increased salaries.

(*g*) In the reorganization and improvement of hospitals there is a growing demand for those to serve as superintendents who can combine their medical training with administrative ability.

Rural Communities

The chief complaint in regard to a scarcity of physicians comes naturally from the sparsely settled rural communities where physicians could not make a livelihood because of the difficulties of intercommunication and transportation. With the advent of the telephone, the automobile, improved roads and interurban transportation, however, conditions in rural communities have gradually improved. The physician can now more easily reach the patient in the rural district in emergency cases. Now in a large number of cases the patients go to the physicians in the smaller cities nearby. The number of hospitals in or near these rural districts is rapidly increasing, and this will enable each physician to care

---

[1] Of the 81 physicians licensed in Arkansas, the Regular Board licensed by examination 7 Class A, 28 Class B and 7 miscellaneous graduates and by reciprocity 5 Class A, 4 Class B and 4 miscellaneous graduates, a total of 13. The Eclectic Board licensed by examination 26 Class C graduates. The Homeopathic Board reported no candidates licensed either by examination or by reciprocity.

[2] Of the 105 graduates of Class C colleges licensed in California, 77 were graduates of osteopathic colleges which are not generally recognized as medical colleges by state licensing boards, and 34 of these were required to take only an oral examination. Altogether 133 osteopaths were admitted to the examination for licensure as physicians and surgeons and 77 were so licensed.

[3] Of the 24 graduates of Class C colleges licensed in Colorado, 21 were graduates of osteopathic colleges, institutions inferior in most respects to Class C medical schools which are reported as not recognized in Colorado.

[4] Texas licensed 3 Class C graduates by examination (although Class C colleges are reported as not recognized) and 18 Class C graduates (including 11 osteopaths) were licensed by reciprocity, a total of 21.

This table shows the classification of the colleges from which most of the phys[illegible] licensed in 1918. Graduates of colleges [illegible] to 1907 who were examined, and all reciprocit[illegible] prior to 1907, are unclassified and included [illegible] It was in 1907 that the Council on Medical Education completed its first classification of all medical colleges.

It will be seen that five states accepted Class C graduates through reciprocity where they did not license any by examination. On the whole, however, 287 were licensed by examination where only 54 were registered through reciprocity.

By both examination and reciprocity, the largest numbers of Class C graduates were licensed in California, 116 (including 77 osteopaths); Colorado, 24 (including 21 osteopaths); Missouri, 52; Arkansas, 26 (all by the Eclectic Board); and Texas, 21. The largest numbers of Class B graduates were licensed in Illinois, 161; California, 69; Tennessee, 58; New York, 44; Ohio, 33, and Arkansas, 32.

Of all physicians licensed, 2,456, or 58.7 per cent., were graduates of Class A medical schools; 682, or 16.3 per cent., from Class B schools; 342, or 8.2 per cent., from Class C schools, and 705, or 19.2 per cent., from miscellaneous colleges.

for a larger number of patients and thereby make a better livelihood. The rural districts, therefore, will secure better trained physicians. Not only will there be a larger number of physicians, but there will be more skilled service.

Postgraduate Education

One of the benefits of the world war is that attenton has been called to the great importance of a better training of physicians, particularly along the line of the narrower specialties. A tremendous interest in postgraduate medical education has developed, therefore, not only in the United States, but also in European and other countries. In all our large cities there is an abundance of clinical teaching material which would be most useful for graduate medical instruction, but which is widely scattered, and not readily accessible to the student. It must first be cataloged and administered by a single organization so that information regarding the work can be obtained by the student by applying at a single place rather than at several widely separated places, which is the condition which prevails at present. A report has just been received indicating that in New York City a movement is on foot to pool all of the hospital facilities for the development of a great scheme for postgraduate medical education, and doubtless similar movements will soon be evident in other large cities. The closer friendship and harmony between the United States and the sister republics of Central and South America—another result of the war—will be further extended if through the development of postgraduate medical education students from South American countries will be induced to and can readily obtain instruction in such subjects as they may desire. In this connection, the exchange of professors between this and European countries and the proposed exchange of clinical clerks and clinical assistants are steps in the right direction. The arrangement should be extended also to the countries of Central and South America.

Progress in Medical Licensure

Since 1904 the Council has had as one of its regular functions the collection and tabulation of statistics which are published in the State Board Number of The Journal in April of each year. These tables have had a large influence in the improvement of both medical education and medical licensure. One table published with the statistics the last two years is reproduced herewith in Table 5. It shows the classification of the colleges from which each physician graduated who was licensed either by examination or reciprocity during 1918. Graduates of medical school which ceased to exist or which merged with other schools prior to 1907 are included among "miscellaneous" candidates, since no medical schools were classified prior to 1907 following the tour of inspection made by the Council on Medical Education. This table will show the members of the House of Delegates just how many physicians licensed in their respective states during 1918 were graduates of Classes A, B and C medical schools and whether the people of those states are being adequately protected against the output of low-grade colleges. Special attention is called to the footnotes, which give information relating to certain states.

Work for the Coming Year

As intimated in the foregoing report, the lines of work to be emphasized by the Council on Medical Education during the coming year are:

(*a*) Continuation of the work in connection with medical education and licensure by securing information from medical colleges and state boards and publishing it as usual in the Educational and State Board Numbers of The Journal. This includes also the routine work in connection with the Medical Students' Register and the Biographical Index of Physicians.

(*b*) The continued agitation in regard to improvements in preliminary and medical education and in medical licensure through the annual conference.

(*c*) Continued efforts with agencies having to do with the standardization of colleges of liberal arts and sciences in the effort to secure a complete list of approved colleges of arts and sciences and junior colleges which are in position to give satisfactorily two years of premedical college work.

(*d*) A complete reinspection of all medical colleges, which is essential preparatory to a revision of our classification. This is needed so as to aid a number of colleges which have made numerous improvements; it is neecessary also so as to ascertain whether all medical schools are keeping up to the required standards of excellence.

(*e*) An inspection of all hospitals undertaking to train interns. This can be done in connection with the inspection of medical schools and will in no way conflict with the investigation of hospitals in general being made by the American College of Surgeons and other agencies. It will, in fact, be in harmony with that work.

(*f*) A furtherance of the efforts toward securing the cooperation of all agencies interested in the improvement and standardization of hospitals, toward the main object sought—that the physicians on their staffs may be able to render the best service to the patients in the communities which the hospitals serve.

(*g*) A continued study of the facilities for postgraduate medical education in the United States and publicity regarding the needs of further development along that line. This will include efforts to secure closer relations between the United States and other nations, including those of Central and South America, in both undergraduate and postgraduate medical education.

(*h*) Continued efforts to secure safeguards in each state over the chartering of educational institutions.

In Conclusion

This report shows the lines along which the work of the Council on Medical Education has been developed during the last fifteen years and the direct connection of that work with what still remains to be accomplished. The experiences of the war have emphasized other needs in medical education particularly in the clinical part of the medical course and in the better training for specialists. Improved relations with other countries in medical education; the investigation and standardization of hospitals (with a cordial cooperation of all agencies interested) and the further development of postgraduate medical education—all deserve to have careful consideration and energetic action.

Respectfully submitted,

The Council on Medical Education,
John M. Dodson, Acting Chairman,
Robert C. Coffey, William D. Haggard,
William Pepper, Isadore Dyer,
N. P. Colwell, Secretary.

Report of the Council on Scientific Assembly

Dr. E. S. Judd, Minnesota, Chairman, presented the report of the Council on Scientific Assembly, which was referred to the Reference Committee on Sections and Section Work.

The report follows:

To the Members of the House of Delegates of the American Medical Association:

At the Chicago session, last year, the Reference Committee on Sections and Section Work submitted the following in its report to the House of Delegates:

> "We find on referring to the program of the Scientific Assembly and to the meeting of the House of Delegates that there are nineteen separate and distinct sections of our association meeting during five days, as follows: House of Delegates, general meetings, scientific exhibits, and sixteen scientific sections. We therefore appreciate the significance of this statement that much time is devoted to scientific work, leaving very little for pleasure and getting acquainted.
>
> "We also find that a resolution has been handed to us requesting consideration of the creation of a new section on industrial physicians and surgeons, making additional scientific work. There would then be twenty distinct parts of the association meeting during the five days. We find also, on referring to the program, that there are 562 speakers listed to address the physicians in attendance. This does not include meetings of the House of Delegates or meetings on Wednesday and Thursday evenings.

"As a result of all this, we find it impossible to make any definite recommendation to become operative at the next session, and as this involves every member of the Association in attendance, we would recommend that this House of Delegates direct the Council on Scientific Assembly to carefully study this problem and form a definite plan of procedure for future meetings. We would also recommend that the committee be directed to forward the suggested plan of procedure to each member of the House of Delegates, for the next session, at least two weeks prior to the first day of the meeting of the House, and that the report of the Council be submitted to the House of Delegates at the next session for definite action."

The House of Delegates adopted the report of this Reference Committee and the Council on Scientific Assembly, in compliance with this direction of the House of Delegates, arranged for, and held a conference of Secretaries of Sections at the headquarters of the Association, in Chicago, February 6. At this conference, the acting Secretaries of all the Sections were in attendance with the exception of the Secretary of the Section on Dermatology. In addition, the Chairman of the Section on Ophthalmology, the President and the President-Elect of the Association, the Speaker of the House of Delegates and the Secretary of the Board of Trustees, were present, as were all the members of the Council on Scientific Assembly, with the exception of Dr. Roger S. Morris, who was absent from the country on military duty.

There was an earnest discussion of the subjects presented in the foregoing recommendations of the House of Delegates and other matters pertaining to the Scientific Assembly, as well as the plans for the Victory Meeting, the annual session of 1919.

By mutual consent of the Secretaries of all the Sections, it was agreed to make trial at this annual session of dividing the sections into two groups; one group to meet in the morning hours and the other group to meet in the afternoon hours on Wednesday and Friday. It was further mutually agreed that all the Sections shall meet on Thursday morning, in order to place that afternoon at the disposal of the Board of Trustees for large general meetings, to be addressed by foreign physicians in attendance at the annual session as delegates, representing the medical profession of the countries allied to the United States in the World War. In this way, arrangements will be carried out so that each of the Sections will hold but one meeting on each of the days assigned for Section meetings, instead of two meetings as at previous annual sessions. For the annual session of 1919, in accordance with the foregoing plan the following Sections will meet during the morning hours of Wednesday, Thursday and Friday: Practice of Medicine; Obstetrics, Gynecology and Abdominal Surgery; Laryngology, Otology and Rhinology; Stomatology; Preventive Medicine and Public Health; Genito-Urinary Diseases; Orthopedic Surgery and Gastro-Enterology and Proctology. The following Sections will meet during the afternoon hours on Wednesday and on Friday, and along with the Sections already named during the morning of Thursday: Surgery, General and Abdominal; Ophthalmology; Diseases of Children; Pharmacology and Therapeutics; Pathology and Physiology; Nervous and Mental Diseases; Dermatology; Miscellaneous Topics.

At this conference of the Secretaries of Sections, the following rules were formulated, to be submitted to the several Sections for adoption as standing rules of the Sections. These standing rules, it will be noted, define with more exactness provisions which already are incorporated in the By-Laws of the Association.

1. No paper shall occupy more than fifteen minutes in its presentation before the section (Section II, Chapter XI of the By-Laws, "The time allowed for the presentation of a paper before a section shall be limited to fifteen minutes," shall be mandatory) with the exception that the time may be extended by the unanimous consent of those present when the speaker is an invited guest of the section. The section shall not exercise its privilege to extend the time for the discussion of a paper beyond the time allowed (five minutes) but this time limit shall be mandatory.

2. With the exception that the reader of the paper may be permitted to close the discussion, a Fellow shall be permitted to take part in the discussion of a paper once, and only once.

3. Any Fellow who desires to discuss a paper shall be required to give, in writing, his name together with his home and local annual session address to the Secretary of the section before he is given the floor. This rule shall be strictly enforced when for the first time at an annual session a Fellow takes part in the discussions of the section.

4. Section 2, Chapter XII, "Each author shall hand his paper to the Secretary of the section immediately after it is read" shall be amplified and emphasized, and shall be construed to require that each author must present to the Secretary of the section a finished copy of his paper before he is permitted to present his contribution to the section.

5. Each author shall be required to send a full synopsis of his paper to each of those listed in the official program to open the discussion of the paper, and these synopses shall be mailed to those assigned to open the discussion at least ten days before the first day assigned to the meetings of sections.

6. The Secretary of the section shall inform himself as to whether or not each member of the executive committee of his section expects to be in attendance at each annual session of the Association and shall transmit to the chairman of the section the information he receives, reporting both who of the executive committee of the section plans to be in attendance, and also who will *probably not be present.*

7. The Secretary of the section shall mail a copy of the rules of the section to each Fellow who is assigned to a place on the program of the section.

8. The rules of the section shall be binding on the Secretary of the section who shall have no option but must enforce them.

The Council on Scientific Assembly assigned two meetings of the Section on Miscellaneous Topics for the 1919 annual session for the presentation of a program on Industrial Medicine and Surgery, and appointed the following officers for these meetings: Chairman, Dr. Harry E. Mock, Chicago; Vice Chairman, Dr. David L. Edsall, Boston; Secretary, Dr. Otto P. Grier, Cincinnati.

The Council recommends to the House of Delegates that the maximum number of papers, including addresses, on the program of any one section shall hereafter not exceed twenty-five. In order to make this recommendation effective, the Council suggests that, if the House concurs in this recommendation, Section 12, Chapter XI, of the By-Laws shall be amended so that it shall read:

The number of papers including addresses, on the program of any section shall not exceed twenty-five.

The Council further recommends to the House of Delegates that the standing rules for the guidance of the Council on Scientific Assembly which were adopted at New York, June 17, 1917, shall be amended by deleting the second of these rules and modifying the present third and fourth rules so that the standing rules for the guidance of the Council on Scientific Assembly shall read:

1. The term "unit" shall signify a single meeting of a section at an annual session.
2. The sections of the Scientific Assembly shall be limited at each annual session to the maximum number of three units.
3. The sections shall not hold more than one meeting on each of the days of the annual session during which section meetings are held.
4. The Council on Scientific Assembly shall apportion the morning and afternoon units at each annual session to the several sections.

In compliance with the request of the Section on Genito-Urinary Diseases, the Council recommends that the name of this section shall be changed to the Section on Urology, and that in order to make effective this recommendation, Section 1, Chapter XI, Item 13, of the By-Laws shall be amended by deleting the words: "13. Genito-Urinary Diseases" and substituting therefor the words "13. Urology."

Respectfully submitted,

E. S. Judd, Chairman,
George H. Simmons, Roger S. Morris,
J. Shelton Horsley, Alexander R. Craig.

Report of the War Committee of the American Medical Association

Dr. Hubert Work, Colorado, Chairman, presented the report of the War Committee, which was referred to the Reference Committee on Reports of Officers.

The report follows:

To the Members of the House of Delegates of the American Medical Association:

Since the report submitted to this House of Delegates last June, according to the records of the Association, the applications for commissions in the Medical Corps of the Army were: June, 2,416; July, 2,841; August, 3,814; September, 4,171; October, 3,113, and during November, the month of the Armistice, 632; total, 16,987 commissions from June 1, 1918, to the cessation of hostilities.

The American Medical Association has been the center of information concerning medical military matters for physicians. Replies to individual inquiries have involved the activities of several of the departments at the Association headquarters, and letters to individual physicians during the period of hostilities frequently numbered over 100 each week. In addition, since last June, more than 5,000 pamphlets covering information pertaining to entrance into the Medical Corps were distributed in response to individual requests. The expense involved, including printing, postage and other items, has been borne by the Association.

The American Medical Association supplied state and county organizations with detailed information concerning the physicians in their own communities who were available for civil and industrial practice, and has cooperated with these branch organizations in enlisting the services of additional physicians where the needs of a locality could not be met by physicians still remaining in civilian practice in these communities.

On the suggestion of the officers of the Association, the Provost Marshal-General requested the Surgeon-General of the Army to assign a medical officer to the office of the Provost Marshal-General, in order that that medical officer might act as an advisor on medical questions arising under the Selective Service regulations. Col. Frank Billings was first assigned to this position. From this beginning, the medical division of the Provost Marshal-General's office was created on August 1 last, which, when the armistice was signed, had a personnel of four medical officers and five enlisted men and clerks. The functions of this medical division related to the selection and induction of registrants into military service, and included the recording and computing of the statistical data incident to that work. This medical division in the Provost Marshal-General's office brought about intimate working relations between these two offices. Through the coordination which it made possible, the examinations of registrants by the Selective Service Boards and those made at the cantonments and camps by the army medical officers were standardized. Your Committee congratulates the Association, through this House of Delegates, on the nationwide service which the Association has rendered, especially in that its organization was made available for assembling and proving medical data to the executive heads of several Federal departments which required the cooperation and assistance of the medical profession both in caring for the force under arms and in the execution of the Selective Service regulations. The work of the Association elicited the following comment in the Second Report of the Provost Marshal-General to the Secretary of War, on the Operation of the Selective Service System to Dec. 20, 1918. After announcing that the medical profession is credited with supplying 4,246 of the 13,564 members of the local boards (31.3 per cent.), and in addition, that there were established 155 district boards on each of which there was at least one physician, and 1,319 advisory boards with a personnel of 9,577, the report states:

"At this point a tribute is due to the American Medical Association. From this Association came the suggestion for medical advisory boards and cordial assistance in their selection. THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, with a circulation of 66,000 copies, has been a valuable medium of information between this office and the medical men who discharged the duties of the profession to the government through the draft. The medical profession has responded and served in a devoted manner that has received universally favorable comment. It is gratifying to note the part which the Association has taken in thus assisting to raise our great Army, as well as its valuable contribution to the war generally."

The Surgeon-Generals of the Army, of the Navy and of the Public Health Service, have given similar recognition of the cooperation which the Association has rendered their corps.

In submitting this, its final report, the members of the Committee desire to express to this House of Delegates their appreciation of the opportunity to serve the profession and the Nation which appointment on the Committee afforded.

Respectfully submitted,
HUBERT WORK, Chairman,
A. R. MITCHELL,
FRANK BILLINGS,
WENDELL C. PHILLIPS,
Ex-officio { ARTHUR DEAN BEVAN, President,
A. R. CRAIG, Secretary,
GEORGE H. SIMMONS,
Editor of THE JOURNAL.

ADDENDUM

Before proceeding with the business of the House, the Speaker announced the following Reference Committees:

SECTIONS AND SECTION WORK

George D. Head, Chairman	Practice of Medicine
S. R. Roberts	Georgia
J. B. Blake	Massachusetts
L. S. McMurtry	Kentucky
John Ridlon	Section on Orthopedics

RULES AND ORDER OF BUSINESS

J. Rilus Eastman, Chairman	Indiana
G. Wythe Cook	District of Columbia
S. W. Welch	Alabama
Joseph R. Morrell	Utah
F. LeMoyne Hupp	West Virginia

MEDICAL EDUCATION

J. H. J. Upham, Chairman	Ohio
J. R. Phelps	U. S. Navy
George D. Stewart	New York
Edward B. Heckel	Pennsylvania
Franklin E. Murphy	Missouri

LEGISLATION AND POLITICAL ACTION

Thomas S. Cullen, Chairman	Maryland
Clarence Pierson	Louisiana
Charles E. Humiston	Illinois
Frank Y. Gilbert	Maine
Charles S. Huffman	Kansas

HYGIENE AND PUBLIC HEALTH

J. W. Schereschewsky, Chairman	U. S. P. H. S.
H. A. Royster	North Carolina
C. D. Selby	Ohio
L. M. Halsey	New Jersey
V. G. Vecki	California

AMENDMENTS TO CONSTITUTION AND BY-LAWS

Floyd M. Crandall, Chairman	New York
F. A. Winter	U. S. Army
P. W. Tomlinson	Delaware
J. M. Aiken	Nebraska
I. C. Chase	Texas

REPORTS OF OFFICERS

Hugh T. Patrick, Chairman	Section on Nervous and Mental Diseases
Rock Sleyster	Wisconsin
J. N. Hall	Colorado
Edgar A. Hines	South Carolina
J. E. Lane	Connecticut

CREDENTIALS

C. P. Meriwether, Chairman	Arkansas
D. E. Welsh	Michigan
Charles R. Hume	Oklahoma
F. T. Kidder	Vermont
John C. Rockafellow	Iowa

MISCELLANEOUS BUSINESS

W. B. Russ, Chairman	Texas
Southgate Leigh	Virginia
F. T. Rogers	Rhode Island
Thomas H. Halsted	New York
H. B. Gibby	Pennsylvania

After announcing the Reference Committees, the Speaker called on the Vice Speaker, Dr. Dwight H. Murray, New York, to take the Chair.

Previous to delivering his address, the Speaker stated that the Ad Interim Committee by postal vote approved the appointments by the Board of Trustees of a special Committee on Revision of the Pharmacopeia.

Address of the Speaker, Dr. Hubert Work

The Speaker then delivered the following address, which was referred to the Reference Committee on Reports of Officers:

To the House of Delegates of the American Medical Association:

After fifteen consecutive years of service in this House, as a Delegate, on the Judicial Council, and as Speaker, may I say a word intended to be constructive in character.

This Association has long been an ornament to the medical world. The probity of its officers, its scientific attitude and unequaled Journal have compelled its recognition as the finality of ethical, scientific medicine in the United States.

MILITARY SERVICE OF THE ASSOCIATION

The world war called to it, tried it and proved the quality of its organization and personnel. Thirty-five thousand physicians volunteered for military service and went away. Twenty thousand volunteered for draft service at home. Sixty thousand more volunteered for limited service, to do what they could. More than 100,000 physicians from our total of 148,000 served, or pledged themselves for service.

The question of the profession's loyalty to its country has been answered. Its loyalty to organized medicine is on trial.

The uniformed 35,000 returning find their personal relations changed. Communities adapted themselves to their absence; they became unnecessary. The routine practice of medicine had contracted itself, for much of it relates to betterments in health, rather than to immediate conservation of life. While returned physician-soldiers are received with pride and often with affection, business is not emotional but is governed by the laws of business. Many physicians not only gave their time to the government, but their niche in the community also, and must hew a new one there or elsewhere. Some put away with their uniforms the spurs of ambition and the anticipation of future successes. Our sons, who went away as boys, return as men. The world has changed them and changed to them. These new men will have new thoughts and do new things, they have been reconstructed and will in turn readjust this Association and also their relations to the practice of medicine.

A NEW ERA

Thoughtful men agree that we are entering on a new era in medicine which will compel the closest interrelation between physicians, hospitals, nursing and the public. It is not probable that practice will again be followed as heretofore. The time is passing when the personality and skill of a single physician will satisfy his patrons, or command a fee measured only by the patient's ability to pay, for skill is no longer limited to a few. Teamwork of physicians and the evolution of the hospital, which provides all domestic and medical service, has given the public an economic idea which will hereafter direct the practice of medicine. Cities and large towns already have their hospitals; rural communities soon will have, state aided no doubt, for it is a short step from state care of the insane to the state care of all sick. The greatest future concern of this Association may be its direction and oversight of hospitals; the practicable achievments of its five councils, if you please, brought to bear on common centers for the cure of the sick.

BUREAU OF HOSPITALS

Should this House recommend to the Trustees that a Council on Hospitals be created?

Such a bureau should comprehend hospital architecture, construction, plumbing, organization, contagious diseases, general medicine, surgery, interns, practical nursing, trained nursing—in short, a bureau of information for the standardization of all detail relating to the hospital care of the sick. Standards fixed by a permanent council of experts, directed by this Association, would compel hospital directors to comply with their requirements in order to secure a coveted rating. It would avoid the expensive canvass and tedious propaganda now being conducted jointly by the American Medical Association and the American College of Surgeons. The weight of the Association's influence behind this movement, directed in the field by selected full-time men, would give the public assurance and a point of appeal on hospital questions.

Duties of this bureau would be: consultations with municipalities proposing to build; with industrial companies, planning sick care for their employees, and with state governments. Proprietary and sectarian hospitals contemplating enlargements or troubled by incompetent management would welcome the efficiency expert of such a bureau, while philanthropists could know that their bequests were worthily bestowed and would be honestly conserved, as by a trust.

GRADED SCHOOLS

Our public schools are teaching trades. Premedical training should assume direction there also. The necessary mental discipline may be obtained from studies essential to medicine, and time should not be occupied on branches studied only for a degree. Courses in the grades, high schools and colleges are so loosely knit that the first year in high school and college is largely wasted in fitting for the last three years. Could one year be safely clipped from the grades, one from the high school and one from the college course of those who would study medicine?

We have an inactive joint subcommittee with the National Educational Association which might well functionate on the pressing question of premedical education. A majority of common school boards in the United States have one or more physician members. This Association can bring about through them new educational policies it may choose to inaugurate.

UNDERGRADUATE MEDICAL EDUCATION

It is evident that the relentless pressure of this Association for higher college and professional standards, with their time and financial exactions on the one side and the decrease in disease through preventive medicine on the other, are grinding between them students and physicians of average opportunities.

Medical requirements for practice demand at least seven years of schooling beyond the high school. In some universities, two degrees and nine years' time are demanded for graduation. That included in the average medical college curriculum costs so much time and money that only the rich can attain it. The crossroads communities will soon have no qualified physician, and from necessity will revert to the opportunist and the midwife. Should undergraduate schools undertake to finish specialists in medicine, presumably the function of postgraduate schools?

The primary function of a physician, to cure the sick, is submerged by the scientific ambition to diagnose rare diseases or a few ailments, with an inevitable loss of perspective necessary to the accomplished diagnostician. Failure to gain practical knowledge of the simple things in medicine tremendously depreciates recent graduates. American medical colleges are graduating medical scientists, and our hospitals, nursing specialists, both technicians and both out of reach of the family of average means.

NURSES

We should recognize that conditions confronting communities affecting physicians, apply equally to nurses. Certain training schools require for graduation a high school diploma for admission followed by three years' training. The average nurse is graduated with a feeling that her period of service has ended and her reign is begun. This is an intolerable economic attitude. The average householder cannot afford to employ servants for servants indefinitely, and he is already looking to the medical profession for relief in home care for his sick.

The public needs practical nurses, trained in cleanliness and taught to do what is necessary to be done for the comfort of the household, including its sick. There ought to be provided six months or more schooling in every small city, for teaching girls who have good average ability but not necessarily overschooling to do the common every day things in nursing. It was done in a war emergency recently and is a practical suggestion.

NEED FOR THE GENERAL PRACTITIONER

The general practitioner of medicine must come back, and a temporary substitute for the stricken mother must be trained and qualified for duties associated with the sick in the home. If we fail to initiate these changes intelligently, economic necessities will do it blindly, and we will submit to it but not direct it.

The American Medical Association is directed by the highest type of scholarly men, but it must not be operated exclusively for them and should address itself to the necessities of a majority of our medical men, who need help most and who are doing the most of medical work. It would appear that this Association could do more at its annual meetings than discuss scientific papers.

The medical profession of the United States numbers about 148,000. Of these, 82,000 are members of the American Medical Association, 70,000 are subscribers to The Journal, 45,000 are Fellows of the Association, and approximately 4,000 attend its annual meetings. For some years these have been relatively stationary figures and call for inquiry into the causes.

The question is frequently asked: "Is the organization fostered so that its Journal may thrive, or is The Journal the agent of the Association?" The presentation of able papers to be printed and made accessible to 70,000 physicians who do not attend annual meetings has great value, but is that enough for 80,000 organized physicians, to accomplish? It is apparent that we must answer to the public many questions, all of which are embraced in the general case, Shall the American Medical Association assure to the public, qualified physicians, nurses and standardized hospitals, at prices it can afford to pay?"

PHYSICAL EDUCATION OF CHILDREN

The physical examination of registrants for the late war emphasized the importance of medical supervision of grade schools for physical correction. Almost 30 per cent. of registrants appearing before local boards were rejected for military service. Nearly 9 per cent. of those inducted were rejected at camp. Thirty-eight per cent. of young American men were disqualified because of vicious habits of development, correctable defects and preventable diseases, easily detected by a schoolteacher and readily righted in their incipiency by physicians. The physical development of schoolchildren is more necessary than textbook education—a duty which should be suggested and accomplished by physicians as an organized movement, again made possible to this Association through its medical members of school boards, and its joint committee with the National Educational Association.

AMERICAN COLLEGE OF SURGEONS

Unstinted commendation is due the American College of Surgeons for its intelligent energy and liberal expenditures of money directed toward the standardization of hospitals. It has fixed for itself also the important duties of compelling the qualifications of its surgeon members and of creating a sentiment to prevent the secret division of fees. The fixing of qualifications for surgeons may be safely left with this college, as its requirements are exacting. The standardization of hospitals is urgent. The secret splitting of fees requires two parties to accomplish it. Let those who refer cases wash their own hands also.

AMERICAN DENTISTS

Our kinsmen of the profession of dentistry took their place in the world crisis, without hesitation and to great purpose. They demonstrated their quality as professional men, their loyalty as Americans, and their right to be recognized as a specialty in medicine.

The three essentials for a soldier are serviceable teeth, a good stomach, and strong, flexible feet. Organized dentistry saw to it that the first necessisty was promptly, cheerfully and gratuitously provided for registrants.

STATE AND SECTION SECRETARIES

State and section secretaries each should hold annual midwinter meetings for the discussion of problems pertaining, respectively, to the development of the state and county branches and the scientific assembly. The reason for this is obvious—the intimate connecting up of the American Medical Association with its component and constituent societies in an attempt to dispel the lethargy that is settling on medical organizations.

I hope that the House will consider at this session the future relations of the American Medical Association to the public in its entirety, and particularly to outlying communities. If you believe it to be desirabe, set apart a few hours, resolve the House into a committee of the whole, freed from program and time exactions, for the discussion of ideas you doubtess entertain for the protection and advancement of the profession through this Association.

The American Medical Association must either become a reminiscence or adapt itself to the requirements of modern medicine as the future may apply it to arising conditions. The latter should be the vision of the House. I particularly wish to see this House of Delegates assume its rightful function in initiating and defining the policies of the American Medical Association.

I believe there are duties before the Association, professional rather than scientific, which will call for exceptional devotion, patient service and skilful guidance. But my official connection with you, which must soon terminate, has assured me that no body of men has keener insight, clearer vision, or higher motives. And as I thank you for your countless courtesies, may I also urge you to weigh well your responsibilities.

Address of the President, Dr. Arthur Dean Bevan

The Speaker then resumed the Chair and introduced Dr. Arthur Dean Bevan, Illinois, President of the Association, who delivered the following address, which was referred to the Reference Committee on Reports of Officers:

Mr. Speaker and Members of the House of Delegates:

I desire to present quite informally to you some of my impressions of the work of the Association, with some suggestions that naturally grow out of these impressions.

In the first place, during my connection with the Association, especially during the last year as President of it, I have been very greatly impressed by the soundness of our scheme of organization. Our organization is thoroughly representative and democratic. It represents better than any other plan that could be devised the medical profession of the country. I feel, however, that few of us realize the enormous size of the task and the great responsibilities of the American Medical Association. To meet these responsibilities and to realize these possibilities for good, both for the profession and for the people of this country, we must have an imagination and a courage, and we must plan our organization to meet the much larger and broader requirements than any of us have as yet dreamed of.

The activities of the Association will increase in number and magnitude from year to year, and we must plan to anticipate this fact and build machinery to meet these very great demands as they are coming.

We already have, as Dr. Work has told you, more than 80,000 members; we shall soon have 100,000 members. We have created in the American Medical Association an instrument, the purpose of which is to give to the people of this country the benefits of modern scientific medicine. We have created an instrument with which we can elevate the standards of medical education and medical practice and conserve in the best sense the interests of the profession. We have created an instrument through which we can stimulate scientific medical research and improve the character of American medical literature.

The value of our scheme of organization was tested by the war. The organized profession of the country promptly met the demands of the government, and within a short time about 50,000 medical men and women responded to the call

MOSQUITOES AND CULICIFUGES

The surest and safest way to avert the menaces to human health and comfort which are presented by the mosquito lies in its eradication. However ideal diverse plans for this purpose may be, even the most enthusiastic hygienist will admit that they cannot be carried out except by a long, carefully conducted antimosquito campaign which will extend over years rather than days or weeks. Meanwhile, occasions arise when individuals and groups of men must be protected, if possible, from the annoyance and the dangers of mosquito bites. Here, as in so many other instances, wartime conditions have pointed to the urgent need. Troops compelled to travel through malarious regions, soldiers posted in places where mosquitoes abound, and civilians driven into the abodes of these insects, may demand immediate, though only temporary, protection.

The enemy which cannot be destroyed can sometimes be repelled. Herein lies the usefulness of the culicifuge—a preparation intended to ward off the attacks of mosquitoes. Recently many chemical preparations have been tested at the Lister Institute in London, with respect to their suitability for this purpose. Bacot and Talbot,[1] who undertook this important investigation, which also included the undoubtedly disagreeable task of serving as subjects for the tests, found a number of readily available mixtures that proved to be fairly satisfactory, although none gave complete protection. The method of testing them consisted in ascertaining the number of bites on treated and untreated bared arms from caged hordes of mosquitoes. The "treatment" involved coating the exposed arm from the wrist to the elbow with the alleged culicifuge. In this way some efficiency was demonstrated in preparations in which the active ingredients were oil of cassia and camphor, oil of cassia and peppermint, oil of eucalyptus and citronella with phenol, crude coke-oven naphthalene and camphor, light wood oil, and oil of turpentine, as well as a number of proprietary products of unrecorded composition.

From a practical standpoint it was found that fluid preparations were inconvenient and tended to be wasteful in application. Soap preparations, unless very soft, are apt to be difficult of economical use, and in either case are more readily dissipated by perspiration than waxy or greasy preparations. Culicifuges prepared with grease are more easily applied but are not so lasting as those put up with wax. Soft wax preparations, correctly adjusted to the temperature in which it is proposed to use them, are most suitable for outdoor use, especially in the case of troops. The retarding of volatilization caused by the admixture of the active ingredients with wax or grease is a distinct advantage, but care must be exercised in respect to the relative proportion of active substance to the base. The golden rule, Bacot and Talbot add, is to use as much of the active constituent and as small a quantity of the inert base as is consistent with convenient application and the prolonging of the period of efficiency, not, as most proprietary compounders appear to think, as little as possible of the active constituent.

The preliminary observations of the British entomologists indicate that the period of protection with products such as those here described cannot be depended on to extend over more than two hours. This may nevertheless be sufficient to offer an enormous advantage in certain regions. It has generally been assumed heretofore that the culicifuges act by presenting a repulsive odor to the insects. Bacot and Talbot favor the suggestion, however, that the protection afforded does not result from a dislike of the mosquitoes to the culicifuge but from its obscuring the attractiveness of the human odor. The mosquito season is at hand again with us, so that the new suggestions as to these tested palliative measures may be both timely and helpful.

MITOCHONDRIA

Microscopic anatomy, which is still diligently inquiring into the nature of cell structure, has recently shifted its interest in no small measure from the nucleus to the cytoplasm. As a result, a definite type of cytoplasmic granules now known as mitochondria, a term first introduced by Benda in 1899, has become recognized and has been extensively studied. E. V. Cowdry[1] has recently summarized our present knowledge concerning these bodies. They have a variety of shapes: sometimes they are filamentous or rodlike, and again pear-shaped or granular. While their size varies greatly in different cells and even in a single cell, it seems to be the rule that the cells of certain tissues in different animals have similar mitochondria. Cowdry believes that here is shown a correlation of cellular function and morphology.

The fundamental importance of mitochondria is evidenced by their wide distribution. They have been demonstrated in plants, from the thallophytes to the spermatophytes, and in animals, from protozoa to man. Within the cell these variable bodies are generally indefinitely arranged; in gland cells, however, they usually show a polar distribution. Cowdry suggests that this distribution may indicate cell polarity and form a basis for the interpretation, according to mitochondrial distribution, of the origin or position of intracellular activities. He also maintains that their position and relation with respect to other cell constituents may make them an index of the deviation from the normal in cells.

[1] Cowdry, E. V.: The Mitochondrial Constituents of Protoplasm, Contributions to Embryology, 8, No. 25, Carnegie Institution, Washington, 1918.

Some interesting data as to variations in the amount of mitochondria have been gathered. Wherever there is marked cellular activity, as in cytomorphosis and regeneration, the amount increases; but where cellular activity is lessened, it decreases. Again, these bodies occur in inverse ratio to the fat content of cells. If it be assumed that the fat content of cells increases as the respiratory activity diminishes, it is noted that mitochondria are associated with high degrees of respiratory activity. Chemically, these bodies are composed of a combination of phospholipin and albumin, as has been demonstrated chiefly by response to various stains and reactions to fat solvents, acids and certain salts. While closely similar in plants and animals, there is no doubt that the chemical composition varies slightly. The interest of modern physiologic chemistry in phospholipins happily makes possible in this case the correlation of physiologic chemistry and cytology, the importance of which Wilson[2] has so constantly emphasized.

The demonstration of the chemical nature of mitochondria has rendered untenable many of the older views of the genesis of fibrils, pigment, secretion, etc., from them. Tentatively, it may be said that they are closely related to the fat metabolism in the cells; but this is probably not their only metabolic relationship, since they seem to be present in plant and animal cells regardless of the type of metabolism. How essential a part they play in metabolism cannot be stated definitely at this time. As has been mentioned, they seem closely related to respiratory activity. Chemically they are well suited to change by oxidation or reduction. They are diminished in amount by agents that decrease respiratory oxidations, such as chloroform or ether. As mitochondria are a far more sensitive index of cell activity and injury than is the nucleus, they no doubt will prove of increasing interest in pathology. The studies of the mitochondrial content of the cells of the nervous system, the pancreas and the thyroid seem to be yielding promising results. As regards the characteristics and significance of mitochondria in tumors, Cowdry holds that the scattered observations so far at hand permit of no final statements. Here investigation of tumors in animals under controllable experimental conditions may prove of great value. Enough has been said to show that a new field for work has been laid open for the pathologic anatomist and microchemist.

GRADUATE MEDICAL INSTRUCTION IN THE UNITED STATES

During the last few months, reference has been made in The Journal to increased activities in the development of graduate medical instruction in England and France. Both of these countries have established what is termed an "Interallied Fellowship in Medicine,"[1] providing graduate courses for qualified medical officers of the allied countries having armies in Europe. In London an elaborate program has recently been adopted[2] which calls for a graduate medical association; cooperation of all medical schools; increased privileges for graduate students; a pooling of all hospital facilities, and the securing of cooperation of America and France. Paris also is endeavoring to make that city more prominent as a center of postgraduate medical instruction.

We note with interest these laudable efforts to develop graduate medical instruction in London and Paris, and will rejoice if these efforts are successful. At the same time, however, we must not overlook our own shortcomings in this particular field. For many years the United States lagged behind other countries in improving medical education, but has partly redeemed itself by the almost revolutionary changes in undergraduate medical education through which commercialism has practically disappeared. An equal or greater improvement is essential in graduate medical instruction. Private graduate schools are not satisfactory and do not meet the present-day requirements. Harvard, Pennsylvania, Minnesota, California and Tulane have established graduate medical schools, but in none of them has graduate teaching developed to the extent that it has in some European cities. In the large cities of this country the student is still compelled to wander from school to school or from hospital to hospital to find the courses desired. To obtain sufficient clinical material in a desired specialty he is compelled to seek courses in several institutions rather than in one, and even then usually finds that the courses are held at such times that he cannot register for them. As a consequence, he cannot utilize all his time without registering for courses he does not want. The usual result of his search has been a waste of time, a loss of objective, and disappointment.

In many of our large cities, an abundance of clinical teaching material is now going to waste which, with a proper organization, could be utilized in graduate courses to the great benefit of the medical profession, and ultimately to the public in the development of more skilled physicians. The situation in each city calls for (*a*) affiliation of all hospitals and schools having clinical teaching facilities; (*b*) organization of a single graduate medical school; (*c*) special provision for the needs and convenience of graduate medical students; (*d*) generous opportunities for the graduate student to develop skill by actually treating or operating on patients under competent instruction, and (*e*) the listing of all courses in such a manner that related courses do not conflict. Finally, when graduate medical instruction has been more satisfactorily developed, we should seek to cooperate with other countries in the exchange of teachers, clinical assistants and graduate students. Especially should there be a close cooperation with our Latin neighbors of Central and South America. The latter countries are showing a desire to establish both commercial and educational relations with the United States. In the lines of medical education, especially, everything should be done to encourage this desire and to make the relations beneficial and permanent.

GLYCURESIS VERSUS GLYCOSURIA

Not long ago we commented on the suggestion of S. R. Benedict[1] that progress in the study of carbohydrate metabolism would be more rapid if the term "glycosuria" were abolished. According to his contention, some sugar elimination, however small, takes place continuously through the kidneys. This contention has been advanced by others to explain the finding of reducing substances in the urine of presumably healthy persons. Since glycosuria implies a sudden point at which sugar appears in the urine, a term is needed to express the constant presence of sugar in normal urine and an excess of sugar elimination above normal limits. Benedict accordingly coined the expression "glycuresis" to signify the increased absolute elimination of sugar per hour as compared with the control period. The experimental data indicated that food ingestion is the controlling factor in physiologic sugar elimination.

These interesting conclusions were not entirely convincing owing to the paucity of observations on record. It must not be assumed that the physiologic urinary sugar content is significant because of its absolute value. The latter falls below the limits of all but highly delicate methods of analysis; indeed, it may be questioned whether the small amount of "reducing substance" detected in normal urines is in reality glucose.

In the midst of this uncertainty the evidence in favor of the views of Benedict has been supplemented by the observations of Bailey,[2] which seem to indicate that a normal person, when uninfluenced by food or fluid intake, has reducing substances present in equal concentration in both blood and urine. Following the ingestion of glucose, urine sugar parallels that of the blood up to the latter's concentration of from 0.16 to 0.17 per cent. As the blood sugar increases beyond this point the kidneys actively excrete sugar. This excessive excretion decreases as the hyperglycemia passes off. Glycuresis, says Bailey, is a kidney function and is excessive in diabetes and hyperthyroidism. It is greatly decreased in nephritis and with deficiency of the thyroid or hypophysis. The concentration of blood sugar at which glycuresis occurs varies in different individuals, and is influenced by disease, being abnormally low in early diabetes, high in diabetes of long standing, in nephritis, and with deficiency of the thyroid or hypophysis. Of late the blood sugar has received preeminent attention in the accurate determination of the capacity for carbohydrate metabolism. Perhaps the study of the urinary output will again claim an equal share of importance in the study of carbohydrate tolerance.

Current Comment

THE VICTORY MEETING

As this issue of The Journal goes to press the Victory Meeting is in session at Atlantic City. The registration up to 4 o'clock Monday was 1,265, and on Tuesday, over 3,000. The meeting, therefore, promises to be well attended, and the interest displayed by those physicians fortunate enough to be in attendance indicates a session of great scientific and practical importance. In this issue appear the minutes of the first meeting of the House of Delegates, Monday, June 9, and the address of the president, Dr. Alexander Lambert, New York, delivered Tuesday night. The remainder of the minutes, both of the House of Delegates and of the Scientific Assembly, will appear in the issue for next week.

THE PROTEINS OF RAGWEED POLLEN

The establishment of a relationship between hay-fever and the pollen of plants has brought about an unusual interest in the chemistry of the pollen grains. If the phenomena of this widely prevailing disease are to be referred correctly to the specific etiologic factors, it will become necessary to know what components of pollen are responsible for the morbid manifestations. Opinion has been somewhat divided on this point. Some have believed that the harmfulness of the pollen is due to a toxic agent of comparatively simple constitution, although the majority of the writers in recent years seem to be committed to the belief that some protein in the plant structures is at fault. Obviously, clarity could be infused into the discussion if the chemical components of pollen were known and isolated, so that direct experiments could be performed with them. Pollen is, however, not very readily obtainable in large amounts for investigation, so that progress has been slow. Recently Heyl[1] has obtained an albumin, a proteose and a glutelin from the pollen of the ragweed (*Ambrosia artemisiaefolia*). A mixture of the albumin and proteose was demonstrated to have antigenic properties, so that anaphylactic reactions could be brought about by them in animals. This observation is of interest in view of the earlier assertion that anaphylaxis cannot be produced with pollen extracts.[2] Various bases, including histidin, lysin, arginin and agmatin, are also present in pollen; but for the present it seems more likely that the potent factor in the untoward responses elicited by the grains is associated with their proteins, which ought to receive thorough investigation as a preliminary to the further development of immunologic or preventive measures for treating the harm attributable to them.

TOXIC MANIFESTATIONS OF ARSPHENAMIN

The death of the patient which has been observed in some instances to follow the administration of arsphenamin has occasioned much concern to those who are compelled to administer this potent drug in human therapy. Among the symptoms observed in these cases of acute collapse are dilatation of the heart and a fall in systemic blood pressure. So far as can be learned from animal experiments, there may be increased pulmonary blood pressure. The reaction of the internal organs seems to be variable. The occasional toxicity of preparations of arsphenamin has been attributed to intermediary compounds employed or arising during the process of manufacture. A number of these have been tested experimentally at the Hygienic Laboratory of the U. S. Public Health Service. The report is that they are not very poisonous and cannot account for the variable toxicity of different samples of arsphenamin which may or may not contain traces of one or more of them.[3] The possibility that the acute reactions often seen after arsphenamin administration in the clinic may be attributable to precipitates forming in the blood stream has also been suggested by several investigators; but it receives no support from the government pharmacologists. They charge the reaction to the alkalinity of the solutions used for injection and to the specific action of the arsphenamin itself. Wherever the real explanation of the unexpected toxicity may be proved to reside, the management of the symptoms of collapse is a question in practical therapy. Epinephrin has commonly been employed to combat the condition. Jackson and Smith[3] are, however, inclined to recommend a trial of tyramin in suitable cases. Hewlett[4] has already employed it as a blood-pressure raising substance in hypodermic doses of 60 mg. (1 grain). The systemic pressure does not rise so high and the danger of acute dilatation of the heart is not so great as with the intravenous injection of epinephrin, according to Jackson and Smith, but the effects of tyramin are much more lasting. These investigators are extremely cautious in their advice, however. While they are by no means sure that the use of the drug might in any degree decrease the number of fatalities that from time to time occur under the use of arsphenamin, yet in their own words, they believe it is more logical and more likely to be of real value in these cases than is any other drug with which they are acquainted. This conclusion is far from convincing; but when a real danger exists, every reasonable prospect of averting it deserves some serious consideration.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending June 6, there were 14,906 officers in the Medical Corps, a decrease of 400 from the previous week. The Medical Reserve Corps contained 2,061 officers. The total number of medical officers discharged since the beginning of the war is 17,355.

Legislation to Provide Civilian Medical Care for Soldiers on Furlough

The Secretary of War is authorized to arrange for the employment of civilian medical authorities and facilities for the care of officers and enlisted men of the army who require medical attention while on furlough, in a measure presented to Congress by Congressman Rogers of Massachusetts. It is required that the disability originate in the line of duty.

Promotions to Be Resumed

The Surgeon-General has been authorized, as have been other corps commanders, to resume promotions of officers under certain restrictions. For a time after the signing of the armistice no promotions were made, but the ban is off if requirements are met. The chief requirement is that the officer recommended for promotion must be performing the work of an officer for the rank for which he has been recommended.

General Hospitals Closed

U. S. General Hospital No. 18, Waynesville, N. C., and U. S. General Hospital No. 35, West Baden, Ind., have been officially closed.——The hospital at the U. S. Quartermaster Terminal, Sewell's Point, Va., is to be transferred to the U. S. Public Health Service.

Bill for Medical Department of the Navy

A bill has been introduced by Congressman George Darrow of Pennsylvania to increase the efficiency of the Medical Department of the Navy. The President, authorized to appoint officers in the Hospital Corps of the Navy, in addition to chief pharmacists and pharmacists, at the rate of one for each 2,000 officers and enlisted men in the Navy and Marine Corps. The ranks are to be lieutenant commander, lieutenant, junior grade, and ensign. They are to perform such duties in the Hospital Corps as may be prescribed by the Secretary of the Navy.

Army Rank for Nurses

The bill to grant army rank for nurses in the army service, in which thousands of nurses throughout the country are interested, has been introduced in the House of Representatives by Representative Hernandez of New Mexico and referred to the House Committee on Military Affairs, of which Julius Kahn of California, is chairman. The measure provides: "that the members of the Army Nurse Corps shall have relative rank as follows: The superintendent shall have the relative rank of major; the assistant superintendents, directors and assistant directors the relative rank of captain; chief nurses the relative rank of first lieutenant; and nurses, the relative rank of second lieutenant; and as regards medical and sanitary matters and all other work within the line of their professional duties shall have and shall be regarded as having authority in and about military hospitals next after the medical officers of the Army, and shall wear the insignia of the rank of the Army to which their rank corresponds."

Sites for Military Hospitals

A report on the selection and acquisition of sites for military hospitals has just been submitted to the United States Senate by a special committee appointed some time ago to make an investigation and recommendations. The committee was directed to "investigate the selection and acquisition of sites for military hospitals, and contracts and expenditures for the repair, acquisition and construction of such hospitals and ascertain what additional hospitals facilities are required." It is officially reported that the Naval hospitals have a total capacity of 15,000 beds, while the Army has a total bed capacity of 110,000 beds. Almost one half of the beds of the Army are unused and will be turned over to the Public Health Service which is charged with the administration of the War Risk Insurance Act in the work of caring for and giving treatment to the men disabled in the war. About 80,000 discharged soldiers and sailors are entitled to this treatment. In view of this large work, the committee has recommended the erection of a tuberculosis hospital at Dawson Springs, Ky., with a capacity of 500 beds, a gift of a tract of land of 5,000 acres having been made in connection with this site. A new hospital plant at Norfolk, Va., is also recommended because of the war risk obligation and because of the fact that Norfolk has heavy demands for hospital service from men in the merchant marine, being the second largest Atlantic seaport. A hospital in or near Washington, D. C., is also recommended, which district is regarded as having insufficient hospital facilities in view of the demand. The adoption of the Speedway, or Maywood Hospital, near Chicago, also is strongly recommended. No other new sites are approved. Fire-resisting construction is recommended in so far as it is at all possible. An appropriation of $190,000 for an addition to the marine hospital at Staten Island, N. Y., and of $750,000 to remodel and adapt existing hospital facilities in and near New York City are recommended because of the large number of cases in that vicinity. The conversion of some facilities at Hot Springs, Ark., is advised. It is thought that these combined facilities will meet the needs of the reconstruction work of the government. The report is signed by Senators Hardwick, Beckham, Trammell, France and Lenroot and was presented to the Senate, June 2. Had the war continued until 1919, as was officially anticipated, the War Department would not have had sufficient hospital facilities to care for the wounded men, according to the report, but the early end of hostilities saved a large sum to the government by reason of this program.

Weekly Bulletin A. E. F. Gives Interesting Statistics

(May 26, 1919)

The *Weekly Bulletin* of the American Expeditionary Forces for May 26 gives some interesting totals.

1. From June 15, 1917, to Feb. 28, 1919, inclusive, there were 708,335 cases of disease, causing a loss of 8,277,657 days of service.

There were 225,955 cases of traumatism (including all battle casualties), causing a loss of 2,705,588 days of service, or a combined total of 934,290 cases, and a loss of 10,983,245 days of service, or 30,091 years.

2. Of the cases of disease: 90.2 per cent. returned to duty; 6.0 per cent. were invalided home; 3.3 per cent. died in hospital and 0.5 per cent. deserted.

Of the cases of traumatism: 73.8 per cent. returned to duty; 21.1 per cent. were invalided home; 5.7 per cent. died in hospital, and 0.4 per cent. deserted.

3. The average time in hospital for both classes of cases was 11.7 pays per case. Of those reported as deserted many are believed to have left the hospitals to return to the front.

4. Mumps has caused the greatest loss of days from noneffectiveness due to disease. There have been 83,202 cases of mumps, with a loss of 1,000,424 days of service in the A. E. F., from July 1, 1917, to March 31, 1919. There were only forty-three deaths from mumps during that period.

5. The greatest number of deaths from disease of all kinds was due to pneumonia. There were 28,292 cases of pneumonia, causing a loss of 622,424 days of service in the A. E. F., from July 1, 1917, to March 31, 1919, inclusive, with 12,361 deaths.

6. Of all deaths in the A. E. F., 32 per cent., or two in seven, died from disease.

Of total deaths from disease for the period June 15, 1918, to March 31, 1919, inclusive, numbering 17,691, there were: 11,786 deaths from pneumonia, or 66.6 per cent.; 715 deaths from meningitis, or 4.0 per cent.; 515 deaths from influenza, or 2.9 per cent.; 351 deaths from tuberculosis, or 1.4 per cent.; 143 deaths from typhoid and paratyphoid, or 0.8 per cent.; 64 deaths from measles, or 0.3 per cent.; 40 deaths from diphtheria, or 0.2 per cent.; 29 deaths from dysentery, or 0.16 per cent.; 27 deaths from scarlet fever, or 0.15 per cent., and 4,021 deaths from all other diseases, or 22.7 per cent. Of all wounded 1 in 14 died.

7. The average rate of venereal diseases was under 40 per thousand per year.

8. Total mental diseases, including mental deficiency, from June 15, 1917, to April 27, 1919, were 12,266 cases of which 8,076 were returned to duty.

9. Total number of cases evacuated from the front 214,487. Total number of patients evacuated to the United States to April 22, 1919, 119,974.

10. Maximum number of beds with date was 299,835 beds on Nov. 21, 1918. (Including convalescent camps, but not evacuation hospitals or other Army units) S. O. S. only.

Maximum number of patients with date was 193,026 on Nov. 12, 1918. (Including convalescent camps). S. O. S. only.

11. The maximum number of hospital centers was twenty-three on Dec. 5, 1918.

12. The maximum number of base hospitals operating at one time was 122 on Jan 2, 1919.

13. The maximum number of camp hospitals operating at one time were sixty-four, on Feb. 6, 1919.

14. The maximum number of convalescent camps was fourteen.

15. Total number of camp hospitals operated during entire period was ninety-seven.

16. Losses in A. E. F., June 15, 1917, to April 15, 1919, inclusive: killed in action, Army and Marines, 33,827; died of wounds, 14,190; wounded, 201,230; died of disease, 22,986; died of other causes, 4,281.

17. Among the medical supplies received by the A. E. F. were: ether, 913,480 pounds, sheets, 3,790,268; foot powder (talcum), 3,024,029 pounds, equal to 1,512 tons; gauze, 107,055,986 yards, equal to 61,338 miles. Unrolled it would extend nearly two and a half times round the would.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

Owing to a change in the plan of sending this material from the Surgeon-General's Office to The Journal, no discharges are available for publication this week. Publication of this list will be resumed next week.

ORDERS TO OFFICERS OF THE MEDICAL CORPS, U. S. ARMY

Alabama

To Camp Bowie, Texas, from Camp Sherman, Lieut. J. H. WINN, Huntsville.

To report to the commanding general, Southern Department, from Camp Shelby, Capt. W. W. LONG, Fayette.

California

To Camp Bowie, Texas, from Camp Kearney, Major C. E. SISSON, Norwalk.

To Camp Kearney, Calif., from San Francisco, Col. E. B. FRICK,

To Fort Sheridan, Ill., from Camp Shelby, Lieut. O. P. STOWE, Mill Valley.

To report to the commanding general, American Expeditionary Forces, from Camp Kearney, Lieut.-Col. H. P. CARTER. Western Department, from Camp Dix, Major V. H. HULEN, San Francisco.

To Walter Reed General Hospital, D. C., from San Francisco, Major A. J. CANNING.

District of Columbia

To Biltmore, N. C., from Fort Oglethorpe, Lieut. E. S. GREEN, Washington.

To Fort Jay, N. Y., from Surgeon-General's Office, Col. E. A. DEAN.

To San Francisco, Calif., Letterman General Hospital, from Army Medical School, Lieut. A. L. GUERRA, Washington; from Walter Reed General Hospital, Col. R. REYNOLDS.

Florida

To Baltimore, Md., from Atlanta, Capt. J. F. WILSON, Lakeland.

Georgia

To Camp Bowie, Texas, from Fort Oglethorpe, Capt. W. A. WILLIAMS, Monticello.

To Camp Bragg, N. C., from Camp Dix, Lieut. J. R. TURNER, Temple.

To Camp Zachary Taylor, Ky., from Camp Dix, Lieut. J. M. TRIBBLE, Senoia.

Illinois

To Army Medical School for instruction, from Camp Lee, Lieut. C. B. HERRMANN, Chicago.

To Camp Bowie, Texas, from Camp Custer, Lieut. G. B. MATHISEN, Chicago; from Camp Jackson, Capt. J. K. POLLOCK, Elgin.

To Camp Sherman, Ohio, base hospital, from Camp Shelby, Capt. F. G. MORRILL, Havana.

To Cape May, N. J., from San Francisco, Capt. W. H. GALLAND, Chicago.

To Fort Des Moines, Iowa, from Camp Gordon, Lieut. J. R. SHOLL, Peoria.

To Fort Sheridan, Ill., from Camp Dix, Major C. R. FORRESTER, Chicago.

To Fort Snelling, Minn., from Camp Dix, Capt. H. J. WYCKOFF, Chicago.

To report to the commanding general, Central Department, from Camp Grant, Major W. D. BOER, Chicago.

To St. Louis, Mo., from Camp Grant, Lieut. E. L. DALLWIG, Chicago.

The following order has been revoked: *To Detroit, Mich.,* from Camp Custer, Capt. J. W. CLARK, Chicago.

Indiana

To Camp Bowie, Texas, from Camp Custer, Capt. C. A. UNDERWOOD, Indianapolis.

To Detroit, Mich., from Camp Zachary Taylor, Capt. L. H. REDMAN, Elizabethtown.

To Jefferson Barracks, Mo., from St. Louis, Major G. W. NEWELL, Peru.

To report to the commanding general, Central Department, from Camp Dix, Capt. H. W. NIMAL, Indianapolis.

Iowa

To Camp Bowie, Texas, to examine the command for cardiovascular disease, from Camp Jackson, Lieut. A. C. DAVIS, Iowa City.

To Colonia, N. J., from Fox Hills, Capt. E. J. LAMBERT, Ottumwa.

To Fort Clark, Texas, from Fort Benjamin Harrison, Lieut. C. KAIL, Stratford.

To Hampton, Va., f [illegible] Major L. D. CRUICE.

To report to the [illegible] Central Department, from Camp Dix, Lieut. J. [illegible] GUTHRIE, Rockwell.

Kansas

To Walter Reed General Hospital, D. C., from Fort Riley, Capt. M. R. JOHNSTON.

Kentucky

To Camp Shelby, Miss., base hospital, from Fort Snelling, Lieut. D. B. ROACH, Cadiz.

To Camp Zachary Taylor, Ky., from Camp Dix, Capts. A. L. SOLOMON, Hodgenville; E. L. HENDERSON, Louisville.

To Fort Benjamin Harrison, from Camp Abraham Eustis, Capt. E. MOORMAN, Harned.

To Washington, D. C., Surgeon-General's Office, from Camp Meade, Major C. E. CLAYTON, Dexter.

Maine

To Plattsburg Barracks, N. Y., from Camp Devens, Capt. W. B. MOULTON, Portland.

To report to the commanding general Hawaiian Department, from Fort Riley, Major B. F. HAYDEN, South Portland. Southern Department, from Scituate, Mass., Lieut. W. E. GOULD, Livermore.

To Washington, D. C., Surgeon-General's Office, from Camp Dix, Major A. U. DESJARDINS, Waterville.

Maryland

To Boston, Mass., from Fort McHenry, Col. W. A. POWELL.

To Washington, D. C., Surgeon-General's Office, from Camp Dix, Lieut. A. W. REIER, Glenarm.

To Whipple Barracks, Ariz., from Fort McHenry, Capt. M. B. LEVIN, Baltimore.

Massachusetts

To Camp Bowie, Texas, from Army Medical School, Lieut. E. J. FITZGIBBON, Boston.

To Camp Shelby, Miss., base hospital, from Camp Devens, Capt. J. A. LYON, Rutland.

To Camp Sherman, Ohio, base hospital, from Camp Jackson, Lieut. J. L. DOWLING, Boston.

To Plattsburg Barracks, N. Y., from Fort Des Moines, Lieut. F. L. FORAN, Worcester; from Lakewood, Lieut. R. C. JONES, Fitchburg.

To report to the commanding general, American Expeditionary Forces, from Boston, Col. J. T. CLARKE. Eastern Department, from Camp Dix, Major E. A. KNOWLES, Medford; Capt. J. F. BOWEN, Amherst. Northeastern Department, from Camp Devens, Lieut. T. W. ELY, Boston; from Camp Dix, Lieut. S. B. ANNIS, Natick.

Michigan

To Camp Bowie, Texas, from Camp Travis, Lieut. L. M. BUSH, Detroit.

To Camp Custer, from Camp Dix, Major R. G. LELAND, Kalamazoo, from Camp Dodge, Major W. N. SALISBURY, Ann Arbor.

To Carlisle, Pa., from Camp Custer, Capt. C. A. BERGE, Ann Arbor.

To Hoboken, N. J., from Camp Custer, Major A. E. LEMON, Detroit.

To Plattsburg Barracks, N. Y., from Fort Des Moines, Lieut. G. H. CAMPAU, Detroit.

Minnesota

To Camp Dodge, Iowa, from Camp Dix, Capt. S. B. MAXEINER, Minneapolis.

To Fort Snelling, Minn., from Camp Dix, Capt. I. F. SELLESETH, Glenwood.

Mississippi

To Camp Pike, Ark., from Camp Dix, Capt. J. C. ARMSTRONG, Water Valley.

To Colonia, N. J., from Fort Oglethorpe, Capt. J. T. HOSEY, Enterprise.

Missouri

To Camp Grant, Ill., base hospital, from Camp Dix, Major D. E. SINGLETON, Clarence.

To Fort Riley, base hospital, from Camp Dix, Major L. H. WINEMILLER, Farley.

Montana

To Fort McHenry, Md., from Baltimore, Lieut J. R. McDOWELL, Intake.

To San Francisco, Calif., Letterman General Hospital, from Camp Kearney, Capt. A. A. HUSSER, Hingham.

Nebraska

To Camp Meade, M.D., from Fort Crockett, Capt. J. M. WOODARD, Aurora.

New Hampshire

To report to the commanding general, Northeastern Department, from Boston, Major J. A. DREW, Rumney.

To Spartanburg, S. C., from Denver, Capt. J. C. THOMPSON, North Stratford.

New Jersey

To Camp Dix, N. J., base hospital, from Hoboken, Capt. J. B. WINTERSTEEN, Moorestown.

To Colonia, N. J., from Lakewood, Lieut. J. J. BURNE, Newark.

To Fort Monroe, Va., from Lakewood, Col. C. F. MASON.

To report to the commanding general, American Expeditionary Forces, from Lakewood, Major C. H. GODDARD.

To San Francisco, Calif., from Hoboken, Col. G. L. EDIE.

To Walter Reed General Hospital, D. C., from Camp Dix, Cols. A. S. BOWEN, R. E. GOLDTHWAITE, R. REYNOLDS, G. V. RUKKE, Majors P. E. McNABB, H. E. WEBB, Capt. E. B. SPAETH; from Hoboken, Col. R. M. THORNBURGH.

To Washington, D. C., Surgeon-General's Office, from Camp Dix, Col. E. A. DEAN.

New Mexico

To Whipple Barracks, Ariz., from Camp Kearney, Major H. B. KAUFFMANN, Albuquerque.

New York

To Camp Bowie, Texas, from Camp Shelby, Lieut. E. E. VAN DERWERKER, New York; from Camp Travis, Lieut. E. CALVELLI, New York.

To Camp Dix, N. J., to examine the command for cardiovascular disease, from Camp Meade, Lieut. D. SCHULTHEIS, New York.

To Camp Dodge, Iowa, from Fort Des Moines, Lieut. L. HAUSMAN, New York.

To Carlisle, Pa., from Detroit, Capt. H. A. GRIFFIN, New York.

To Fort Hamilton, N. Y., from Fort Schuyler, Major S. S. PIPER, Elmira.

To Fort Porter, N. Y., from Plattsburg Barracks, Capt. G. C. FISK, Buffalo.

To Fort Riley, base hospital, from Camp Dodge, Major H. A. DURHAM, New York.

To Fort Schuyler, N. Y., from Camp Dix, Major D. B. BRINSMADE, New York.

To Hampton, Va., from Camp Dix, Capt. E. N. BOUDREAU, Auburn; from Fort Oglethorpe, Capt. J. J. HARRINGTON, New York.

To Hoboken, N. J., from Camp Dix, Lieut. J. F. X. LOORAM, Brooklyn.

To Otisville, N. Y., from Oteen, Lieut. H. J. SEIFF, New York.

To Plattsburg Barracks, N. Y., from Hoboken, Major J. H. CARROLL, New York; from Lakewood, Lieut. B. J. SLATER, Rochester; from Walter Reed General Hospital, Lieut. J. HARKAVY, New York.

To report to the commanding general, Eastern Department, from Fort Sam Houston, Major L. M. SIMONSON, Pelham.

To San Francisco, Calif., Letterman General Hospital, from Camp Dix, Capt. O. E. UTZINGER, Ithaca.

To Spartanburg, S. C., from Camp Jackson, Lieut. C. M. MANN, Petersburg; from Camp Meade, Lieut. M. A. McIVER, New York.

To Washington, D. C., Surgeon-General's Office, from Camp Dix, Major J. R. OLIVER, New York.

The following order has been revoked: *To Spartanburg, S. C.*, from Plattsburg Barracks, Capt. W. A. SHAW.

North Carolina

To report to the commanding general, Southern Department, from Camp Sevier, Lieut. R. S. McGEACHY, Raleigh.

To Spartanburg, S. C., from Camp Devens, Lieut. J. E. COCKE, Asheville.

North Dakota

To Fort Snelling, Minn., from Fort McHenry, Lieut. R. L. GHERING, Larimore.

Ohio

To Camp Bowie, Texas, from Camp Sherman, Lieut. A. A. BRINDLEY, Port Clinton.

To Camp Kearney, Calif., from Toledo, Lieut.-Col. G. H. McLELLAN.

To Fort Sheridan, Ill., from Camp Dix, Capt. J. C. GEORGE, Dayton; from Camp Grant, Lieut. M. H. SHIPLEY, Cleveland.

To Oteen, N. C., from Camp Custer, Capt. H. H. WARD, Cleveland.

To report to the commanding general, Central Department, from Camp Dix, Lieut. J. L. BEACH, Seville.

To Washington, D. C., from Camp Dix, Major N. P. McGAY, Cleveland.

Oklahoma

To Army Medical School for instruction, from Fort Des Moines, Lieut. J. E. HEATLEY, Carmen.

To Fox Hills, N. Y., from Camp Pike, Capt. W. W. WOODY, Tulsa.

Pennsylvania

To Camp Bowie, Texas, from Camp Sherman, Lieut. J. C. FULMER, Williamsport.

To Camp Meade, Md., from Army Medical School, Capt. W. F. BEITSCH, New Brighton.

To Camp Sherman, Ohio, from Camp Dix, Capt. M. S. BOWERS, Braddock.

To Fort Sam Houston, Texas, base hospital, from Camp Sherman, Capt. I. L. OHLMAN, Pittsburgh.

To Fort Totten, N. Y., from Camp Dix, Major N. D. SMITH, Rutledge.

To Fort Washington, Md., from Camp Dix, Capt. R. E. THOMAS, Scranton.

To Philadelphia, Pa., from Surgeon-General's Office, Major W. WALKER, Philadelphia.

To Pittsburgh, Pa., from Camp Dix, Capt. J. H. ALEXANDER, Pittsburgh; from Lakewood, Capt. W. P. HUGHES, Pittsburgh.

To report to the commanding general, Northeastern Department, from Camp Dix, Capts. R. S. K. HANIGAN, East Prospect; C. J. WATSON, Philadelphia; from Fort Oglethorpe, Lieut. W. L. COLEMAN, Easton.

Rhode Island

To Key West Barracks, Fla., from Camp Zachary Taylor, Capt. R. S. WILCOX, Providence.

South Carolina

To Fort Riley, base hospital, from Fort Des Moines, Major G. G. COTTAM, Sioux Falls.

To Spartanburg, S. C., from Camp Jackson, Major E. C. MAJOR, Latta.

Texas

To Camp Bowie, Texas, to examine the command for cardiovascular disease, from Camp Meade, Lieut. E. TOOMIN, Waco.

To Denver, Colo., from Fort Sam Houston, Capt. L. L. HEWLETT, Lockhart.

To Fort Bayard, N. M., from Camp Bowie, Lieut. C. H. BROOKS, Waco.

To Fort Worth, Texas, from Camp Dix, Lieut. F. H. NEWTON, Dallas.

To Fox Hills, N. Y., from Camp Dix, Major C. C. CODY, Jr., Houston.

To report to the commanding general, Southern Department, from Camp Dix, Capt. J. C. McKEAN, Lometa; from Fort Oglethorpe, Lieut. W. N. LIPSCOMB, Crockett.

Virginia

To Camp Meade, Md., from Carlisle, Major P. C. RILEY, Markham.

To Denver, Colo., from Newport News, Col. H. H. JOHNSON.

To Fort Leavenworth, Kan., from Newport News, Col. M. A. W. SHOCKLEY.

To Fort Riley, base hospital, from Camp Dodge, Capt. C. M. EDWARDS, Richmond.

To Plattsburg Barracks, N. Y., from Camp Dix, Capt. S. T. NOLAND, Leesburg; from Camp Meade, Lieut. R. A. MOORE, Phenix.

West Virginia

To Camp Zachary Taylor, Ky., from Camp Dix, Capt. W. B. ROBERTSON, Quincy.

Wisconsin

To Camp Bowie, Texas, from Camp Sherman, Capt. J. W. LOCKHART, Oshkosh; Lieut. E. A. GATTERDAM, Wauwatosa.

To Oteen, N. C., from Biltmore, Capt. A. O. SANDERS, Superior.

Wyoming

To San Francisco, Calif., Letterman General Hospital, from Fort Rosecrans, Capt. O. K. SNYDER, Cheyenne.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Personal.—Charles A. Robinson, formerly attending physician at the California State Reform School for Boys, has been appointed health officer for Madera city and county.

Anesthetists Organize.—May 6, the anesthetists of southern California organized a society to be known as the Southern California Society of Anesthetists, whose objects are primarily scientific, and secondarily the securing of such state legislation as shall debar the "anesthetic technician" from a legitimate medical field. Dr. Frank D. Bullard, Los Angeles, was elected president, and Dr. Eleanor C. Seymour, Los Angeles, secretary-treasurer.

ILLINOIS

Hospital News.—An addition to the Lutheran Hospital, Moline, is to be built this summer at a cost of $65,000. With this addition the institution will have a capacity of 125 beds. ——The city council of Belvidere has appropriated $2,000 toward the new hospital to be erected in that city.

Personal.—Bellenden S. Hutcheson, Mound City, Capt., M. C., U. S. Army, who has been on duty in France and who won the Victoria Cross and British Military Cross, arrived home, June 6.——Dr. John C. Ellis, Decatur, is said to have pleaded guilty to a charge of violation of the Harrison Narcotic Law and to have been fined $300 and costs, June 3.——A suit for damages for $25,000 has been filed against Drs. Robert L. French and William L. Ruggles, Oak Park, by Capt. Harry B. Todd, Oak Park.

Chicago

Illegal Practitioner Arrested.—William James, 2938 South Dearborn Street, was arrested by the Department of Registration and Education of the State of Illinois for practicing medicine without a license. James was found guilty, but on account of his advanced years, he was placed on parole for one year.

Rush Alumni Elect Officers.—At the annual meeting of the Alumni Association of Rush Medical College the following officers were elected: president, Dean D. Lewis, Col., M. C., U. S. Army; secretary, Dr. Charles A. Parker; treasurer, Dr. Elmer L. Kenyon; directors for three years, Drs. George H. Coleman and B. McPherson Linnell.

Establishment of John M. Dodson Lecture.—At the annual meeting of the Alumni Association of Rush Medical College, held in Chicago, June 6, Dr. John M. Dodson was presented with a gold watch as an appreciation of his thirty years of service to the college. The Alumni Association also established the John M. Dodson Lecture to be delivered in connection with the work of the Rush Postgraduate School of Medicine of the University of Chicago. The lecture is to be on medical education, history or on any other subject relative to the advance of medical science. The choice of lecturer and subject is vested in a self-perpetuating committee consisting of Dr. Ludvig Hektoen, chairman, Drs. George H. Coleman, Morris Fishbein, Elmer L. Kenyon and John E. Rhodes. The presentation address and the announcement of the lecture fund were made by Dr. Arthur Dean Bevan.

Hospital News.—Taylor E. Darby, Lieut.-Col., M. C., U. S. Army, in command of U. S. Army General Hospital No. 32, has received orders to vacate the building, June 15, and evacuate the soldiers now quartered there to U. S. Army General Hospital No. 28, Fort Sheridan, Ill.——Plans have been announced for a maternity hospital to be established at Forty-Seventh Street and California Avenue, to be called the Misericordia Hospital, and to cost $100,000.——Plans for the resumption of the preliminary work for the new medical college and hospital buildings for the University of Chicago have again been taken up. The new medical school will be constructed on the property owned by the university on the south side of the midway, and the first building to be erected will be a hospital and dispensary to cost $1,000,000. The school for practitioners will be located near Rush Medical College, and the hospital will be known as the Albert Merritt Billings Hospital. The buildings planned will cost $17,000,000.

INDIANA

Antituberculosis Association Organized.—The League of Tuberculosis Associations of the Thirteenth District of Indiana, affiliated with the state and national organizations, was organized at Plymouth, May 22. Mr. James Wilkinson, Goshen, was elected chairman; Mrs. Ethel M. Cook, Plymouth, secretary, and Mrs. William B. Siders, Warsaw, treasurer.

Personal.—Henry O. Brueggeman, Lieut.-Col., M. C., U. S. Army, Fort Wayne, who since his return from France has been on duty at Fort McHenry, Md., will soon be released from service.——Dr. Lester I. Ofner, superintendent of the Irene Byron Tuberculosis Hospital on the Allen County Farm, Fort Wayne, has resigned on account of ill health.——Dr. Richard B. Wetherill, Lafayette, announces his retirement, June 1, after thirty-six years of practice of medicine in Lafayette.——Dr. George H. Hoskins, Whiting, has been elected president and Dr. H. E. Graham, Gary, secretary, of the Lake County Anti-Tuberculosis Society.——Dr. Hugh T. Montgomery, South Bend, the oldest living charter member of the St. Joseph County Medical Association, was the guest of honor at the thirty-second anniversary meeting of the organization, May 14.

Venereal Clinics.—The city council of Kokomo has appropriated $1,500 for the establishment and maintenance of a free clinic for the treatment of venereal diseases, and it said that the city council has also enacted an ordinance requiring physicians to report for quarantine or treatment all cases submitted to them.——The city council of Madison has made an appropriation for the beginning of the work against venereal disease in that city.——A free venereal clinic was opened, May 3, at Anderson in charge of Ed C. Davis, Indianapolis.——The Terre Haute Public Health Clinic is in active operation under the charge of Dr. Maurice B. Van Cleave.——A free venereal disease clinic has been organized for Allen County at Fort Wayne in charge of Dr. Gaylard M. Leslie.——A venereal disease clinic for South Bend was opened, June 1, under the charge of M. R. Birmingham, Indianapolis.

IOWA

Personal.—Dr. David O. King, Eldora, has been appointed local surgeon of the Northwestern system.——Dr. George B. Thompson, Winthrop, is reported to be critically ill.——Dr. Walter W. Daut has been elected health physician of Muscatine.——Dr. Sara E. Foulks, Davenport, is now in Serbia with the Balkan mission of the American Red Cross.——Frederick H. Roost, Major, M. C., U. S. Army, Sioux City, has been commissioned lieutenant-colonel, and is now stationed in Luxembourg.——Dr. Charles E. Ruth, Des Moines, who for six months has been commanding officer of the hospital at Fort William McKinley, Manila, P. I., returned home, May 5.

KENTUCKY

State Health Board Moves to Louisville.—The headquarters of the Kentucky State Board of Health, which have been at Bowling Green since 1883, were moved to Louisville, May 1. The new location is in the old Union National Bank Building at Sixth and Main streets.

Sanatorium at Dawson Springs.—Work has been started on the Federal Hospital at Dawson Springs where 5,000 acres in Hopkins and Christian counties have been deeded for this purpose. It is expected that between $12,000,000 and $15,000,000 will eventually be expended on this institution, which will include an administration building, tuberculosis sanatorium, hospital for nervous diseases, general hospital, and building for vocational training.

Personal.—Dr. William E. Gary, head of the milk and food division of the Louisville Health Department, has resigned to accept a position as head of the roentgen-ray and pathologic department of the Jennie Stuart Memorial Hospital, Hopkinsville.——Sidney J. Meyers, Lieut.-Col., M. C., U. S. Army, Louisville, has returned after eight months of service in France, where he was in command of Base Hospital No. 238, Rimancourt.——Dr. Joseph E. Wells, Cynthiana, has been appointed a member of the state board of health.

MARYLAND

Correction.—Capt. Raymond R. Decker, commanding U. S. Army General Hospital No. 7, Roland Park, Baltimore, writes that the Baltimore correspondence appearing in the May 17 issue of The Journal to the effect that the hospital "recently reverted from military to Red Cross control" is incorrect. The Red Cross will conduct a school for the reeducation of war blinded soldiers, sailors and marines, using the temporary buildings on the military reservation heretofore known as U. S. Army General Hospital No. 7, but will have no control over, or affiliation with, that institution. The blind men will be discharged from military service and will attend the school as civilians, or rather as wards of the Federal Board for Vocational Education, which will have as its representative a supervisor of the blind, stationed at the school. The reservation and all property remains under government control and will be guarded and policed by detachments of soldiers after the demobilization of the hospital is completed.

Personal.—Dr. William H. Welch has returned to Baltimore, after spending several months as one of the representatives of the United States at the international convention of the Red Cross, held at Cannes, France.——After serving as professor of gynecology at the Johns Hopkins Hospital for thirty years, Dr. Howard A. Kelly, Baltimore, has resigned. He will be succeeded by Dr. Thomas S. Cullen, who has been assistant professor of gynecology at the Johns Hopkins Hospital for a number of years. Dr. Kelly gave as his reasons for taking this step that he had held the position long enough and that he would be free to give more attention to his profession along other lines, as well as to his other activities.——Dr. Frank C. Marino, Baltimore, who served with the Medical Corps in France and was in front-line hospitals at Château Thierry, St. Mihiel and Verdun, has been appointed medical superintendent of St. Joseph's Hospital, Baltimore.——Andrew C. Gillis, Lieut.-Col., M. C., U. S. Army, former superintendent of Mercy Hospital, Baltimore, who was in charge of a group of hospitals in the Toul sector, has returned from overseas and is now at his home in Baltimore.——Dr. Arthur Wegefarth, Baltimore, has been confined to his home with a severe attack of tonsillitis, followed by mumps.

MASSACHUSETTS

Harvard Alumni Meeting.—The annual meeting of the Harvard Medical Alumni Association will be held in Harvard Hall, Cambridge, on Commencement Day, June 19, at 12:30 p. m.

Personal.—Dr. Joseph P. Mulhern, Boston, has been appointed resident physician of the Long Island Hospital.——Dr. Clement C. Nevin, Edgartown, has been appointed associate medical examiner (coroner) for Dukes County, succeeding Dr. Orland S. Mayhew, Tisbury.

State Society Elects Officers.—The Massachusetts Medical Society held its one hundred and thirty-eighth annual meeting in Boston, June 3 and 4, under the presidency of Dr. Samuel B. Woodward, Worcester, and the following officers were elected: president, Dr. Alfred Worcester, Waltham; vice-president, Dr. Arthur R. Crandell, Taunton; secretary, Dr. Walter L. Burrage, Jamaica Plains (reelected); treasurer, Dr. Arthur K. Stone, Framingham Center; librarian, Dr. Edwin H. Brigham, Brookline, and orator, Dr. Hugh Cabot, Boston.

MICHIGAN

Nurses Memorial Home.—James Couzens, mayor of Detroit, announces that he will present the city with a nurses' home in memory of the Detroit nurses who served during the world war. The building will be six stories in height, 114 by 147 feet, and will cost $300,000.

Health Officers Organize.—The Michigan chapter of the American Public Health Association was organized at the annual convention of the Michigan State Medical Society, and the following officers were elected: chairman, Dr. Richard M. Olin, Lansing, state health commissioner; secretary-treasurer, Dr. Victor C. Vaughan, Ann Arbor. A board of directors was appointed by Dr. Richard M. Olin, state health commissioner and chairman of the board, as follows: Drs. Guy L. Kiefer, Detroit; William De Kleine, Flint; Neagle, Jackson; Clyde C. Slemons, Grand Rapids; Alvin H. Rockwell, Kalamazoo; Charles P. Drury, Marquette; Joseph J. Gerkins, Ironwood; Charles A. Neafle, Pontiac; Eugene Miller, Battle Creek; William G. Wright, Lansing; Arthur F. Fischer, Hancock, and George A. Holliday, Traverse City; Mrs. Lystra E. Gretter and Paul Rachel, Detroit; Profs. W. C. Hoad and Warren E. Forsythe, Ann Arbor; Mr. Shoecraft, city engineer of Flint, and W. S. Spery, Grand Rapids.

MISSOURI

Personal.—Dr. Thomas B. M. Craig, Nevada, has been appointed superintendent of the State Hospital No. 3, Nevada, succeeding Dr. William P. Bradley, resigned.—— Dr. Joseph R. Hamer, Cameron, has been oppointed coroner for Clinton County.

State Association Meeting.—The Missouri State Medical Association held its sixty-second annual meeting at Excel- sior Springs, May 26 to 28, with an attendance of 434. The following officers were elected: president, Dr. Nimrod P. Wood, Independence; vice presidents, Drs. John J. Gaines, Excelsior Springs; Edwin F. Yancey, Sedalia; William A. Clark, Jefferson City; Arthur M. Gregg, Joplin, and J. Curtis Lyter, St. Louis; secretary, Edward J. Goodwin, St. Louis (reelected); treasurer, J. Franklin Welch, Salisbury; and councilors: fifteenth district, Linn J. Schofield, Warrensburg; twenty-second district, Henry L. Reid, Charleston; twenty- sixth district, William H. Breuer, St. James; twenty-seventh district, James C. B. Davis, Willow Springs; twenty- eighth district, Arthur L. Anderson, Springfield, and twenty- ninth district, Robert L. Wills, Neosho. The next meeting will be held at Jefferson City.

NEBRASKA

Personal.—Dr. Moth has been elected city physician of Omaha, succeeding Dr. Harry D. Kelly, resigned.——Alvah Sherman Pinto, Major, M. C., U. S. Army, Omaha, command- ing Base Hospital No. 48, Recey, France, has been made lieutenant-colonel, Medical Corps.

Medical School Now Registered.—A letter from the dean of the University of Nebraska College of Medicine states that that college was admitted to the list of registered institutions by the board of regents of the University of the State of New York at a meeting, held May 29.

Physicians' Building in Omaha.—The Medical Building Association has been incorporated in Omaha with a capital of $1,500,000 with the object of building and operating a twenty-story building at Seventeenth and Dodge streets, Omaha. The officers of the association are: Dr. William P. Wherry, president; Dr. W. H. Sherraden, vice president; Dr. Ernest W. Powell, secretary, and Mr. Leonard W. Scheibel, treasurer.

NEW YORK

Personal.—Dr. Frederick D. Keppel, third assistant secretary of war and former dean of Columbia University, will become director of the foreign operations of the American Red Cross, July 1.

New York City

Columbia University.—At the commencement of Columbia University, June 5, the degree of Doctor of Medicine was conferred on 138 graduates. The biennial Cartwright prize of the School of Medicine, of $500, was awarded to Dr. Abraham Leon Garbat of New York City.

Alumni Elect Officers.—At the annual meeting of the Society of the Alumni of City (Charity) Hospital, held May 21, the following officers were elected: president, Dr. Charles Ogilvy; vice president, Dr. Walter Seymour Reynolds; secretary, Dr. Wm. M. Patterson, and treasurer, Dr. Perry Bartlette Hough, all of New York City.

Memorial Hospitals to Be Established.—In memory of 120 men from the fourth ward of Brooklyn, who lost their lives in the war, a campaign is being planned to raise a fund of $500,000 to be equally divided between the Jamaica Hospital and St. Mary's Hospital to be used for the erection of much needed additions to these institutions. The extension is to be decorated as a memorial to the soldiers of the fourth ward.

Personal.—Dr. Alexandra Acha, Peruvian delegate to the American Medical Association, and Dr. Cary Eggleston of New York, while on their way to West Point, a trip which was a part of the entertainment of foreign delegates to the meeting of the American Medical Association, were the victims of an automobile accident. They were taken to the hospital at Tuxedo. Fortunately neither of them sustained serious injuries.

Plan to Make Brooklyn Medical Center.—A number of the leading physicians of Brooklyn met at the Hamilton Club, June 2, to discuss the possibilities of developing Brooklyn's resources as a teaching center. The meeting was presided over by Dr. Glentworth R. Butler. Others interested in the project are Drs. H. Beeckman Delatour, Brooklyn, John A. Lee, Otto V. Huffman, Lewis S. Pilcher, Joshua M. Van Cott, Edwin H. Fiske, William Browning, William B. Brinsmade and Jacob Fuhs.

Columbia University Plans New System of Physical Education.—Under the direction of Dean Herbert E. Hawkes, Dr. W. H. Castline, and Dr. George L. Meylan a new system of physical education for the development of the health and physical condition of college students has been perfected and will be begun at the opening of the fall term. Medical sur- veillance will be extended to the student from the day he enters college until he receives his diploma. When physical defects appear they will be corrected, with the purpose of turning out 100 per cent. men physically as well as mentally. Plans have also been made for caring for students who show conditions of malnutrition, underweight, etc. The university restaurant has been placed under the direction of Prof. Charles T. MacFarline and students will be supplied with good food properly balanced and special diets will be fur- nished. In order to carry out these plans the university plans to maintain on the campus a staff of physicians and nurses.

PENNSYLVANIA

Personal.—Dr. James F. Edwards, for many years director of the department of health at Pittsburgh, has been appointed health commissioner of Omaha.——Dr. Andrew R. Cancel- liere, Pittsburgh, who suffered a fracture of the skull in an automobile accident, May 18, is reported to be improving. ——Dr. Walter A. Dearth, Pittsburgh, has been elected a member of the Allegheny County Prison Board.

Dixon Memorial.—A bronze tablet, in memory of the late Dr. Samuel G. Dixon, state commissioner of health from the creation of the department of health until his death last year, was unveiled at the State Tuberculosis Sanitarium at Ham- burg, Berks County, June 6. The tablet was presented by the patients at the institution as a memorial to the official who took such an interest in their welfare and was affixed to a large boulder in the ground.

Philadelphia

Medical Society Reception.—The Medical Club of Phila- delphia held its last reception of the season at the Bellevue- Stratford Hotel, June 18. The Honorable Robert L. Owen, United States senator from Oklahoma, and the foreign dele- gates of the American Medical Association were the guests of honor.

Babies' Hospital.—The building for the Babies' Hospital of Philadelphia, which was planned previous to the war, will now be built as planned at the Northeast Corner of Seventh and Delancey Streets and will cost $110,000. The building will be on a lot 40 x 81 feet, and will be six stories in height and of colonial type.

Commencement at Jefferson.—At the ninety-fourth annual commencement exercises at Jefferson Medical College, June 7, a class of 142 was graduated. The degree of doctor of laws was conferred on Major-Gen. Merritte W. Ireland, Surgeon-General, U. S. Army, and Vice-Admiral Grieve. General Ireland, in his address, lauded the company of soldiers who submitted themselves as volunteers for experiments with disease-bearing lice to determine the cause of trench fever.

Personal.—Lieut.-Col. Clarence P. Franklin, M. C., U. S. Army, was the guest of honor at a banquet at the Hotel Walton, given June 5, by prominent members of the Italian Colony of this city.——Daniel M. Hoyt, Lieut.-Col., M. C., U. S. Army, commander of Base Hospital No. 55, has returned to Camp Merritt, N. J., where he is awaiting demobilization.——At the annual meeting of the Philadelphia Laryngological Society, June 3, Dr. J. Solis-Cohen was elected honorary president for the term of his life.

SOUTH DAKOTA

New State Officers.—At the thirty-eighth annual meeting of the South Dakota State Medical Association held in Watertown, May 20 to 22, under the presidency of Dr. Daniel L. Scanlan, Volga, Sioux Falls was selected as the place of meeting for 1920 and the following officers were elected: president, Dr. Robert D. Alway, Aberdeen; vice presidents, Drs. Harry T. Kenney, Pierre, and George S. Adams, Yankton, and secretary-treasurer, Dr. Frederick A. Spafford, Flandreau.

VERMONT

Board of Health in New Quarters.—The state board of health has moved to its new home at 2 Colchester Avenue. The building contains twenty-two rooms and has special quarters for officers of the board and state laboratory.

Personal.—Dr. Edgar O. Crossman, medical superintendent of the Lakeview Sanatorium, Burlington, has opened an office in Manchester, N. H.——Dr. Charlotte Fairbanks, St. Johnsbury, has been made a "Citizen of France," and has received from the mayor of Luzancy a gold medal in appreciation of her services as surgeon in the medical unit of the American Women's Hospital in France.

WEST VIRGINIA

State Society Meeting.—At the fifty-second annual meeting of the West Virginia State Medical Association held in Clarksburg, May 20 to 22, under the presidency of Dr. Robert J. Reed, Wheeling, Parkersburg was selected as the next place of meeting, and the following officers were elected: president, Dr. Henry R. Johnson, Fairmont; vice presidents, Drs. Benjamin F. Shuttleworth, Clarksburg, Walter E. Vest, Huntington, and Joseph L. Miller, Thomas; secretary, Dr. J. Howard Anderson, Marytown (reelected); treasurer, Dr. Hugh G. Nicholson, Charleston (reelected); delegate to the American Medical Association, Dr. Henri P. Linsz, Wheeling, and alternate, Dr. John E. Cannaday, Charleston.

WISCONSIN

Morphin Addict Robs Physician's Offices.—We are informed by Dr. Oscar N. Mortensen of Grand Rapids, that, June 4, a morphin habitué broke into his office and took some Liberty Bonds. He had called at the office and asked for drugs. The man is described as a typical drug addict—sallow, with several large sores on the face, dark hair, about 30 years old and about 5 feet, 10 inches tall.

New Hospitals.—A third Catholic hospital is to be established in Superior by the Sisters of St. Joseph who have acquired as a site the William Patterson Home on Bay Street. ——The new medical buildings on the campus of the University of Wisconsin, Madison, are to be known as the Bradley Memorial Hospital and University Infirmary. They will be ready for occupancy by July 1.——A central city dispensary is to be established at De Pere in the Parmentier Building.

CANADA

Personal.—Lieut.-Col. F. McKelvey Bell, Ottawa, Ont., director of medical services for the Canadian Department of Soldiers' Civil Reestablishment, has resigned. He states in his letter of resignation that the medical branch of this department has been made secondary in importance to almost every other branch in the organization, and that many important recommendations he made have never been acceded to. Lieutenant-Colonel Bell was in charge of the medical services at Halifax at the time disaster overwhelmed that city. ——Dr. Edwin G. Hodgson, Toronto, has returned from overseas.——Prof. Alexander McPhedran, Toronto, and Principal Hibben of Princeton University, were given the honorary degree of doctor of laws at the recent convocation of the University of Toronto. Among others who received honorary degrees were: Robert Russell Bensley, Chicago (doctor of science), and Frank Rattray Lille of the University of Chicago.

University News.—Announcement has been made of the following bequests to the University of Toronto: $50,000 by the will of the late Dr. Julius Mickle, London, England, a former graduate of the university. This amount to be divided into two fellowships, one in honor of the father of the donor and the other to honor the mother. The former is to consist of the proceeds of $25,000 and is to be awarded to the person who, during the preceding ten years, had done most to promote the sound practice of medicine, and this will be open to all the world. The other fellowship will be awarded to the student of the University of Toronto who passes highest in his or her third and fourth years.——An unnamed donor has given the University of Toronto $10,000 through Mrs. McCrae Kilgour, Brandon, Man., to perpetuate the memory of her brother, the late Col. John McCrae, who was an alumnus of the university. This will be used for two scholarships to be given alternate years to students from Guelph Collegiate Institute; failing one, then from any other institute in Canada.——The residue of the estate of the late Dr. Richard A. Reeve, Toronto, goes to the University of Toronto, but the amount is not definitely known as yet.—— The president of the University of Toronto has asked all members of the clinical medical department to place their resignations in the hands of the newly appointed professor of medicine, Dr. Duncan A. L. Graham. It is understood there are to be a number of changes. Dr. Graham will strive to bring about the more intimate correlation of laboratory and clinical methods for diagnosis and treatment of disease. It is likely that each ward of the general hospital will have a small laboratory in charge of a pathologist.

LATIN AMERICA

Deaths in the Profession.—Dr. **Miguel Ochoa** of Buenos Aires, where he had a private medical clinic in addition to his work in the public hospitals.——Dr. **Romualdo Ibañez,** formerly of the editorial staff of the *Crónica Médica* of Lima, Peru.

Inauguration of Radium Institute at Rio de Janeiro.—The Instituto de Radiologia da Faculdade de Medicina was recently inaugurated with much ceremony, Prof. Aloysio de Castro presiding. The radium treatment department is in charge of Profs. F. Terra and E. Rabello, while the roentgen department continues in charge of the chiefs for many years, of roentgen work, Drs. R. Duque Estrada and A. Machado. There are provisions for free and paying patients, and arrangements can be made also for radium treatment in the home.

Public Health Training in Brazil.—Following the report of a special commission sent to Brazil in 1916 to study medical conditions, the Rockefeller Foundation International Health Board entered into an arrangement with the Faculdade de Medicina e Cirurgia at São Paulo for the establishment of a department of hygiene in that institution. The new department—the first of its kind in Brazil—is to be maintained jointly by the medical school and the board for a period of five years, with the understanding that, if at the end of that time it has justified itself, the government will assume its support.

Improved Public Health Service in Brazil.—The agitation for measures to reduce the spread of various diseases throughout Brazil has resulted in the formulation of a set of regulations which are published in the *Brazil-Medico* of April 12. The diseases principally in view are hookworm, malaria and Chagas' disease or Brazilian trypanosomiasis. The service for leprosy is to be separate from the others. The plan outlined is most excellent, but our exchange says it is like a fine body without any head, as the whole functioning of the service is in the hands of the Ministerio da Justicae Negocios Interiores which is already overburdened with its specific duties. The plan provides for cooperation between the national and the state and local service, which share the expense in specified proportions.

Brazilian Neurologists Elect Officers.—At its meeting, March 27, the Brazilian Society of Neurology and Psychiatry elected the following officers: president, Prof. Dr. Juliano Moreira; vice president, Prof. Dr. Aloysio de Castro; general secretary, Dr. Mario Pinheiro; first secretary, Dr. W. de Almeida; second secretaries, Drs. H. Carrilho, Teixeira Mendes, Ant. Costa; treasurer, Dr. U. Vianna; commission on neurology, Profs. Miguel Couto, A. Austregesilo, Oswaldo de Oliveira, Miguel Osorio, Fernandes Figueira and Ernani Lopes; commision on psychiatry, Profs. H. Roxo and Franco da Rocha, and Drs. Rodrigues Caldas, G. Riedel, W. Schiller and P. Pernambuco; commission on legal medicine, Profs. Nascimento Silva, A. Peixoto, Tanner de Abreu, Oscar Freire and Diogenes Sampaio, and Dr. M. Barbosa.

Resignation of Centeno.—Under the heading "Lamentable News," the *Archivos Españoles de Pediatría* publishes a notice that Professor Centeno has resigned the chair of pediatrics at the University of Buenos Aires. The resignation is based on purely personal reasons, it is said. Under another heading it mentions that seven physicians are now competing for the post, including such well known names as Araoz Alfaro, Elizalde, Sixto, Acuña, Navarro and Santas. On account of the retirement of Dr. Centeno from the charge of the children's ward at the Hospital de Clinicas at Buenos Aires, his pupils are planning a testimonial to him to take the form of a handsomely bound collection of the scientific works of all his pupils and collaborators. The collection will form fourteen volumes of 800 pages each, and contain many important works such as Elizalde's monograph on splenomegaly in children; on tumors in the kidneys, by Lugones; on the treatment of gallstone disturbances, by Jorge, Jr.; F. Schweizer's contributions on infant feeding and nutrition, and Navarro's important work on glandular disease in children. The *Semana Médica* comments on this testimonial to Professor Centeno: "'By their fruits ye shall know them.' The gift of this collection will enable Dr. Centeno to realize at a glance the magnitude of his work in the chair of pediatrics. Would that other professors could have as rich a collection of important works to show, and such a pleiad of stars to surround them."

GENERAL

National Board Examination.—The examination held by the National Board of Medical Examiners at Philadelphia, June 2 to 7, had fifty-two candidates, the largest number in the history of that board.

The Campaign Against Tuberculosis.—The U. S. Public Health Service has published a leaflet, one of its "Keep Well Series," entitled "How to Avoid Tuberculosis." It gives the symptoms briefly and simply, and outlines the proper method of living, which, if followed, would not only go far to prevent tuberculosis but many other human ailments.

Antivivisection Legislation Proposed.—Senator Myers of Montana would prohibit experiments on living dogs in a bill just introduced in the Senate. The bill makes it a misdemeanor to experiment or operate in any manner on a dog for any purpose other than to cure or heal it. The law, because of constitutional limitations, would apply only to the District of Columbia, territories and insular possessions. It was referred to the committe of the judiciary.

Bill to Reinstate Officers of Public Health Service.—All physicians who left the Public Health Service to enter the army or navy for the period of the war must be reinstated on application, under the terms of a bill by Senator Jones of Washington. The bill also provides that they be given the same seniority in rank to which they would have been entitled had they not resigned. The bill was referred to the Senate Committee on Public Health and Quarantine of which Senator France of Maryland is chairman.

Amendment to Food and Drug Act Urged.—Congressman Burton L. French of Idaho would amend the pure food and drug act in the misbranding of drugs. He has introduced an amendment to the pure food and drug act providing that every package sent in interstate commerce containing a virulent poison shall be placed in a container bearing the word "poison" printed in red on white, or in white on red, and giving at least one suitable antidote. In the case of liquid poisons, the use of a colored glass roughened bottle is made mandatory.

Legislation Against Venereal Treatment Advertisements.—The transmission through the mails of advertisements relating to the treatment of venereal diseases and sexual disorders is prohibited by a measure introduced by Senator Townsend of Michigan. The publication of all matter relating to sexual cures is made nonmailable matter, except in instances of didactic or scientific treatises which do not call attention to any person from whom treatment or advice may be obtained. The publications of the Public Health Service are also excepted. Violation is to be punished by a fine of $5,000 or five years imprisonment, or both. The bill was referred to the Senate Committee on Postoffices.

Bequests and Donations.—The following bequests and donations have recently been announced:

University of Toronto, Ont., a gift of $25,000 a year for 25 years to provide for a full-time clinician in the department of medicine and a half-time physician in pediatrics by Sir John and Lady Eaton.

Washington University School of Medicine, a donation of $150,000 by the general education board on condition that an equal amount be raised by subscription, this fund to be used for the endowment of a department of pharmacology.

St. Joseph's Hospital, Philadelphia, $1,000 by the will of Marcella Ennis.

Pennsylvania Hospital, Philadelphia, $10,000 by the will of Robert Ralston Stewart.

For a hospital in DeKalb, Ill., $22,000 by the will of Joseph F. Blidden, DeKalb.

Jewish Charities, Chicago, and Michael Reese Hospital each $18,500 by the will of Gustave Freund.

Annual Conference of Health Officers.—The seventeenth annual conference of State and Territorial Health Authorities with the Public Health Service was held at Washington, D. C., June 4 and 5. Surg.-Gen. Rupert Blue presided. The subjects which were taken up at the conference were malaria, child hygiene, problems in interstate health work, control of venereal diseases, public health education, Sanitary Reserve Corps, railroad sanitation, and statistics relating to the 1920 census. Dr. William H. Welch, Baltimore, who represented the Public Health Service at the recent conference of Red Cross societies held at Cannes, France, made a report on the organization of a league of Red Cross societies, for the purpose of promoting public health throughout the world.

One of the most important questions taken up by the conference was that of malaria, most of the discussion dealing with the work accomplished by the Public Health Service, in connection with the sanitation of extracantonment zones.

Asst. Surg.-Gen. Taliaferro Clark, Washington, D. C., discussed the necessity for a nationwide program of child hygiene to be carried on through cooperation between the federal and state governments. Special stress was laid on the importance of having child hygiene work conducted through the present health organizations of the different states.

The Public Health Service made a report of a rapid survey made of federal water supplies in relation to interstate traffic throughout the country in the last few weeks. The Public Health Service also announced a program for assisting state health departments by detailing to each an officer of the service who will assist in epidemiologic and other public health work at the request of the state and health authorities.

In the discussion on public health education, a program was placed before the conference, whereby the Public Health Service will furnish speakers, publications, films and other educational material, provided the states shared in the expenses involved. No final action was taken on the matter, but a committee was appointed to discuss it further, with a similar committee to be appointed by the Conference of the State and Provincial Boards of Health.

The program of cooperation between the Public Health Service and the state health authorities in the control of similar diseases was explained by Assistant Surg.-Gen. Claude C. Pierce. A large number of representatives of the venereal disease control work in the different states were present at the conference, and held a meeting taking up the problems relating to this work . A resolution was adopted by the conference endorsing the bill, known as the rural health act, which would extend the principles of federal aid in rural health work. The text of the resolution follows:

Resolved, That it is the sense of the Conference of the United States Public Health Service with the state and territorial health authorities, meeting in Washington, June 4 and 5, 1919, that on account of the greatly accentuated popular interest in public health work, incident to the examination and findings by Draft Boards, of widespread physical impairment among millions of apparently healthy registrants, and because of the present pronounced restlessness of rural local governments for breaking away from their former attitude of indifference to adequate measures of human conservation and in undertaking with or without the guidance of experienced health agencies, hastily prepared and varied programs of rural health work, that the present moment is of all times the most opportune and crucial for Federal and State Health Authorities to take steps for assisting local rural governments in the development of an economic, efficient and permanent system of rural health work and,

Be it further resolved, That it is the sense of this Conference that the best means for insuring the future of rural health work is the Federal Aid Extension Principle of Government (the wisdom and practicability of which has been demonstrated and established in providing for other rural needs, as in the matter of post roads, vocational education and farm life demonstration work), as represented in H.R.—2845 recently introduced in the present Congress and entitled "The Rural Health Act."

FOREIGN

Landouzy Memorial.—A committee has been formed at Paris to honor the memory of Professor Landouzy by founding at the Faculté de Médecine a museum to be called by his name. A medal is to be struck off to be given to each subscriber. The treasurer of the fund is M. P. Masson, 120 boulevard Saint-Germain, Paris.

Prize Offered by Spanish Gynecologic Association.—The *Archivos Españoles de Pediatria* states that the Sociedad Ginecologico Española has offered a prize of 500 pesos for the best article dealing with endocrinology in relation to infantile pathology, sent in to the secretary before Oct. 31, 1919. Address Mayor 1, Colegio de Médicos, Madrid.

Endowment of Motherhood.—The family endowment committee has laid before the national birth rate commission in London a proposition that the state provide a regular weekly income for families with children under 15 years of age. It is intended that the effect of this endowment will be to induce earlier marriages and will tend to remove the economic restriction of birth rate. The cost to the government will be about $1,200,000,000 a year.

Neutral Doctors Study Nutrition in Germany.—A dispatch from Consul Schmedeman, at Christiania, states that in response to a request received from a number of German and Austrian universities to appoint representatives on a commission of neutral doctors whose task should be to study the present state of nutrition in Germany and Austria, Professor Brandt of the medical faculty has gone to Germany. Sweden, Denmark, Holland, Switzerland and Spain will be represented on the commission. Possibly an American physician will also be asked to join it. The Swedish representatives are Professors Johansson and Gadelius.

Deaths in the Profession Abroad.—Dr. E. A. Tscherning, chief of the surgical department of the Kommunehospital at Copenhagen, one of the founders of the Danish and the *Nordisk Surgical Associations* in which he has served as president, as also in the Copenhagen Medical Society, aged 68.——P. J. Ménard of Paris, one of the younger set of physicians.——Dr. Martin Vallejo Lobón, professor of medical pathology and also of clinical medicine in the Barcelona medical faculty, and author of numerous works on clinical medicine, etc.——Dr. A. Schwob, physician to the French consulate of France at Geneva, Switzerland, for thirty-five years, aged 85.

Royal Army Medical Corps War Memorial.—A memorial is to be erected to the officers and men of all branches of the R. A. M. C. who fell in the war. These number 560 officers and 4,091 men of other ranks. A committee representative of all branches of the corps has been formed. Lieut.-Gen. Sir Alfred Keogh is chairman and Lieut.-Gen. Sir John Goodwin is vice chairman of the committee. The Duke of Connaught is honorary chairman. It is the plan of the committee to erect a permanent memorial or monument in London, with, if possible, replicas in Edinburgh and in Dublin; to create a fund from which grants in aid may be given to the families of members of every rank and branch of the service who have fallen or been disabled in the war or who may be in necessitous circumstances owing to the exigencies of military service; to establish scholarships or memorial prizes for research work. Suscriptions are invited and may be sent to Messrs. Holt and Co., 3 Whitehall Place, London, S. W., and should be described as for "The R. A. M. C. War Memorial Fund."

PARIS LETTER

Paris, *May 29, 1919.*

Tuberculosis a Reportable Disease

The Académie de médecine adopted the following resolution presented by Dr. Vaillard: 1. All cases of open tuberculosis must be reported as soon as the diagnosis is established. 2. The report will be made to an official of the health department, who will be bound to professional secrecy and who will attend to the institution of the necessary prophylactic measures when the attending physician cannot give assurances that these will be carried out. 3. The authorities will provide for needy patients the care necessary to restore them to health and will also give assistance to their families, if required.

The Académie also adopted unanimously the emendations offered by Dr. P. Reynier and by Professor Hayem which comprise the following points: a campaign against alcoholism, including the limitation of the sale of intoxicating drinks; elimination of insanitary homes; better living conditions for the laboring class in the large centers of population; development of the Grancher work; compulsory disinfection of homes, thus giving positive assurance against spread of the disease; establishment of dispensaries, sanatoriums, special hospitals, farm colonies; extension to the other departments of France of the infant welfare work already established in the department of the Seine; introduction of sanitary regulations with reference to abattoirs and stables; the building of good, reasonably priced homes for the working class; prophylactic measures against syphilis.

Inspection of the Surgical Service of the Army

An inspection department of the various surgical services of the army has been created as part of the Service de Santé militaire and will be in charge of an inspector-general. Dr. Sieur, president of the consulting staff of the Service de Santé, has been assigned to this work.

Institute of Child Welfare

The American Red Cross and the Children's Welfare League of the United States have together appropriated 1,500,000 francs for the establishment of an Institute of Child Welfare, on the condition that 1,000,000 francs shall be collected in France for this work. The office of the institute will be located in the buildings of the Paris medical faculty. A committee has been appointed to take charge of the collection of funds in France, and about 500,000 francs has already been subscribed. The secretary of the committee is Dr. B. Weil-Hallé.

Help for Nursing Mothers

The society founded in aid of nursing mothers (Allaitement maternel et des refuges-ouvroirs) recently met in general session under the presidency of Dr. Louis Mourier, under-secretary of state for the Service de Santé militaire, assisted by Mr. P. Strauss, senator from the department of the Seine, and Mr. Mesureur, director of public charities. Dr. Mourier commended highly the coordination of all the various agencies engaged in child welfare. Mr. Abel Combarieu stated that many large problems would soon be attacked for which Baroness Leonino had recently donated a fund of 200,000 francs.

Honors for the Personnel of the American Hospitals

Several officers and nurses of the Field Ambulance at Ferrières-en-Gatinais have received evidences of official recognition at the hands of Dr. Louis Mourier, of the Service de Santé militaire, for services rendered at the front and in the Paris military district, especially during the air raids.

Personal

The council of the Paris medical faculty has appointed Dr. Balthazard professor of legal medicine. Dr. Balthazard is a medicolegal expert and has officiated in a number of sensational cases. Dr. Leon Bernard was appointed professor of hygiene, succeeding the late Professor Chantemesse. Dr. Abadie of Bordeaux was appointed clinical professor of mental diseases, and Dr. Dubreuilh, also of Bordeaux, was made professor of general anatomy and histology in the Bordeaux school. Dr. Spillmann of Nancy was appointed clinical professor of dermatology and syphilis on the Nancy medical faculty.

Dr. Bellencontre has been elected president of the Association générale des médecins de France, succeeding the late Professor Gaucher.

LONDON LETTER

London, May 21, 1919.

An American Hospital for London

The idea of an Anglo-American entente has been taken up not only among the public but in the medical profession with a good deal of enthusiasm. Its latest manifestation is a movement to establish an American hospital in London. The headquarters are to consist of a hospital, a library, lecture theaters, demonstration rooms, reading rooms, and so forth. American physicians will thus possess a rallying point when visiting London. It is understood that Lord Reading has accepted the presidency of the scheme and that Mr. Tait is taking a prominent part in furthering it. It is hoped the new hospital may become a kind of Rockefeller Institute in London.

A Conference of Medical Organizations

The British Medical Association has for some time declined to cooperate with other medical organizations engaged in political work on the ground that its activities cover the whole field and that the objects of the profession are to be achieved by the union of its members in one body, while several bodies mean disunion and weakness. However, the union of the whole profession, at present at any rate, is an impossible ideal. Recently there have been formed several bodies which seem to have come to stay. They profess not to be hostile to the British Medical Association, though their *raison d'être* is that it cannot satisfactorily perform the work which they have undertaken. The British Medical Association has now abandoned the policy of isolation and has consented to confer with other bodies. The approaching formation of a ministry of health has aroused considerable apprehension in the profession, and therefore medicopolitical activity. On the initiative of the Association of Panel Committees, a conference of representatives of the various medical organizations has been held by invitation of the Council of the British Medical Association, to discuss the possibilities of common action, the best means of securing for the Medical Consultative Council of the Ministry of Health the confidence of the great body of the profession, and the best means of securing the support of all medical organizations for the National Insurance Defense Trust. Organizations that were invited to send representatives include the Association of Panel Committees, the Medicopolitical Union, the Medical Parliamentary Committee, the Medical Women's Federation, the National Medical Union and the State Medical Service Association. The nature of these various organizations has been described in previous letters. It will be seen that all phases of medical opinion from the Medicopolitical Union, which is bitterly opposed to state interference in the relations of physicians and patients, to the State Medical Service Association, which is a socialistic body desirous that the practice of medicine should be entirely controlled by the state, were represented. A representative of the Association of Panel Committees (an organization representative of physicians working under the insurance act) stated that the position of his association was that there should be a body directly representative of panel committees and looking specially after their interests. His association had used influence to modify the composition of the Insurance Acts Committee in that direction. It desired to bring about unity in the profession and thought the time had come when the British Medical Association should foster a federation of all medical associations. A representative of the Medicopolitical Union agreed that there was danger in the competition now going on between various medical organizations, and also in the existence of rival deputations on the same subject. His union did not desire to injure the British Medical Association or to rival it. He submitted, as a basis of an understanding, that: (*a*) There should be recognition of the trade union as a possible valuable adjunct in medical organization; (*b*) the Medicopolitical Union should be frankly recognized as the official body representing those members of the profession who wished to belong to a medical trade union; (*c*) the British Medical Association should recognize the Medicopolitical Union as the agent for the profession in collective bargaining in the final resort—that is, if ordinary means of persuasion had failed, and there was any question of refusing to accept or renew contracts or anything which might be construed as being in "restraint of trade," the matter should be dealt with by the Medicopolitical Union (it may be explained that anything done "in restraint of trade" is illegal except in the case of a trade union; (*d*) further conferences should be held to define limitations of work and prevent overlapping, and (*e*) there should be mutual agreement in important matters before any action is taken by way of joint deputations. A committee was appointed to consider the best ways of promoting common action.

The Dogs' Protection Bill

Strong opposition to the dogs' protection bill (The Journal, May 3, 1919, pp. 1311, 1313) is being organized in the profession. A deputation of fellows of the Royal Society of Medicine has lodged a protest with the government. Sir George Makins, president of the Royal College of Surgeons, referred to a resolution of the council of the college condemning the bill, and said that during the years in which he had been practicing there had been a very general change in the trend of thought with regard to surgical science; practice was being founded less and less on any form of empiricism, and more on rational data which in large part had been forthcoming as a result of experiments on animals. There were very strong reasons why the dog should be used. In the first place, there was an ample supply of dogs. A large number of dogs were now being destroyed in order to get them out of the way in a manner no more humane than that of the laboratory. The dog was suitable with regard to its size and the character of its tissues. Experiments did not entail suffering. They had to be performed with a particular technic, and if wounds were permitted to become infected the experiment was spoiled; in the absence of infection, the wounds were not painful. Vascular surgery was founded entirely on experiments on dogs. The technic of such an experiment as transfusion of blood had been perfected as a result of experiments on dogs. Experiments on dogs had furnished the knowledge that in place of destroying or obliterating an artery when wounded it was possible to repair it. They had shown also that an organ might be removed from an animal and an organ from another animal put in its place. All these were things from which it was possible to predict future fruit. It seemed extraordinary that at a time when the whole nation had suddenly awakened to the fact that success in war or in industry was bound up with experimental research, a few persons who were unable to appreciate the importance of experiments on vital processes should be so far successful in their attempts to hinder the advance of science in matters of life and death to the human race. He regarded the dog as doubly protected, for, in the first place, operations had to be performed in the most careful manner or they were useless, and, in the second place, any abuses were already prevented by legislation. He did not find fault with the restrictions already imposed.

Sir William Osler said that this bill was a test case—not for the dog, or for the medical profession, but for the intelligence of the House of Commons. If there was one thing more certain than another in the history of the science of medicine, it was that experiment had brought it to its present position, and if the experimental work which had been done from Harvey onward were examined, it would be found that four fifths of it had been done on the dog. When a student in Berlin in 1873, he saw in a small laboratory a most interesting series of fundamental experiments on the localization of brain function. These experiments were made on dogs; it was not until later that monkeys were procured and worked on by Horsley and others. In 1889, he saw in America a man who had had for five or six years recurring convulsions of a very serious character, and as a result of that early work on the dog, King removed a tumor from that man's brain, and the man lived for thirty years. There were now hundreds of persons alive and well and comfortable from whom brain tumors and spinal cord tumors had been satisfactorily removed simply because of early canine experiment. No young surgeon could grow to his full measure unless he was an experimental surgeon and in his own career had opportunities for doing experimental work.

Sir Hamar Greenwood, parliamentary secretary to the Home Office, said in reply that the government was opposed to the bill and would do its best to prevent the coming into force of a measure for stopping research. He had put down an amendment to the bill which provided that when an applicant wished to experiment on a dog he must state that the object would be frustrated unless a dog was used and that no other animal was available for the purpose. This would put dogs in the same position as horses now occupied under the law. Sir William Osler said he would prefer a straight negative: the amendment would impose an additional and unnecessary restriction. Sir Hamar Greenwood said that the amendment was made for further supervision rather than restriction, and Sir Watson Cheyne said that as a matter of policy it would be well to accept the amendment.

MEXICO LETTER

City of Mexico, *June 2, 1919.*

A New Sanitary Code

The Departamento de Salubridad Pública has drawn up a new Codigo Sanitario which is to be submitted to the Chamber of Deputies for consideration and adoption, as it is believed that the regulations now in vogue are inadequate as they have not been revised to keep pace with progress. Among the innovations proposed in the new Code is the prohibition of the practice of medicine to foreigners unless they can prove that they have taken the respective medical course in a medical college in good standing. At the same time, the regulations provide that the practice of medicine is to be permitted to persons without a degree on condition that they announce on their placards that they are "médicos prácticos." The regular physicians with a degree must publicly announce their educational credentials specifying the university or other institution where they obtained their diplomas. It is considered probable that in view of the urgent character of other matters before the legislature, such as legislation on labor and on affairs connected with the oil industry, which the chamber of deputies now has under consideration, that the executive authority will be authorized to issue officially the new Code.

Smallpox

The state of Guerrero, on the Pacific Coast, is now taking its turn in the contingent which we habitually pay to variola. According to dispatches from there a large number of persons have been attacked and the mortality is causing alarm as fully 20 per cent. of the victims die.

University Interchanges

The Universidad Nacional here has received through diplomatic channels an appeal from two members of the teaching force of the University of Colombia—I do not know of what faculty—who are desirous to come to Mexico for teaching purposes and with the aim to draw closer together the intellectual and friendly relations between the two countries.

The rector of the University of Morelia has asked the University of Mexico to bear in mind the students of the former university in case it is decided to send a party of students from Mexico to complete their studies in some institution of the same kind in the United States, a subject which has been much talked of lately.

Personal

Dr. Jesús Diaz de León, professor at the Escuela de Altos Estudios here, and at one time its director, has recently died at an advanced age. He was distinguished as a linguist, held the chairs of Hebrew, Greek and Latin, and wrote a work on "Greek Roots in the Spanish Language," and a translation from the original Hebrew of the "Song of Songs." He belonged to various scientific societies at home and abroad.

Dr. José León Martínez, professor of clinical medicine in the Faculty here and in the Escuela Medico-Militar, has been elected to membership in the Academia de Medicina. The paper he read on that occasion was on the symptomatology of influenza.

RIO DE JANEIRO LETTER

Rio de Janeiro, May 5, 1919.

Rural Sanitation

The government has promulgated a law, organizing rural sanitation in the outskirts of Rio de Janeiro and the states of Brazil, the principal aim of which is to combat hookworm disease and malaria. All expenses are borne by the federal government for Rio and the territory of Acre, situated in the extreme north of the republic.

In accordance with the constitution, public health service within state limits is under the direction of the state government. When under the direction of the federal authorities, half of the expenses are paid by the latter; but if directed by the state, the Union will enter only with one third. In case a state government paying half of the expenses, signs a contract with the Rockefeller Foundation to combat at least two endemic infectious diseases, the Union will pay one quarter.

The president of the republic (Relfim Moreira) praised highly the excellent work done by the Rockefeller Foundation in the states of Rio, Minas and São Paulo.

The director of public health exercises no jurisdiction over the rural sanitation service; that is, under the direction of the secretary of the interior. This is a great mistake, as has been pointed out to the government by various medical associations.

Protection of Railway Employees Against Infectious Diseases

The secretary of public works has initiated a service, obliging all federal, state and private railway companies, throughout the country, to protect their employees against infectious diseases, especially hookworm and malaria.

Eradication of Leprosy

The chief of the Rockefeller Foundation, in agreement with the secretary of the interior, who is responsible for the public health service, will send one of his assistants to travel through the country investigating leprosy and to see what means can be taken to eradicate this hideous disease.

In the last days of April, the foundation stone was laid for a leprosarium, which is being built in Mogy das Cruzes, by the government of São Paulo, in the state of the same name. It will contain all modern improvements, including a theater, cinema, library, playgrounds, etc. Its cost is estimated at about $1,200,000.

Commission to Draw Up Sanitary Code

The government has appointed five prominent physicians and a leading consulting lawyer to draw up a sanitary code, although according to the point of view of the secretary of the interior, this code can be enforced constitutionally only in the limits of the capital and the territory of Acre.

Reorganization of Oswaldo Cruz Institute

The Oswaldo Cruz Institute has been reorganized. Seven new assistants and six subassistants have been appointed.

Marriages

Francis Patrick Machler, Capt., M. C., U. S. Army, Chicago, on duty at Embarkation Hospital, Camp No. 2, Newport News, Va., to Miss Ruth A. Steele of Rogers Park, Chicago, at Richmond, Va., May 29.

George Braunlich, Lieut., M. C., U. S. Army, Davenport, Iowa, on duty at the Department Hospital, Manila, P. I., to Miss Karen Beck, San Francisco, at Manila, April 30.

Winfred Overholser, Lieut., M. C., U. S. Army, Westboro, Mass., to Miss Dorothy Stebbins of Worcester, Mass., June 4.

Frank Thomas Fort, Louisville, Ky., to Miss Elizabeth A. Brown of Baltimore, June 4.

Leon Unger, Chicago, to Miss Nina Kleinman of New York City, June 1.

Deaths

James Ewing Mears, Philadelphia; Jefferson Medical College, 1865; aged 80; a fellow of the American Surgical Society; honorary president of the Philadelphia Academy of Surgery; lecturer on practical surgery and clinical gynecology in his alma mater; professor of anatomy and surgery in the Pennsylvania College of Dental Surgery; acting executive officer of military hospitals during the Civil War; once captain in the quartermaster's corps of the Indiana Volunteers, and surgeon in chief of the Pennsylvania National Guard; author of a textbook on "Practical Surgery"; died at his home, May 28.

Frederick Porteous Henry ⊕ Philadelphia; College of Physicians and Surgeons in the City of New York; 1868; aged 74; one of the original one hundred members of the Association of American Physicians; professor of principles and practice of medicine in the Woman's Medical College of Pennsylvania, Philadelphia, since 1891; a fellow, once president and honorary librarian of the College of Physicians of Philadelphia; author and editor of several works on practice of medicine and history; died at his home, May 24.

James Mason Barstow, Council Bluffs, Iowa; College of Physicians and Surgeons, Keokuk, Iowa, 1880; Bellevue Hospital Medical College, 1884; aged 64; professor of applied therapeutics in the John A. Creighton Medical College, Omaha; president of the staff of St. Bernard's Hospital, Council Bluffs; once president of the Missouri Medical Society; chief of the board of insanity commissioners, Council Bluffs for more than twenty years; died at his home, May 19, from heart disease.

William Gilson Farlow, Cambridge, Mass.; Harvard University, 1870; aged 74; professor of cryptogamic botany in Harvard University since 1879; a fellow of the American Association for the Advancement of Science, vice president in 1887 and 1898, and president in 1905; honorary L.L.D., Harvard, 1896; University of Glasgow, 1901, and University of Wisconsin, 1904; Ph. D., University of Upsala, Sweden, in 1907; a botanist of international reputation; died at his home, June 3.

John Augustus Donovan ⊕ Lewiston, Me.; New York University, New York City, 1866; aged 77; once president of the Maine Medical Association, and Androscoggin County Medical Society; surgeon in chief of the Central Maine General Hospital, Lewiston, from 1891 to 1906, and thereafter surgeon emeritus of the institution; a member of the state legislature in 1913 and 1914; died suddenly while in church, May 24.

Julius Martin McLeod, Lincoln, Neb.; Ensworth Medical College, St. Joseph, Mo., 1890; Lincoln (Neb.) Medical College, 1895; aged 53; professor of surgery in his alma mater; professor of principles and practice of surgery and clinical surgery and president of the corporation of the Nebraska College of Medicine, Lincoln; a member of the surgical staff of the New Lutheran and St. Elizabeth hospitals, Lincoln; died at his home, May 18, from pneumonia.

John Frederick Barnett, West Haven, Conn.; Yale University, New Haven, 1869; aged 72; a member of the Connecticut State Medical Society; for many years treasurer of the borough of West Haven; for nearly a quarter of a century health officer (coroner) of the town of Orange; died in the New Haven Hospital, June 4, from cerebral hemorrhage.

George Wieseckel, Brooklyn; New York University, New York City, 1884; aged 56; dispensary physician to St. Catherine's Hospital, Brooklyn, from 1885 to 1889, and vaccinator and physician on the summer corps of the Brooklyn Health Department from 1888 to 1892; died in St. Catherine's Hospital, May 29, after an operation for appendicitis.

Sarah C. Jackson, Greensburg, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1891; Southwestern Homeopathic Medical College, Louisville, Ky., 1894; aged 77; an inmate of the Indiana Odd Fellows' Home at Greensburg for two years; died in that institution, May 11, from asthma.

Watson Meredith Gentry, Franklin, Tenn.; New York University, New York City, 1855; aged 88; for four years a surgeon in the Confederate service during the Civil War; surgeon in chief of hospitals at Montgomery, Ala., in 1864 and 1865; died at his home, May 18.

Oliver Grimshaw, Swedesboro, N. J.; Hahnemann Medical College, Philadelphia, 1890; aged 58; who had been under

---

⊕ Indicates "Fellow" of the American Medical Association.

treatment in a sanatorium for nervous disease; died at his home, May 27, from the effects of poison, self-administered, it is believed, with suicidal intent.

George Sloan, North Yakima, Wash.; Bellevue Hospital Medical College, 1878; aged 62; a member of the Washington State Medical Association; surgeon of the Northern Pacific Coal Company from 1888 to 1899; died at his home, May 23, from heart disease.

Charles H. Wells ⊕ Shelton, Wash.; Michigan College of Medicine and Surgery, Detroit, 1893; aged 58; who was injured in an elevator accident in San Francisco, April 16; died from his injuries in the Central Emergency Hospital, San Francisco, April 17.

Charles Henry Brockett, New Haven, Conn.; Yale University, New Haven, 1886; aged 56; for many years town physician, and in charge of the medical department at Springside Home; died at the New Haven Hospital, May 16, from cerebral hemorrhage.

Adolph Gustav Sund ⊕ **Asst. Surg., Lieut. (j. g.), U. S. Navy;** University of Minnesota, Minneapolis, 1917; aged 26; on duty at the U. S. Naval Hospital, Fort Lyon, Colo.; died at Cragmore Sanatorium, Colorado Springs, Colo., May 8, from tuberculosis.

Philip Joseph Catoggio, New York City; Eclectic Medical College of the City of New York, 1910; aged 34; a member of the Medical Society of the State of New York; visiting physician to the Italian Hospital; died at his home, May 29.

Ernest Heber Deaton, Hot Springs, S. D.; Ohio Medical University, Columbus, 1896; aged 43; a veteran of the war with Spain; assistant superintendent of a sanatorium at Black Hills; was found dead in bed at Johnstown, Pa., May 19.

Lester M. Drake, St. Joseph, Mo.; Eclectic Medical University, Kansas City, Mo., 1904; aged 40; was run over by a train at New Hampton, Mo., May 23, and died the same day from his injuries at Ensworth Hospital, St. Joseph.

Ashton Morrell Baldwin ⊕ **Lieut., M. C., U. S. Army,** Marion, Ind.; University of Louisville, Ky., 1917; aged 28; who had been on duty at Base Hospital No. 21, Denver; died at Aurora, Colo., April 16, from tuberculosis.

Arthur Duncan Sinclair, Toronto, Ont.; University of Minnesota, College of Homeopathic Medicine and Surgery, Minneapolis, 1908; Syracuse (N. Y.) University, 1918; aged 36; died at his home, May 25, from pneumonia.

Cassius M. Porter, Hillsville, Pa.; Philadelphia University of Medicine and Surgery, Philadelphia, 1871; aged 72; for several years a member of the board of education; died at his home, May 20, from cerebral hemorrhage.

Floyd Burke Riley ⊕ Monrovia, Calif.; Rush Medical College, 1908; aged 35; formerly of Chicago; instructor in surgery in his alma mater; died in Monrovia, May 16, from tuberculosis of the larynx.

Jedidiah Howe Adams, Paoli, Pa.; University of Pennsylvania, Philadelphia, 1889; aged 53; from 1889 to 1892; editor of the *University Medical Magazine;* died suddenly at his home, in Paoli, May 26.

Bruno John Ferdinand Getzlaff ⊕ Sutton, Neb., formerly of St. Joseph, Mich.; Medical College of Ohio, Cincinnati, 1892; aged 51; died at his home, May 22, from chronic nephritis.

Somerset R. Waters, Watersville, Md.; University of Maryland, Baltimore, 1858; aged 89; a member of the Medical and Chirurgical Faculty of Maryland; died at his home, May 30.

John Dubois Dolan, New York City; Medical College of the State of South Carolina, Charleston, 1900; medical superintendent of the Reception Hospital; died at his home, May 28.

Ralph Maclay Lashell, Media, Pa.; Jefferson Medical College, 1888; aged 76; for fifty-two years a practitioner of medicine; a veteran of the Civil War; died at his home, May 20.

John Alphonsus Lanigan, Niagara Falls, N. Y.; New York University, 1877; aged 64; at one time a member of the Provincial Medical Board of Nova Scotia; died at his home, May 21.

Nicholas Walter Pendergast, Syracuse, N. Y.; University of Syracuse, N. Y., 1901; aged 40; medical inspector in the public schools from 1907 to 1915; died at his home, May 26.

David Theodore Martin ⊕ Pomeroy, Iowa; Rush Medical College, 1882; aged 64; local surgeon of the Illinois Central Railroad; died at his home, May 22, from nephritis.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

PULVOIDS CALCYLATES COMPOUND

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report, not so much because the preparation with which it deals is of any great importance, but as a protest against the large number of similar irrational complex mixtures which are still offered to physicians.

W. A. Puckner, Secretary.

Pulvoids Calcylates Compound (The Drug Products Co., Inc.) are tablets each of which is claimed to contain:

> "Calcium and Strontium Disalicylate, 5 grs.; Resin Guaiac, ½ gr.; Digitalis, ¼ gr.; Cochium [colchicum?] Seed, ¼ gr.; Squill, ¼ gr.; Cascarin, 1/10 gr. with aromatics."

"Pulvoids Calcylates Compound (Sugar coated orange color)" is advertised (*Medical Times,* January, 1919) as being "Analgesic-Antipyretic and Diuretic," and is included in the preparations designated by the advertiser as "Approved Remedies for LaGrippe and 'Flu.'" The claim that "Their tolerance is remarkable" refers not to the physicians who tolerate such products, but to the alleged fact that Pulvoids Calcylates are tolerated remarkably well. The advertisement continues:

> "May be given persistently and continuously without gastric disturbances."
>
> "They are uniformly efficient. More certain in effect than the ordinary Salicylates."

It would be difficult to find an advertisement of equal length containing a greater number of misleading or directly false statements than are found in this one. The Journal (April 22, 1916, p. 1307) has called attention to the lack of justification for this absurd mixture of drugs and has discussed the preparation with especial reference to its use in acute rheumatism, in which the salicylates occupy a special field. The advertisement just quoted mentions La Grippe and "Flu" (or Influenza) as special fields of usefulness for this preparation. This, apparently, is merely an attempt to spread the sail for any breeze. Salicylates have a field of usefulness in influenza in that they often afford relief from pain. There is no reason to suppose that a mixture containing calcium and strontium salicylates—the "Calcium and Strontium Disalicylate" of Pulvoids Calcylates is probably a mixture of calcium and strontium salicylate[1]—has any greater salicylic effect than an equal amount of sodium salicylate. On the other hand, it is worse than useless to give colchicum, squill and digitalis for the relief of such pains.

Should cardiac dilatation develop, and digitalis medication be required it would be impossible to adjust the dose of such a mixture with special reference to the digitalis action, which alone would be indicated for that condition. No educated physician at present would think of giving resin of guaiac merely because his patient required digitalis, nor would he administer "cascarin," whatever that may be, in fixed doses, every time he gave a dose of a salicylate.

It is impossible to recognize the several effects induced by this therapeutic omneity, and the medical profession should consider it an insult to be offered mixtures such as Pulvoids Calcylates Compound.

Pulvoids Calcylates Compound is, per se, of no great importance; it is one of a type. It has been selected as one of the utterly irrational and therefore potentially dangerous mixtures, that may be found by the score or the hundred in the catalogues of practically every pharmaceutical manufacturing firm in the United States.

Correspondence

MENINGOCOCCUS INFECTION

To the Editor:—The very unusual opportunity afforded Major Herrick to study an epidemic of meningitis in which the septicemic type predominated (THE JOURNAL, Jan. 26, 1918, p. 227; *Arch. Int. Med.* **23**:409 [April] 1919) has given rise to a great deal of much needed discussion of the subject of meningitis. Of course, it has long been generally believed that the meningococcus gains access to the meninges by way of the blood stream. In most cases, however, this invasion of the blood stream seems to be of the nature of a bacteremia rather than a septicemia, since blood cultures are so often negative; since the number of organisms, when present, is usually so small; and since their presence is so brief, as shown by the failure in most instances to obtain a second positive blood culture.

Moreover, it has also been recognized for a long time that there is a septicemic type of meningitis, usually rare, in which the invasion of the meninges may be late, or even may not occur. In the last instance, of course, the term "meningitis" is a misnomer. It is obvious that cases of this kind are more likely to have the extrameningeal infection which Major Herrick has encountered in the epidemic at Camp Jackson.

It is probable that this type of case occurred at Camp Jackson in greater numbers and was more thoroughly studied than it has ever been before. Nevertheless, this must not make us lose sight of the fact that this type of case is unusual in civilian practice, at any rate. Indeed, it did not predominate in all of the epidemics at the army camps, notably at Fort Riley, where a hemorrhagic eruption was present in only 6 per cent. of the cases followed by recovery and in 14 per cent. of the fatal cases. At Camp Beauregard, on the other hand, the rash was a more prominent feature, being present in about 80 per cent. of cases. Stone and Truitt report from Fort Riley that "positive blood cultures were obtained in a larger percentage of cases with petechiae, while negative blood cultures were as a rule obtained in those patients not manifesting petechiae." It should be further noted that while Herrick at Camp Jackson and Landry and Hamley at Camp Beauregard obtained a much lower mortality by combining the intravenous and the intraspinal use of serum, Stone and Truitt had about the same result by the two methods: 28.1 per cent. for thirty-two patients treated by the combined method, and 28.8 per cent. for the total 191 cases. Of course, in considering the lower mortality obtained by the combined method by Herrick and by Landry and Hamley, one must remember that this was employed during the latter part of the course of the epidemic, when the mortality is practically always declining; also that experience in treating meningitis is a factor that always influences the mortality.

While it is quite definitely proved that the intravenous administration of serum is of value in cases of the septicemic type, it by no means follows that it is of value in the more common type with a sudden onset without a rash or with a few petechiae that last only a day or two and with signs of a meningitis, not a septicemia. Indeed, the results at Fort Riley seem to prove that it is not of value in these cases.

I confess that I am somewhat afraid of the reactions following intravenous injections, as they are at times much more severe than those following intrathecal injections. I have in mind one patient that died immediately after an intravenous injection of the serum, though he had been improving under the intraspinal treatment, and necropsy showed that his meningitis had practically cleared up. An overenthusiastic attending physician, however, wishing to leave nothing undone, insisted on an intravenous injection. Perhaps if adequate precautions had been taken, the unfortunate accident might have been avoided; but I think the doctor who gave this treatment was probably quite as competent and careful as the average physician will be. Another patient developed signs of cerebral hemorrhage while serum was being given intravenously, and died about eight hours later without recovering consciousness. Of course, this may not have been the result of the intravenous injection.

Several other severe but not fatal reactions have come under my observation or to my knowledge. If I err in wishing to avoid intravenous injections unless they are definitely indicated, I am in excellent company, for Netter says, writing even of meningococcal septicemia: "It is, therefore, more advantageous to substitute intrathecal injection, which is less dangerous than the intravenous one, which is apparently the most logical method." This is particularly interesting because Netter had earlier advised the intravenous treatment. Of course it must be kept in mind that serum injected intraspinally passes from the subarachnoid space into the veins, while the reverse action does not take place.

But the most important reason for carefully defining the use and the limitation of the intravenous injection is the fact that in some instances that have come to my attention, physicians have received the impression from the emphasis laid on the value of intravenous injections that they may be as good as, if not better than, intraspinal injections; in fact, that they may even replace the latter. For some reason, physicians generally seem to regard the technic of intravenous injection as easier than intraspinal, and would, if it were a question of choice, adopt the former. A study of Major Herrick's contribution leaves no doubt that he did not intend to give this impression. But he has, I think, failed to emphasize sufficiently the fact that the type of case at Camp Jackson is a heretofore unusual one.

In regard to the question of terminology, the use of "cerebrospinal" certainly seems superfluous, as all kinds of meningitis usually affect the meninges of both brain and cord. It has seemed to me that the term "epidemic meningitis" is simple and clear since the meningococcus is the only organism that causes epidemics of meningitis, and also it ought to be easy to adopt since physicians are accustomed to speak of "epidemic cerebrospinal meningitis." The term "meningococcus meningitis" is perhaps preferable, since it exactly defines the etiology; but it might not be so easily adopted, as physicians are not so used to it.

JOSEPHINE B. NEAL, M.D., New York.

PHENOL WITH HYDROGEN PEROXID FOR LOCAL APPLICATIONS

To the Editor:—Referring to Dr. Soresi's article (THE JOURNAL, May 3, 1919, p. 1288), I should like to call attention to the procedure employed by me for more than eight years.

If one applies liquid crystallizable phenol (full strength) with a brush or a swab to the surface of the skin or of a mucous membrane, a whitish spot results, followed shortly by local anesthesia. This method can be used, as suggested by Dr. Soresi, for many operations; it will cure light infections, as from ingrowing toe nails, furuncles, acne, ulcerations, or infection of the hysterovaginal folds. I have suggested crystallizable phenol, since that liquefied by the addition of alcohol or glycerin does not produce such an intense blanching and is less efficient.

Now comes my accidental discovery. If after the white spot appears we touch it with undiluted hydrogen peroxid, it will not disappear if the tissues are normal; if the submucous or subepidermic tissues have suffered alterations, the white spot will darken until it becomes black, and the nearer to the surface the affected tissues lie the darker it will become. This black spot is in reality a scar which can be opened slowly, since it is anesthesized, and the incision will surely open a way for the pus, débris, etc. It is a splendid method of diagnosis, prognosis and treatment.

Let us suppose that we have to deal with a Velpeau's syphilitic chancre healed in the "shirt button" way; the hardness remains and there is no suppuration. This chancre is not really healed, but just covered by the membrane or skin which protects it. It is touched with liquid phenol and forms a whitish spot. It is washed with a swab soaked in peroxid to make the spot disappear, and the white stain becomes gray, and in some places there are some darker or black spots indicating the presence of some abnormal tissues.

were licensed by virtue of a commission in the Medical Corps. The following colleges were represented:

Connecticut March Examination

Dr. Charles A. Tuttle, secretary of the Connecticut Medical Examining Board, reports the written and practical examination held at New Haven, March 11-12, 1919. The examination covered 7 subjects and included 70 questions. An average of 75 per cent. was required to pass. Of the 28 candidates examined, 18 passed and 10 failed. The following colleges were represented:

College PASSED	Year Grad.	Per Cent.
Yale University	(1913)	84.2
Georgetown University	(1918)	79.1

Book Notices

The Blind, Their Condition and the Work Being Done for Them in the United States. By Harry Best, Ph.D. Cloth. Price, $4. Pp. 763. New York: The Macmillan Company, 1919.

The author, whose previous compilation entitled "The Deaf" is well known, has now prepared this work of reference on conditions of the blind in the United States. The first part is general, giving statistics, compilations of judicial decisions and statements regarding the economic condition of the blind, and the cost of this deformity to the state. The second part deals with the prophylaxis of blindness and quotes freely from well-recognized statistics as to various causes. It takes up the general subject of heredity in its relation to loss of sight, follows with a discussion of trachoma, ophthalmia neonatorum and other diseases, and then considers blindness, accidents and methods of prevention. In one chapter of this part of the book the author demonstrates that blindness has, within a measurable time, shown on the whole a decrease, although not a material one, and that the chances are that the decline will continue. The final chapter of this part discusses organized movements for the prevention of blindness. The third part is concerned with the education of blind children. It is largely historical, discussing developments in various states, and giving special attention to the facilities available both from the standpoint of financial provisions and as concerns the qualification of various schools. The fourth part, "Intellectual Provision for the Adult Blind," traces the development of the Braille system, analyzing the literature at present available for the blind and enumerating the libraries that have been established. This section also includes a discussion of homes for blind adults and blind children, and industrial establishments providing these unfortunates with a means of economic independence. Several chapters are devoted to indemnities for loss of sight and to pension systems for the blind. Part six is devoted to the organizations interested in the care of the sightless.

The author has rendered a great service in compiling under one cover the extensive amount of valuable data that are available in this book. It is almost encyclopedic in character, and no one who is at all interested in the care of the blind, from any point of view, should fail to avail himself of this most useful work.

Sane Sex Life and Sane Sex Living. By H. W. Long, M.D., M. R. C. Cloth. Price, $5. Pp. 157. Boston: Richard G. Badger, 1919.

This book, we are told, was prepared especially to fill a long-felt want, that is, to supply a book which physicians may recommend to patients who require information on sex matters and sex living. Unfortunately, the book advances views and opinions that would not be endorsed by physiologists, much less by social workers. The author seems to believe that it is necessary to stimulate the sex interest and the sex function, and lays particular stress on methods for this purpose. We cannot commend the book as a safe one for the purpose for which its author states it was written.

Psychotherapeutics. By Frederick H. Gerrish, James J. Putnam, E. W. Taylor, Boris Sidis, George A. Waterman, John E. Donley, Ernest Jones, Tom A. Williams and Morton Prince. Cloth. Price, $1 net. Pp. 186. Boston: Richard G. Badger.

This book, of which the first edition appeared in 1909, consists of a series of papers on psychotherapeutics by various authors. These essays were originally published in the *Journal of Abnormal Psychology* and then gathered in book form. For the purpose of the present edition some revisions have been made, bringing the book up to date. For those wishing a beginning knowledge of psychotherapy, the book will be found suggestive.

A Manual of Gynecology. By John Cooke Hirst, M.D., Associate in Obstetrics, University of Pennsylvania. Cloth. Price, $2.50. Pp. 466, with 175 illustrations. Philadelphia: W. B. Saunders Company, 1918.

This summary of Dr. Hirst's lectures is a most practical work. The chapters on the breast, the rectum and diseases of the urinary tract are especially good. The subject of gynecology is briefly and systematically covered. As a concise discussion of the subject, this book is excellent.

The Diagnostics and Treatment of Tropical Diseases. By E. R. Stitt, A.B., Ph.G., M.D., LL.D., Rear Admiral, Medical Corps, U. S. Navy. Third edition. Cloth. Price, $2 net. Pp. 534, with 119 illustrations. Philadelphia: P. Blakiston's Son & Co., 1919.

This book by Admiral Stitt is well known as a practical guide to its subject. In the third edition only minor changes have been made, with the exception of the section on trench fever, which has been extensively rewritten, these changes of course being required by the newer war medicine researches.

Disease and the Odor Humanus.—The emanations from the skin vary with every passing phase of health, and in pronounced disease the altered smell may be easily noticeable. Inasmuch as all constitutional diseases are mirrored in the blood, and inasmuch as the cutaneous and respiratory emanations tend to alter with every alteration of the blood, it is probably no exaggeration to say that an all-wise physician with a sufficiently delicate sense of smell, could diagnose most (constitutional) diseases by the mere smell of his patient. But we have not arrived at that stage yet.—*Medical Press.*

Duty of Employer Employing Physician for Employees

(Woody v. Carolina Spruce Co. (N. C.), 97 S. E. R. 610)

The Supreme Court of North Carolina says that the plaintiff and the defendant had entered into an agreement whereby the plaintiff was to pay out of his wages one dollar a month to the defendant, and, in consideration of this, the defendant agreed to furnish a competent physician to treat the plaintiff in case of sickness or injury. This regulation of the defendant applied to all its employees. The plaintiff averred that a Dr. Smith, the physician employed by the defendant, was unskilful and incompetent, and that when the plaintiff broke his right arm it was set by Dr. Smith and the president of the defendant, who was reported to have practiced medicine at one time, and that the operation was performed with such gross unskilfulness that the plaintiff was seriously and permanently injured. The defendant contended that the nonsuit granted should be sustained on two grounds: First, that there was not sufficient evidence to go to the jury that the doctor was an unskilled and incompetent surgeon, or, if he was, that the defendant knew of it or might reasonably have known of it; and, second, that if the doctor were unskilled, the plaintiff knew of that fact and, notwithstanding his full knowledge, as shown by his cross-examination, accepted his service, and was not permitted to complain of the defendant. But the evidence of two physicians tended to prove that the operation was very unskilfully performed and that the plaintiff suffered injury thereby. This of itself tended to prove incompetence on the part of those who performed the operation. There was also evidence that the defendant had knowledge, or facts sufficient to put it on inquiry, of Dr. Smith's incompetence and that, notwithstanding it, continued him in its service. Besides, there was evidence that the plaintiff, some time before he was injured, complained to the president of the company of Dr. Smith's incompetence, and when he was injured the president assured him that he and Dr. Smith were fully competent to perform the operation and that the plaintiff in submitting to the operation relied on such assurance, as he had a right to do. Viewing the evidence in this most favorable light for the plaintiff, as the court must do in cases of nonsuit, the court is of the opinion that the trial judge erred in granting a nonsuit; but should have submitted issues to the jury with appropriate instructions. The defendant was under no legal obligation to employ a physician to treat its employees; but, when it assumed to do so and to deduct a monthly sum from their wages for medical attention, it was under obligation to exercise due care in selecting the physician and in continuing him in its service.

Physicians Not Liable for False Imprisonment

(Springer v. Steiner et al. (Ore.), 178 Pac. R. 592)

The Supreme Court of Oregon reverses the judgment and dismisses the cause, in this action wherein the plaintiff obtained a judgment for $2,500 damages against two physicians, a Dr. Howard and a Dr. Holcomb, for alleged false imprisonment arising out of the plaintiff's having been confined in the county jail and then committed to the state insane asylum. The court says that, as to Dr. Howard, the evidence went only to the extent of showing that he believed the plaintiff insane, and tried to induce her to leave her association with a man who claimed to be a "New Thought Healer," whatever that may be, and whom Dr. Howard evidently considered a fraud and quack, and go to their home with Dr. Howard and his wife, who was the plaintiff's sister. He did not deny that he thought the plaintiff insane, but denied that he ever suggested she be sent to the asylum. He was not present, or in the city, when the proceedings were had in reference to her sanity, and there was absolutely no evidence that he even suggested or in any way participated in the proceedings. His motion for a directed verdict in his favor should have been allowed.

Nor was it claimed that Dr. Holcomb was the cause of the confinement of the plaintiff in the county jail, or of any treatment she received there. His connection began lawfully in obedience to a requirement of the county judge to examine the plaintiff as to her mental condition. There was no evidence as to what took place at the examination; but it appeared, independent of the certificate of the physician and the record made by the court, that there was an examination made, which the plaintiff was pleased to call a "farce," and there was the record made by the county court, which recited every jurisdictional fact concerning the examination. The objection was urged against this record that no warrant of arrest was issued by the court to bring the plaintiff before it for examination as to her sanity; and it was true that there was no record of the issuance of such a warrant, but it was also true that there was no provision of law requiring a warrant for that purpose. She was before the judge, and Dr. Holcomb and another physician were appointed to examine her as to her sanity, and on such examination she was duly adjudged insane.

The burden of proof was on the plaintiff to show, either that the physicians made no examination as to her condition, or that the certificate was maliciously false. Her opinion that it was a "farce" stated no probative fact. Her statement that no question was asked her in a 15-minute examination, which she admitted was made, which "tended to an examination of her mental condition," was another conclusion stating no fact on which a verdict could be founded. She testified that after her release from the asylum she had a conversation with Dr. Holcomb, in which he impliedly admitted that his certificate was based on information derived from the relatives. If such was the fact the jury would have a right to consider it in determining whether the certificate was negligently given, but not that it was given maliciously or in bad faith.

It must be remembered that this was not an action against Dr. Holcomb for malpractice in not using reasonable skill and diligence in examining into and diagnosing the plaintiff's condition. It was an action for negligently causing the plaintiff to be falsely arrested and imprisoned in the asylum. Whatever may have been the character of the examination (and the record made the county judge, who had general supervision over it, say it was "careful"), the defendant Holcomb did not and could not arrest or cause the plaintiff to be confined in the asylum. His examination and certificate would be utterly worthless in themselves to cause the confinement of the plaintiff. They were merely evidence (of a high order it was true) which the county judge might accept or reject. The court should have directed a verdict as to the defendant Holcomb.

Standardization of Wassermann Reaction.—Comparative studies of various methods for the collection and washing of blood and in the preparation of erythrocyte suspensions for this test were made by Kolmer and Brown. With the fresh blood of persons, sheep and oxen, the method of collection by defibrination or in an anticoagulating fluid, had no apparent influence on the red blood corpuscles so far as their suitability for hemolytic antigen in the Wassermann reaction is concerned. Human blood cells secured by breaking up coagulums in saline solution were slightly less resistant to serum hemolysis. The authors found that small amounts of blood are best collected in an anticoagulating fluid. They advise that fresh blood cells should be used. Ordinary physiologic saline solution proved as suitable for washing cells as Locke's, Ringer's and Locke-gelatin solutions. The numerical concentration of a corpuscle suspension varied according to the duration and speed of centrifugalization in the last washing and according to method of measuring the corpuscle mass; best results were secured by measuring the corpuscles in an accurately graduated centrifuge tube after the final washing. It was noted that variation in the numerical concentration of corpuscle suspensions may influence the results of serum hemolysis; for this reason the same hemolytic antigen must be used in the preliminary complement and hemolysin titrations as in the Wassermann tests, unless the suspensions are prepared with uniform accuracy. The fresh erythrocytes of different healthy persons and sheep were found quite constant in their resistance to serum hemolysis. The use of suspensions of corpuscles from different persons and sheep does not constitute a source of error in the Wassermann test if technical conditions are correct. Preserved blood may be used in the preparation of hemolytic antigen for the Wassermann test and for the immunization of rabbits, but fresh blood is always preferable. Preservation with liquor formaldehydi and saccharose solutions was found practicable for periods of two to four weeks; the liquor formaldehydi method is quite simple and to be preferred. Methods for preserving blood and a method for preparing the red corpuscle suspension for a standardized test are described.

Syphilis in Senility.—Since 1915 Wile has had four cases of syphilis in senility under observation and treatment. The ages of the patients were 60, 62, 64 and 79, respectively. Of these, all were genital infections, following coitus. Two were serious as evidenced by iritis in one, iridocyclitis, glaucoma and early central nervous involvement in the other. Three of the four persons, including the one aged 79, were sexually potent. The fourth acquired his infection during attempted intercourse, although he was impotent and had no libido. The oldest person, aged 79, was exposed in June, 1918. In October, a painless lesion appeared on the penis. Early in January a generalized eruption appeared on the body. The patient had no headaches and except for a glaucoma he felt perfectly well. The blood Wassermann reaction was four plus positive. Notwithstanding the negative clinical findings the spinal fluid showed 132 cells, marked increase in albumin and globulin and a four plus Wassermann reaction. The patient remained under observation about six weeks, during which time he received five injections of neo-arsphenamin, varying from 0.2 to 0.4 gram, and one injection of arsphenamin, 0.1 gram. He suffered no reactions and the local lesions disappeared entirely. After the first injection the iridocyclitis and glaucoma rapidly disappeared, and up to the time of his discharge no further eye symptom had manifested itself.

Alcoholic Argyll Robertson Pupils.—Menninger reports a case of the Argyll Robertson pupil and other reflex changes commonly associated with neurosyphilis in a patient not suffering from neurosyphilis, or from influenza, or from dementia praecox. The only demonstrated etiology was acute alcoholism. With the fixed pupils there was a speech defect, a paretic facial expression, tremulous tongue and hands, unequal knee and ankle jerks, and a rather defective memory. Altogether this made a fairly typical picture of "alcoholic pseudoparesis."

Antigen in Complement Fixation Test.—Roderick claims that cholesterinized alcohol human heart extract is probably the most sensitive antigen used in the complement fixation test for syphilis. In a small number of tests, its use results in a slight degree (10 per cent. or less) of inhibition, in cases not syphilitic. This antihemolytic tendency can be overcome by proper titration of complement. Roderick advises that cholesterinized human heart antigen should never be used alone, but controlled by an antigen less sensitive. It is especially valuable in the control of treatment, remaining positive for a considerable length of time after all other antigens are negative.

"Provocative" Wassermann Test.—In a series of about 150 cases of treated syphilis of all kinds, Pollitzer and Spiegel did not find a single clear case of a provoked reaction; while the assumption of a cure in all these cases was obviously untenable. In a series of cases temporarily negative, selected as probably not cured, the "provocative" test failed to indicate the presence of syphilis though the subsequent course of the cases proved that the syphilis was not cured. Therefore, Pollitzer and Spiegel regard the "provocative" arsphenamin injection as a useless and often misleading procedure.

Colloidal Gold Reaction.—Methods for making colloidal gold and directions for doing the test are given by Weston. The characteristics of a good gold solution are stated and the nature of the substance causing the reaction is discussed.

Treatment of Syphilis in Tuberculous Patients.—Elliott presents the data in ten cases treated with arsphenamin. His observations lead him to conclude that mercury should be used with great care in tuberculous patients, that the deleterious effect is not immediate, but appears several months after the institution of administration of the drug. Therefore, arsphenamin seems to be the drug of choice in such cases, but should be given in small doses and at long intervals, inasmuch as the ordinary dosage accentuates active foci and is prone to cause a flare up in latent lesions.

Blood Sugar in Nephritis.—The average digestion blood sugar level in 113 normal individuals examined by Williams and Humphreys was 0.107 per cent., the values ranging from 0.07 to 0.14 per cent. The range of the blood sugar level in a series of sixty cases of miscellaneous diseases, chiefly gastro-intestinal disorders and pernicious anemia, excluding diabetes, nephritis and infections, was from 0.07 to 0.16 per cent., with an average of 0.115 per cent. In a series of nine cases of carcinoma there was a moderate elevation of blood sugar, 0.12 to 0.16 per cent. In a series of twenty-two miscellaneous infections, chiefly influenza, pneumonia, and streptococcus, the range was from 0.07 to 0.15 per cent., with an average of 0.11 per cent. In the early stages of nephritis, when the general metabolism of the body is but little disturbed, blood sugars, as a rule, are normal. In the last stages of nephritis, when the patient is in uremia, the blood sugar will be found very high, often equaling the severe stages of diabetes. Other important metabolic constituents of the blood will be found correspondingly increased, presenting a picture of complete metabolic failure. A third group of cardiovascular cases, characterized by high blood pressure and little or no evidence of renal disturbance, usually exhibits blood sugar levels slightly higher than normal. In severe cases of nephritis, patients may excrete small quantities of sugar in the urine, frequently giving rise to the misapprehension that true diabetes exists. In such cases the blood sugar level is inappreciably influenzed by carbohydrate restriction, and these patients should not be subjected to the discomfort of a rigorous diabetic diet Failure in nitrogen metabolism precedes, often by months, the rise in blood sugar, so that the latter has a rather serious prognostic omen.

Blood Sugar in Diabetes.—The blood sugar levels in 127 cases of diabetes were studied by Williams and Humphreys, fifty-six males and seventy-one females, making in all 1,106 blood sugar determinations. In their study of the renal threshold for sugar in diabetes, they found no constant blood sugar level for the appearance of urinary sugar. There is no striking relation between the height of the renal threshold and the duration of the diabetes. It would appear, however, from the analysis of sixty-five cases that the threshold tends to rise with the the increasing duration of the disease. Younger diabetics as a rule have low or normal thresholds. The threshold rises with advancing years. When the diabetes is mild or quiescent, the point at which the kidneys eliminate sugar is stationary; but when the disease becomes progressive, the threshold tends to rise. Before death the blood sugar renal threshold may reach great heights with little or no sugar appearing in the urine. A rising renal threshold for sugar in the face of careful dietary treatment is a serious prognostic sign. A high renal threshold for sugar in mild diabetes under proper dietary regulations usually indicates some complication, such as arterial hypertension. A high renal threshold for sugar may mean a physiologic expedient to conserve food material. The authors believe that persistent high blood sugar levels promote exhaustion and rapid decline of function, and the high threshold is merely a safety measure. In severe diabetes, where extremely low diets are necessary to maintain life, the high threshold is essential to take care of the seriously impaired carbohydrate metabolism. In the treatment of diabetes it is desirable to main the blood sugar level as nearly normal as possible, even though severe restrictions in diet may be necessary for this purpose, notwithstanding the fact that the high threshold will permit of a much more liberal diet without the appearance of sugar in the urine. The authors believe that diabetes should be controlled on the basis of the blood sugar level rather than by urine tests. A persistent low blood sugar level may be regarded as an extremely favorable sign. A persistent high blood sugar level, in spite of undernutrition, usually points to an unfavorable outcome. In their experience, cases which hitherto had been intractable and had shown progressixe loss of food tolerance, when the blood sugar level was disregarded, have been greatly benefited and their tolerance increased by regulating the food intake so as to insure, when possible, a normal blood sugar level. While they regard 0.15 per cent. as the maximum normal digestion blood sugar level, they believe patients are safer when this level is not higher than 0.13 per cent.

Glucose Tolerance in Diabetes.—Williams and Humphreys endorse the glucose tolerance and utilization test proposed by Hamman and Hirschman and as later modified by Janney as a means of differentiating those metabolic disorders in which traces of reducing substance are excreted in the urine from renal diabetes and mild diabetes mellitus. As a means of measuring the degree of disturbance in carbohydrate metabolism in hyperthyroidism and other endocrinal disorders, they have found it to be much superior to tests depending solely on the determination of urine sugar. Renal diabetes is a definite physiologic disturbance, easily distinguishable by this procedure from true diabetes. The sugar tolerance and utilization test is particularly useful in differentiating those cases of very mild diabetes in which there are exhibited no clinical symptoms of the disorder. The various degrees of failure of carbohydrate metabolism in the more evident cases of diabetes are most strikingly shown by this method.

Epidemic of Influenza at Camp Merritt.—Of 4,979 cases of influenza treated at the Camp Merritt Base Hospital, 1,015 patients, or 20.4 per cent., developed bronchopneumonia, and of these latter, 31 per cent. died—a mortality for all the admissions of 6.3 per cent. The average time of onset of bronchopneumonia was 4.03 days in a series of 726 recovered cases, and 5.7 days in a series of forty-seven fatal cases. The temperature, pulse and respiration curves differed in the fatal and recovery patients. The fatal cases had a short course; in a series of thirty-nine such cases the duration of the pulmonary involvement averaged only 4.7 days. The temperature curve seldom assumed the sustained plateau so common in lobar pneumococcus pneumonia, but was rather of an irregular, remittent type, ranging from 99 to 105 or even to 107 F. Of greater value than either the temperature or the pulse was the respiratory rate, which was always raised. A climb in the rate, sometimes precipitous, usually more gradual, presaged death. The systolic blood pressure was normal in the acute stage of the disease, the diastolic was at times often as low as 55. In the cases of primary influenzal bronchopneumonia the average leukocyte count was low (5,000 to 15,000 cells per c. mm.). The presence of the hemolytic streptococcus tended to increase this average count but slightly, although the individual counts varied from 5,000 to 30,000 or even higher. Several cases were observed with counts below 2,000 cells, all of which were fatal. In a small series of these bronchopneumonia cases the coagulation time of the blood was determined and found normal. The urine showed, as a rule, a trace of albumin with granular and hyaline casts. Treatment was purely symptomatic, although stress was laid on keeping the intake of total fluids as great as possible. Digitalis, camphor and occasionally strychnin were used in an attempt to control the rising pulse rate; they seemed at times to be effective. When the patient was unable for any reason to take fluids well and became "dried up," with dry tongue and skin, tap water was given by rectum, and in a few cases salt solution (always made up with freshly distilled water) was injected intravenously in daily doses of 500 c.c. each. The results from the use of vaccines were unsatisfactory. Rackemann and Brock are of the opinion that all fatal cases develop "bronchopneumonia" before death, and that this "bronchopneumonia" is but a later manifestation of pure influenza, because: first, the lung signs develop in many cases during the primary influenza; second, the pathologic picture of the lungs in influenzal bronchopneumonia is distinctly characteristic, being quite unlike the picture seen in other forms of pneumonia.

Leukocytes in Irritable Heart Cases.—A slight leukocytosis was found by Gay in the unclassified group of patients with "irritable heart." The figures correspond to those found in patients with organic heart disease. There is a relative lymphocytosis, the limits being between 15 and 51 per cent. An eosinophilia is likewise present. A marked leukocytosis occurs in both patients and controls after the injection of epinephrin. This increase is much greater in the patients with positive reaction than in the controls, who did not respond to the drug. The morphologic studies of the blood in cases of "irritable heart" showed nothing of significance that might assist in the diagnosis.

Effect of Fasting and Various Diets on Liver Injury.—When chloroform anesthesia is indicated, Davis and Whipple advise giving liberal amounts carbohydrates and milk for at least two days preceding the anesthesia. They emphasize strongly that it is dangerous to give chloroform to man or animal whenever a fasting period has preceded the administration of the anesthetic.

*Cerebellar Gait. I. L. Myers, Chicago.—p. 14.

Cerebellar Gait.—Graphic records of the cerebellar gait made by Meyers seem to indicate that there is no asthenia (Luciani) in the muscles affected by the cerebellar lesion nor is there any arrhythmia in the sense that Luciani employed that term. There is no difference from the normal in the force with which the flexed and advancing limb returns to the vertical on the ground so that the height of the line is the same in the affected as in the normal limb. The primary essential effect of the cerebellar lesion is the change in the rhythm of the affected limb with relation to the corresponding limb on the normal side, the change exhibiting itself in the hyperactivity of the extensors so that the former limb extends and initiates the step too early as compared with the same action of the latter limb.

Blood Urea Nitrogen in Catatonia. W. C. Rappleye, Foxboro, Mass.—p. 130.

Lesion in Putamen.—Newmark cites the case of a man, aged 65 years, who after having experienced a transient disturbance of articulation some time before, suffered a slight impairment in the use of the left extremities, which appeared to him as a numbness or awkwardness in the action of the left hand and a loss of facility in moving the left foot toes, and was associated with a slight tremor of the left hand on voluntary movement and of the lid when he shut the left eye. In the remaining two and a half years of the patient's life no further progress in the affection of the extremities was observed, but about one year and a half before his death paralysis of the bladder and weakness of the anal sphincter supervened. There was no Babinski sign or involvement of the pyramidal tracts, and all the tendon reflexes were normal, but the record contains no mention of the abdominal or cremaster reflexes. Subsequently lymphatic leukemia was noted, and of this disease the patient died. At the necropsy a lesion was found in the putamen resembling in many particulars what Wilson described as progressive lenticular degeneration.

War Traumas of Spinal Cords.—Grimberg contends that an injury to the spinal cord alone does not exist; that the trauma must be conceived as a root and cord trauma. War traumas of the spinal cord are nearly always associated with edema or hemorrhages which may clear up in the course of the disease and change the entire clinical picture.

*Influence of Alcoholism in Production of Hallucinations in General Paralysis of Insane. S. L. Immermann, Philadelphia.—p. 289.

Second Attack of Poliomyelitis After Fifteen Years' Interval.—The patient in this case was a girl, aged 18 years. When 3 years of age she had an attack of acute anterior poliomyelitis with febrile state, paralysis of both upper extremities and transient weakness of both lower extremities. Several months after this attack almost complete recovery of the left upper extremity had taken place and on the right side there was a partial return of function with, however, a well marked residual paralysis of the deltoid, forearm supinators and all the intrinsic muscles of the hand. At the age of 18, the patient complained of general malaise, weakness, especially of the lower extremities and inability to stand or walk. The onset ten days previously was rather insidious with general malaise and pain in the lumbar region and lower extremities which came on following gymnastic exercises. Associated with this was a mild febrile syndrome and a catarrhal rhinopharyngitis which continued for four or five days. On the eighth day after the onset she rather suddenly lost power in the lower extremities so that she could neither walk nor stand. Paralysis of the left lower extremity was complete; of the right only partial. The clinical course was comparatively uneventful. There was no fever after the third day. When the patient left the hospital four weeks after admission the function of the involved muscles was but slightly improved. Six months later there was definite improvement, perhaps 15 or 20 per cent.; the lost function of the lower extremities was regained.

Alcoholism and Hallucinations of Insane.—In a study made by Immermann of seventy-three paretics, the patients fell into several clinical groups which tended to remain fairly distinct. Hallucinations were found to occur in certain of these groups and tended to remain confined to those groups. Excessive alcoholism occurred in only some of the hallucinatory groups, and was at most an indirect factor in the production of hallucinations. Some paretics showed a conspicuous absence of hallucinations; certain manic types showed hallucinations and a high incidence of excess of alcohol use, abnormal make-up and absence of knee jerks, but other hallucinatory patients did not show this combination.

Two Cases of Arteriovenous Aneurysm of Popliteal Vessels.—Both of Pybus' patients were shot through the calf, the bullet making a clean entry and exit. In both cases the popliteal artery and vein were damaged, leading to an arteriovenous aneurysm. Swelling and pulsation of the calf were present in each. Exploration revealed damage to both main vessels of such a character that repair was impossible, and in such a position that simultaneous ligature of the popliteal, anterior, and posterior tibial arteries and their corresponding veins was necessary to control bleeding. In both cases recovery ensued without any loss of vitality of the distant portions of the limb and with full functional use.

*Results of Vaccine Treatment in Filarial Lymphangitis in British Guiana. F. G. Rose.—p. 81.
*Epithelial Xerosis of Conjunctiva in Natives of the Sudan. R. G. Archibald.—p. 81.
Trichophyton Currii. A. J. Chalmers and A. Marshall.—p. 83.

Vaccine Treatment of Filarial Lymphangitis.—Having demonstrated a streptococcus in cases of lymphadenitis and lymphangitis, Rose has been experimenting with a vaccine prepared from streptococci isolated from these conditions, and he now reports on the progress which has been made with this method of treatment. After extended trial he has arrived at the conclusion that the most effective method of giving inoculations was in a series of three, the first inoculation consisting of 100 million dead cocci and the next two of 200 million, an interval of two weeks separating the inoculations. The reactions following the inoculations are almost invariably mild, and the doses may be doubled in longstanding cases. With this vaccine, Rose has inoculated sixty persons more than six months back, nineteen of these cases being of fairly long standing—that is to say, all longer than one year, and some two or three years or more since the first attack, the rest being recent cases. Of these nineteen patients, nine patients have had no recurrences since inoculation, while the others have had attacks varying in frequency and intensity; but most are positive that the attacks have grown milder in character. Of the forty-one recent cases, thirty patients were inoculated a year ago or earlier, and none has had a single attack since. Of the other eleven, three cannot be traced; two remained free for over a year, while the remaining six were done six months ago, and have had no recurrence yet.

Epithelial Xerosis of Conjunctiva.—In three cases of epithelial xerosis of the conjunctiva observed by Archibald, diphtheroid bacilli allied to the *B. xerosis* group were present in the xerotic areas. Experimental inoculation with material obtained from one of the cases produced xerosis of the conjunctiva in a rabbit.

Missiles as Emboli.—Sutton cites cases which prove conclusively that missiles occasionally become dangerous emboli. A soldier died after being wounded in several places, including the arm, chest and knee. There was a hole in the right side of his chest, in the right leaf of the diaphragm, and in the inferior vena cava 2.5 cm. below the place where the hepatic vein joins the caval vein. A flat piece of shrapnel, 2 cm. square and 12 mm. thick, lay in the right ventricle of the heart. There was no wound of the heart. The piece

Milian reports a case in which the symptoms of a fulminating lethargic encephalitis developed as the young woman was convalescing from influenza.

Acromegaly and Diabetes.—Labbé's patient, a miner of 48, has hypertrophy of the pituitary, also acromegaly, while at the same time he presents symptoms of diabetes, but there is no wasting away and pituitary treatment displayed no action on the polyuria. The glycosuria, however, was remarkably influenced by pituitary treatment, plus reduction of intake of carbohydrates, the sugar in the urine dropping from 129 gm. to zero in four months. The case seems to confirm the assumption that not the pituitary itself, but irritation of some center in the base of the brain is responsible for the diabetes and the polyuria.

Diabetes with Insufficiency of the Pancreas.—Faroy relates that the pancreas digestion had been interrupted in a man of 58 to a degree suggesting cancer of the pancreas or ampulla of Vater, but the absence of jaundice and of pain during the two years excluded malignant disease. Continuous thirst, insatiable appetite, polyuria and 140 gm. of sugar in the twenty-four hours had preceded the digestive disturbance. Under a course of pulverized pancreas treatment the digestion and stools returned to clinically normal, but the diabetes was not modified by it in the least. Thus, the external secretion of the pancreas was favorably modified or supplemented, while the internal secretion was not influenced.

Anomalous Spinal Fluids.—Lochelongue discusses the paradoxical findings in some among 250 specimens of cerebrospinal fluid examined. Abnormally small amounts of ash, as also lymphocytosis, are encountered in bacterial meningitis with a subacute course. A small amount of ash with a clinical picture suggesting acute disease is evidence of an acute infection superposed on a slow meningeal infection or an exacerbation of some previously latent infection. One case confirms the opinion that, even with pronounced polynucleosis, a high sugar content excludes bacterial meningitis unless, on account of diabetes or traumatism, the sugar content previously had been extraordinarily high. He also emphasizes the possible differential importance of his constant finding of an abnormally high sugar content at the time of an epileptic seizure. In one case of poliomyelitis in a young man, he found 0.45 gm. albumin; 1.20 gm. sugar, and 0.52 gm. urea in the spinal fluid.

Appendicitis as Complication of Movable Kidney.—Rolando objects to the statement that appendicitis is a frequent accompaniment of movable kidney. In his own experience with twenty-five cases of right nephropexy for movable kidney he found signs of appendicitis only in three cases. In the single case of unmistakable acute appendicitis, the kidney disturbances were of many years' standing, while the appendicitis had only developed recently.

Enrichment of Tubercle Bacilli in Urine.—Vivier comments on the rapidity, simplicity and reliability of the Ellermann-Erlandsen method for enrichment of the tubercle bacilli in the urine by centrifuging for twenty minutes, diluting in 5 or 6 c.c. of a 1 per four hundred solution of sodium carbonate, and incubating for twenty-four hours at 37 C. After this they centrifuge anew for twenty minutes, decant and dilute the sediment in 5 or 6 c.c. of a 1 per four hundred solution of sodium hydroxid. Then heat in the water bath to boiling for five minutes, and centrifuge anew. The staining can be done by the Spengler technic. All the cellular and bacterial débris except the tubercle bacilli are destroyed by these measures and the diagnosis can be made at once without waiting for inoculation of animals.

Plastic Induration of the Corpora Cavernosa.—Corbineau has compiled 188 cases from the literature and reports a case personally observed in which one or more small lumps, like cherry stones, developed in the corpora cavernosa. He tabulates the details of the entire 189 cases with four pages of bibliography; the description of the first case dates from 1743. Medical treatment rarely gives results, and then only incomplete. Surgical removal of the lumps may be called for if they cause appreciable disturbance, but it is useless to attempt it until the induration has reached its complete development. Radium treatment has never been applied in any case to date, to his knowledge.

Removal of Incarcerating Metal Ring.—Fonseca gives an illustration of forceps with a circular saw in one blade. It can be run by a thumbscrew. The other blade is narrow and flat, and is slipped inside the incarcerating ring, where it serves as a bed for the saw as it cuts through the ring.

Preferable Means for First Immobilization of Fractures. J.-P. Lamare.—p. 767.
Tardy Tetanus after Amputation. J. Perret and M. Bernheim.—p. 785.

Indications for Secondary Suture.—Piollet and his coworkers reiterate that even secondary suture after a war wound without fracture gives much better functional results than when the wound is allowed to heal spontaneously, and should be applied to all clinically sterile wounds even if bacteriologic examination is impracticable. The coexistence of the streptococcus and the staphylococcus gives the least favorable conditions for the success of the suture, but one alone does not always prevent healing by primary intention.

Chemical Index of Fitness of Wound for Suture.—Mestrezat asserts that it is possible from the chemical findings in the secretions of the wound to estimate with some degree of accuracy the organic defense that is being offered to infection. The serous fluid that had soaked into the dressings was systematically examined in some cases and the content in chlorids, albumin, and the proteolytic capacity, etc., were recorded over long periods and compared with the state of the healing process. The test found most instructive was what he calls the formaldehyd index or suture coefficient. It indicates practically the putrescibility of the secretions of the wound, that is, the percentage of the proteolytic nitrogen (ammonia, amino acids) found in the 100 c.c. of water in which the used dressings have been soaking for half an hour. He calls it the *azote de protéolyse titrable au formol* test, and describes the simple technic. His tabulations of the findings in large numbers of cases show the rise and fall of the index parallel to the clinical conditions in the wound. The ease and rapidity with which this simple and inexpensive test can be applied justify its use on a large scale as an instructive guide, other things being equal.

Primary Suture with Infected Wounds.—The results of primary or delayed primary suture of clinically infected wounds were surpassingly good in the 395 cases reviewed, even although sometimes the wound had to be opened and excision done during the secondary period.

Primary Suture in Stages.—Leriche reports most excellent results in extremely extensive war wounds sutured in three stages, the deeper layers first, then the middle layer and finally the skin, allowing an interval of two days between each. He declares that the results are as perfect as with primary suture, while it permits suturing many wounds which otherwise would forbid suturing.

Torsion of Spleen.—Petridis gives colored plates of the spleen removed from a young man which showed the effects of torsion and of a cancerous growth on the upper pole. The downward displacement of the spleen had brought the lower margin below the pubis. In a second case the spleen had sagged into the right iliac fossa and adhesions connected it with the appendix. This patient was a woman of 32, and the spleen was twisted twice on its axis, and had dragged down the end of the pancreas. Both patients recovered after splenectomy.

Paris Médical

April 19, 1919, **9**, No. 16

*Rachitis. M. Vargas (Barcelona).—p. 309.
*Typhus. G. Heuyer.—p. 318.

Rachitis.—Vargas reiterates that rachitis is a national problem in nearly every country. It is a world scourge, preventing the normal development of the young, leaving them damaged not only in their bones, but also in their mental and moral faculties. He expatiates on the prodromic symptoms which, when heeded, permit the removal of the causes. This prodromic stage includes the period from the first signs that the child is not thriving normally to the manifest deformity in the skeleton, evident in the skull during the first six months of life and in the fifth and sixth ribs in infants from 6 to 20 months old. The child whimpers when it is moved, the scalp sweats freely, the head is swung from side to side as soon as it touches the pillow and digestion is imperfect. A waxy pallor is one of the earliest symptoms, and the hemoglobin percentage is low. The very first sign of rachitis is a special constipation. The feces are hard; the rectum is unable to expel the lump and it sticks in the anus until aided by mechanical means. There may be fissure of the anus and prolapse of the rectum. Other signs of rachitis soon follow. The constipation may alternate with diarrhea, but in both types of stools the content in calcium salts is above normal. The eruption of the teeth and walking are retarded, proportional to the age at which the rachitis develops.

In the second stage the disease, which commenced with the blood, attacks the blood-producing organs, the bone marrow in particular. The resulting abnormal conditions in the marrow and cartilage make their effects felt in the development of the bone. But other organs are affected likewise, the nervous system, the muscles, skin and mucous membranes, as Vargas describes in detail, defining rachitis as a "toxic, infantile dystrophy characterized by hemolysis, irritability of the blood-producing system and by osteism." The tendency in time is to a spontaneous recovery, but the damage from it can only be warded off by removing the cause. For this he gives calomel in case the stomach is out of order, restricting the diet to milk alone, and aiding digestion with hydrochloric acid and pepsin. When the condition has improved under this and the digestion permits, he gives one or two drops of 10 per cent. phosphorized oil. Cleanliness, out of door air, possibly the seashore, complete the cure. He has never witnessed any benefit from epinephrin, bone marrow or thymus extract.

Typhus.—Heuyer enumerates the various differential signs in typhus, calling attention in particular to the rigidity of the rectus muscles in the portion reaching from the ribs to the umbilicus, and also to the pain on pressure of the external margin of the rectus muscles at a point where the muscle is crossed by a line passing from the umbilicus to the anterior angle of the tenth rib. On the right, this angle of the tenth rib corresponds to Flemming's point for bladder disease. The painful point in typhus thus cannot be confused with Flemming's point above or McBurney's point below. Pressure on this point causes the patient to grimace, and there is also a vasomotor reflex in the face, which grows red and sweats when the two points above and near the umbilicus are pressed. The cerebrospinal fluid also shows characteristic changes, leukocytosis, high pressure and high albumin content. The polynuclears predominate during the acute phase, and then the reaction is a lymphocytosis. Lumbar puncture usually relieves the headache and tranquilizes the patient.

Presse Médicale, Paris

April 28, 1919, **27**, No. 24

*Spinal General Anesthesia. V. Riche.—p. 225.
*Traumatisms of the Wrist. H. Colleu.—p. 226.

Spinal Anesthesia.—Riche says that he has applied general rachianesthesia *par la voie lombaire* in 60 cases out of a thousand in which he has used ordinary spinal anesthesia. The latter permits all operations under the diaphragm, but with a modified Jonnesco and Le Filliatre technic he performed operations on the neck, chest and arms. In 3 of the cases there was a tendency to partial narcosis, but most of the time the patients were able to converse with the nurse in charge. In 30 per cent. of the cases there was transient retching from twenty to thirty minutes after the injection. With his modified technic, the dose of procain (novocaine) was 1 cg. per 5 kg. of the body weight. The puncture is made in the first or second lumbar interspace, the patient lying on his side, withdrawing 10 or 15 c.c. of the spinal fluid. Then the anesthetic in an 8 per cent. solution is very slowly injected. He never uses epinephrin with it, but in the course of the injection he draws some of the spinal fluid up into the syringe several times to mix it well with the anesthetic. He declares that this technic can compete on an equal footing with general anesthesia and blocking the trunk nerve, but local anesthesia is preferable to all other technics when conditions permit it.

Traumatisms of the Wrist.—Colleu gives an illustrated description of the types of traumatism most often encountered, and expatiates on the frequent misinterpretation of the findings. This is due to lack of thorough clinical examination before applying radioscopy. The findings with the latter may otherwise prove misleading. The principal injuries encountered are fracture of the radius or of the scaphoid bone, partial rupture or tearing loose of some of the ligaments of the carpus, with or without dislocation of the bones of the carpus.

Reconstruction of Fractured Bone.—Aimes discusses the drawbacks of different methods of osteosynthesis, and describes with illustrations a technic which he regards as superior to others. A light, narrow metal bar pierced with a strip of holes is laid along the bone, and over this are placed a row of narrow elastic clips, shaped like a capital C, with a small peg in the center which fits into one of the perforations in the bar. Each end of the clip is bent in and pointed to make a small claw which holds firm to the bone. Even in a case of submalleolar fracture the clips held the bones in perfect position for repair.

Mechanical Orthopedics.—Scherb discusses the drawbacks and limitations of present methods of mechanical training of impaired function, and enumerates a number of principles which have hitherto been neglected in this work. He is the director of a national institution for training crippled children, and his experience has enabled him to devise means to combat each special form of motor disturbance and to persisted unmodified in all but one case. In two of the other cases, the retina in the other eye became detached at the fourth or sixth month of a later pregnancy. But artificial delivery at once in both cases was followed by the restoration to place of the retina, with recovery of reading vision. All these cases seem to teach that the longer the interval between the detachment of the retina and the delivery, the smaller the chance of restoration of the retina to place. Consequently it is extremely important to interrupt the pregnancy at once.

Fracture of the Long Bones.—Haugseth analyzes the present findings in 145 cases of fractures of the legs treated at the Rikshospital between 1907 and 1917, mostly industrial accidents.

Juvenile Deforming Arthritis.—In Nicolaysen's case the lad of 17 had been operated on a year before for arthritis deformans and subluxation of the femur head. The limping had been much improved by the intervention, and there was no further pain. After sudden death ascribed to the status lymphaticus and hypertrophied heart, the hip joint showed changes which rendered it probable that typical Calvé-Perthes' disease had preceded the juvenile deforming arthritis. The Calvé-Perthes' disease had induced a certain deformity in the joint, the head was egg-shaped, the neck short and broad, and this had modified static conditions in the joint and brought on the arthritis as the bone became fully ossified at puberty.

Retention of Urea with Kidney Disease.—Scheel reviews 25 cases of acute hemorrhagic or chronic nephritis, terminating in recovery or material improvement. There was retention of urea in both blood and spinal fluid, but it was never over 1.94 per thousand, and it displayed a downward tendency. In another group of 19 cases the urea content was over 2 per thousand, and the cases all terminated unfavorably in a few months or weeks. With over 4 per thousand, death is imminent within a few days. At the same time, low urea content is not inevitably a sign of good prognosis, as even with normal content, uremia may develop within a few months, with content up to 1 per thousand, within a few weeks. The highest retention was with chronic glomerular nephritis and true contracted kidney. The retention of urea is independent of the tendency to dropsy. There is usually a high blood pressure with retention of urea, but they are independent of each other and either may occur alone. Headache, anorexia and vomiting in the course of the chronic nephritis should attract attention, but they are less reliable as elements for the prognosis than the objective retention of urea.

His experience suggests further that eclampsia with and without uremia may be two separate entities. Bruun of Stockholm recently called attention to the difference between the residual nitrogen in the spinal fluid and in the blood in these two groups. The difference may amount to 16 mg. per 100 c.c. blood serum, in the normal, but the difference is greater with nephritis, from 17.5 to 32.2. In 6 patients with true uremia and convulsions, the difference ranged from 43 to 114. In 5 of Scheel's cases the retention of over 2 per thousand urea was the result of some mechanical obstacle, congenital valve formation in the ureter, cancer of the prostate, urethral stenosis or other cause. The practical importance of this group lies mainly in the imperative necessity for reducing the intake of nitrogen in the diet, especially as a preliminary to an operation on the prostate. The amount of urea retained on a nitrogen-poor diet and on a milk diet should be studied for purposes of comparison. Scheel found in a series of cases that the nitrogen retention became much less on changing from a milk diet to an albumin-poor diet, the figure dropping from 90 to 26 mg.; from 141 to 32, etc., per 100 c.c. blood serum. The urea content of the blood serum, occasionally determined, is a guide for regulation of the diet, showing when it is necessary to restrict the intake of nitrogen. Over long periods it is impossible to get along with less than 50 to 60 gm. albumin per day, but for a short time much less than this will suffice.

Addison's Disease.—Motzfeldt declares that bronzing is by no means an indispensable element in the picture of Addison's disease. He describes the case of a woman of 43 who had had spondylitis twenty years before and had been treated at various times for pains in the abdomen. Gastric ulcer and stenosis in the bowel had been suspected, and she had lost much in weight. Suddenly she developed headache, vomiting and diarrhea with extreme asthenia and weakness. Slight bronzing of the back of the hands was noticed; the pulse was fast and small, often scarcely perceptible. The temperature was subfebrile and the tolerance for sugar, unusually low. Epinephrin by the mouth produced no effect, but after subcutaneous injection there was pronounced transient improvement. She died within two months, and both suprarenals were found almost entirely destroyed by tuberculous processes. He compares this case with those on record and reviews the literature. In treatment it might be better to use an extract of the suprarenal cortex intsead of epinephrin, as a deficiency of epinephrin does not seem to be the cause of the low pressure. Our positive knowledge of Addison's disease is still meager, especially its pathogenesis. Experiments on animals have only added to the confusion, as the blood pressure does not drop for days after removal of the suprarenals. When the pressure does drop, it cannot be modified even by continuous intravenous infusion of epinephrin.

*Operations on the Chest for Pulmonary Tuberculosis. C. Saugman.—p. 585.

Thoracoplastic Operations for Pulmonary Tuberculosis.—Saugman reviews the experiences in this line at the Vejlefjord Sanatorium, a total of twenty-six operations in the last two or three years. The indications for the operation were about the same as for artificial pneumothorax; in fact, this had been attempted in every case beforehand. Local anesthesia is very important, and it is astonishing to witness the patient's indifference to the extensive operation. One patient began to converse on some trivial subject in the midst of the operation. Large amounts of the anesthetic are required to block the nerves, and one girl of 18, in good condition, died soon after the operation. It had been hastened on account of her collapse, so that the resection of five ribs and the suturing took only fourteen minutes; 190 c.c. of a 0.5 solution of procain (novocain) had been used in this case, after a preliminary injection of 0.015 morphin an hour before the operation. She had also been given a little sedative the evening before. Necropsy failed to explain the cause of death. In another case, signs of intolerance were evident from the first, and the attempt to use local anesthesia was abandoned.

The local anesthesia does away with the danger of aspiration of secretions and the whole procedure is much easier for the patient. In one case an abscess in the lung was cleared out after resection of three ribs, the patient sitting erect in a chair all the time. The total length of the ribs removed ranged from 80.5 to 172 cm., with 134 cm. as the average. There did not seem to be any advantage from including the eleventh rib in the resection. The pains after the operation seemed to be less severe in the cases in which the ribs had been resected subperiosteally. For this reason, operating in two sittings has its advantages. The after-care is extremely important, to ward off aspiration of mucus into the sound lung, and to give stimulants for the heart in case it shows signs of weakening.

The thorax sank in after resection of the ribs, so that the chest on that side was only a half or third of the size of the other half of the chest, as was determined at necropsy in one case with death seventeen days after the operation. Twelve of eighteen patients apparently lost the tubercle bacilli completely from the sputum in the course of a few months. In two or three cases recurring hemoptysis was what called for the operation, but in another case fatal hemoptysis occurred the seventeenth day after the operation. Possibly in this case the reduced ability to cough up the blood may have contributed to the fatal outcome, as the hemorrhage had been small. In the other case, pulmonary embolism the second day was responsible.

THE INFLUENCE OF THE SURGERY OF THE GREAT WAR ON THE SURGERY OF CIVIL LIFE *

JOHN T. BOTTOMLEY, M.D.
BOSTON

It is my pleasant duty to declare open this Victory Meeting of the Section on Surgery—a privilege for which, I need not say, I am deeply grateful to you all. We are gathered here under this significant title to celebrate and commemorate the happy ending of a tremendous struggle in which many of our members took no inconspicuous part. The ending of that struggle came unexpectedly, and it is somewhat unfortunate that the Executive Committee of the section failed to consider that possibility. For, could the committee have had prevision, could it have looked even dimly into the then near future, I am sure that some one far more worthy than I, some one of more active military experience and of greater renown would stand here today as your chairman. Though such an occurrence would have been very probable and though it would have been fitting indeed, yet I can say with truth that no one, soldier or civilian, could stand here with a keener sense of the great privilege of the position or with a truer appreciation of the honor that goes with it.

But a position of prominence means little or nothing at this particular time. We are still too close to the days of peril and struggle, fear and doubt, for honor of position to have any undue weight in our thoughts. We were all cooperators in the struggle, and we are all sharers in the glory not so much of victory as of participation in the fight. Desirable as it is, victory is never absolutely necessary either to honor or to glory. After all, the finest traditions of our art were nobly upheld during the years of stress, and our greatest honor is the one common to each of us, one in which we all hold equal share—that of belonging to a profession which took an active part in the world war and stood openly on the side of right and justice almost two years before this great nation itself officially declared its intention of doing so. That in itself means enduring honor for you and me and our posterity.

We hear it reiterated that this war was fought in defense of democracy. If that be so—and I believe it is—who are more deserving, who are more worthy to be the objects of the homage and respect of the great democratic profession of medicine than those members of it who went forth and voluntarily offered themselves that the world might be a place of sunlight and not of shadow for all that we hold dear?

It is eminently fitting, then, that we give over this meeting to these men of action whose thoughts are born in experience and whose words are freighted with deeds; it is very proper that their ideas should be presented to this most democratic of American medical gatherings. This, I take it, is the real significance of the Victory Session, and in that spirit let us regard it.

It may not be amiss, however, for your chairman to offer as an introduction to the papers a very brief comment on the probable influence that the surgery of the war may have on that of civil life. It is well, perhaps, that this comment should come from one who saw but little active military service, either field or hospital, and whose ideas, therefore, like those of many of you, must arise as the result of deliberation on what is to be read or what is to be heard on the matter in question.

It is true that during the war no entirely new surgical principle was uncovered. But in this fact there is no discredit to surgery, since it is equally true that the long established principles on which surgery rests emerged triumphant from a test, the equal of which they will never meet again. Pasteur and Lister builded for all time. At no period of the war was the truth of the principles of asepsis and antisepsis in danger; their practice, however, was at first rudely shaken. The novelty of it all, the conditions of time, soil, movement, equipment both human and material, the number of wounded, their uneven distribution, the multiplicity, the extent and the severity of their lesions, the virulence and rapidity of their infections seemed about to overwhelm our methods of surgical practice. But organization of our forces, and the application of knowledge already possessed to conditions in the end adequately comprehended, finally resulted in the advent of the two great surgical developments of the war—the practice of débridement (first proposed by Colonel Gale of the British Expeditionary Force and later popularized by Lemaitre) which made possible the successful "primary closure" of contaminated wounds, and the so-called Carrel-Dakin method of treatment, through which successful secondary suture of once infected wounds was rendered feasible.

I am well aware of the arguments urged against the possibility of the successful adoption of the Carrel-Dakin method for general use in the treatment of wounds of war. I know that other antiseptics, such as flavine, dichloramin-T, bismuth iodoform petrolatum paste (bipp), etc., have very justly their warm advocates. I am convinced that the physiologic method of Sir Almroth Wright has its own good points; but nevertheless the testimony of the many men we know

---

* Chairman's address, read before the Section on Surgery, General and Abdominal, at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

whose surgical skill and judgment and whose powers of observation are not open to question compels us to regard the Carrel-Dakin method as one of the great accomplishments of medical science in the recent war. Many of the objections to it as a war measure fall to the ground when its use in civil hospitals is contemplated. It matters not what particular feature of the method is the potent one—whether it be the mechanical cleansing of the wound, the action, antiseptic or physiologic, of the Dakin fluid on the tissues, or the technic of its application to the wounded part—the important fact is its demonstrated effectiveness, when properly applied; of that, I believe, there can be no doubt. It is logical to assume that, as débridement comes more and more into vogue, the need of the Carrel-Dakin method in all its details will be less urgent, since débridement either does away with infection or greatly diminishes its severity.

These, then, are the two most important gifts that the recent struggle brings to the surgeon in civil life. It is obvious that their application will be far wider and more useful in the field of traumatic surgery than in that of the surgery of disease, and this fact will doubtless have a most fortunate bearing, since it will give rise to added interest and efficiency in the domain of industrial and accident surgery, which has not yet had the general attention to which it is entitled and which it is certain to demand in the very near future. We must turn our efforts from the great army of fighting men to the still greater host of industrial workers which crowds daily in and out of our mammoth industrial plants. Here is presented to us a problem similar to that of the war—less intense, perhaps, but surely of wider scope. Here are the wounded, the maimed, the broken, and here opens out to us the field wherein the gift of increased knowledge and experience that war has given us may be best applied. I do not mean to say that the surgery of disease will reap no benefit from our recent experience. I feel that it will. The good may not be great enough to be styled important; but good it will be, even if it mean only laying more emphasis on some phases of our therapy and practice, or lessening the degree of value which we have heretofore ascribed to others.

It is clear that, because of the entirely different conditions obtaining in civil life, the results of our work there must be far better than could be hoped for in the military field. Though the human material hurt and torn in war is drawn from our strongest, our most rugged, our best fitted, yet that advantage is far outweighed by the disadvantages that necessarily accompany modern warfare. The multiplicity of wounds, the delay in the application of treatment, the virulence of the accompanying infection and the extent of the tissue traumatized are seldom encountered in the ways of peace. War has brought into sharp relief the fact that the prompt application of proper treatment is the prime essential to success in traumatic surgery and that lack of it is the great contributor to disaster; it has given certainty to our opinion that mechanical cleansing of a wound has greater basic value than attempts at chemical sterilization; it has given new strength to our belief that the body tissues and fluids possess in themselves tremendous powers of resistance to infection, if only the contaminating agent and the hopelessly traumatized tissue are removed. We knew these things before the war; we apprehend them more clearly now. With this surer grasp and with the hospital conditions that exist today in almost every community in the land, our results in traumatic surgery must be far more satisfactory than ever before. Whether measured in terms of lessened human suffering or increased human efficiency or in those of economic profit and loss, the benefit to the community at large will be very great indeed.

The term "hospital conditions" prompts me to remind you that not a little of the success of surgery in the war was due to efficient hospital organization and to the practical cooperation of the clinicians in the various specialties with the workers at the laboratory desk. Team work accomplished veritable wonders, and we must not permit its great value to go unappreciated by those responsible for the conduct of our civil hospitals. Hartwell and Butler,[1] in an excellent paper read before the American Surgical Association in 1918, called attention to this fact. The activities of all departments of a hospital must be centered in the patient. The chemist, the physicist, the pathologist and the bacteriologist, quite as much and quite as truly as the clinician, must come in touch with the patient and the problem presented by the patient, else the greatest possible service will not be rendered. The results already achieved and those we have good reason to hope for in the plastic surgery of the face and jaw—maxillofacial surgery—are striking examples of what may be accomplished by surgical team work, and it must be noted by all civil surgeons interested in this field. Maxillofacial surgery is not the province of the general surgeon alone, but of the general surgeon working in conjunction with the dental surgeon, the ophthalmic surgeon, the rhinologic surgeon and the aural surgeon. Complete success is attainable only through efficient cooperation, and this lesson must be carried into our civil practice.

PREVENTION AND PRECISION

If we search for the dominant note sounded in the contribution that military surgery has brought us, it may be well expressed by the two terms "prevention" and "precision." What does débridement with its excision of all devitalized tissue, all foreign material, all denuded bone do but *prevent* the development of contamination into infection and make far less probable the dreaded appearance of tetanus, gas gangrene, etc.? What factor in it contributes more to its success than the *precision* with which it is carried out? What does the Carrel-Dakin method accomplish if not the *prevention* of impending infection or, in the event of infection, its spread? What is the keystone of its splendid arch if not the *precise* technic with which the mechanical cleansing of the wound is done, the *precision* with which the solution is prepared, and again the *precision* of its application to the open wound? On what point in the treatment of recent wounds of the joints, the chest and the brain is the military surgeon more strongly insistent than the *precision* and completeness with which the serous membrane lining the cavities must be closed after mechanical cleansing is accomplished? Always the attempt at *prevention* of disaster by *precision* in the application of the means to the end! In all this there is nothing new of principle to the surgeon in civil life. The novelty lies in the overwhelming power of the testimony to its truth.

ACCOMPLISHMENTS OF MILITARY SURGERY

To sum up briefly the accomplishments of recent military surgery which will affect in some degree the practice of surgery in civil life:

It has demonstrated that, even in severe wounds with existing contamination, infection can be prevented or controlled. Tetanus has practically been banished because of the preventive quality of the antitoxin. Treatment by magnesium sulphate and phenol (carbolic acid) has been definitely put aside. The wound conditions favoring the development of gas gangrene are recognized, its pathology is known, the earliest signs of its presence are tabulated and, as a consequence, its treatment is now on a more scientific and successful basis. There are promising indications that an effective antitoxin against it may be developed. There is no longer any question as to the proper treatment either in peace or in war of penetrating wounds of the abdomen. The contention of the civilian surgeon has been upheld. Many of our doubts in chest surgery have vanished. The need of complicated pressure apparatus has gone with the establishment of the fact that without it the pleural cavity may be opened freely and the lung handled with no undue danger. The final report of the studies on empyema, which was rampant in our war camps, will place the treatment of that complication in a clear light. Evidence that is convincing has established beyond doubt the position of those who in prewar days asserted that the synovial membrane had strong power of resistance to infection and that drainage of joints recently wounded is not only unnecessary but often harmful. The factors entering into the production of shock and the details of its treatment have been so vividly delineated for both the public and the profession that no surgeon who has to do with the great industries in which severe injuries are common can afford to neglect provision for the prompt and efficacious treatment of the shock that may accompany them. The treatment of fractures has been stabilized by the standardization of splints and other apparatus for immobilization. The use of plaster of Paris has been very greatly supplanted by that of the standardized splints and apparatus. Many problems in connection with the transplantation of bone will be cleared up. Methods of transportation of the injured will be improved. Decision will be forthcoming in many bothersome questions with relation to the surgery of the nerves, such as tubulization by fascia or by pieces of vein, and anastomosis by autografts or by nerve splitting. Indirectly, surgery will benefit through the stronger spirit of discipline, the more rigid practice of economy, and the more efficient measures of cooperation that will obtain in our civil hospitals.

A WARNING

A word of warning to the young medical men who entered military service and who in the discharge of their duties have had some surgical experience: Do not let the story of the days that followed the closing of the Civil War be repeated. Do not imagine that the experience acquired in military surgery, unless it be based on or followed by a thorough surgical training in a civilian hospital, warrants any man in assuming that he is an able surgeon or that he has any license to regard or conduct himself as such. I trust that these words are spoken unnecessarily; but with the experience of the past in mind, it seems wiser to say them unnecessarily than to leave them unsaid.

RESTORATION OF WOUNDED

No story of the medical aspect of the war will be complete that does not take into account the restoration and reeducation which we owe as a duty to the 80,000 broken and maimed boys that the war has given back to us. Full consideration must be given to the numerous cases of chronic osteomyelitis, of injury to peripheral nerves, and of chronic suppuration that will long people our military hospitals. We are yet too close to the days of battle to have a proper perspective of the remote influence of these conditions on civil surgery. Only when based on the study of end-results can a true evaluation of the worth of any surgical procedure be had; for that reason, it is obvious that some conclusions can as yet be held only tentatively—a point that deserves more emphasis than can be given to it in so brief a communication as this.

PHYSICAL TRAINING

Quite as interesting a problem is that suggested by the fact that in the state of Massachusetts more than 40 per cent. of the men called in the first draft were rejected as physically unfit and that thousands of boys from the country at large were accepted and sent overseas only to be found unsuitable for active service because of their physical defects. Such a condition should not obtain in this country. To whom will the nation look, if not to us, for the plan of some sort of physical training that will prevent the continuation of such an undesirable state of affairs? Less could not be asked or expected of a profession that has always given proof of its firm belief in the worth and sacredness of human life and in the value of bodily health and soundness.

THE CORRELATION OF LABORATORY AND CLINICAL TEACHING IN SURGERY

ADRIAN V. S. LAMBERT, M.D.
Associate Professor of Surgery, Columbia University, College of Physicians and Surgeons
NEW YORK

No one can come into close contact with medical students without becoming impressed by the constant complaint that the laboratory subjects are not taught from the practical standpoint. Many of the students who have just completed academic courses in which much that has occupied their time has, to their minds, had no direct economic value, enter the professional schools with a determination to employ every moment to best advantage. They are restive under the restraints of the first two laboratory years. For example, many feel that much time in anatomy is wasted, and unfortunately they are too often strengthened in this opinion by the expressed views of some of the less thoughtful teachers in the laboratory and clinical branches. It is the failure to demonstrate to the student the real value of the subject taught, and the failure of the teachers to appreciate the importance of the subject-matter itself, which causes discontent. In consequence, there is danger that the teaching in the laboratory branches may depart from the well established and correct method of presenting the subject-matter so that the student learns by personal observation, always a slow, laborious process, but the only one which rests on a permanent, firm foundation.

On the other hand, no such complaint is heard of the clinical branches. Any and every subject, however presented, is considered worthy of profound study if it only deal with a condition to which the human flesh is heir; but oftentimes the teaching does not follow the more advanced and best recognized methods, and the students are graduated with a theoretical knowledge of these subjects, dependent on the faculty to memorize the written word, and quite untrained in powers of observation, deficient in ability of deduction from facts gained through the impressions of their five senses, and incapable of expressing in the English language the results of such mental processes as they may possess.

The teaching of surgery has very largely depended on lectures to fairly large groups of students. These lectures were of two kinds, the theoretical, and the clinical lecture, or demonstration. They differ from one another only slightly. In the one a subject is arbitrarily chosen and talked about; in the other the patient determines the subject. Such teaching had great advantages when there were few good textbooks or adequate monographs available to the student, since it enabled him to hear the views of the leaders of the profession; but today, with the many books and widely circulated and readily accessible magazines, these presentations to large groups are antiquated. The theoretical lecture may still serve three useful purposes: first, to arrange and correlate facts for the student into a well ordered, well balanced whole (but even this could probably be accomplished better by a printed article); second, to settle disputed points on subjects about which there exists an honest difference of opinion among the leaders of surgical thought (the student being incapable of weighing the evidence for reaching a decision, and thus a discussion by a learned teacher often proving enlightening); and third, to impart new facts which the student could learn only through wide reading of current literature, for which he would not have the time. Except for these purposes lecturing should be abandoned.

Surgery lends itself well to the modern principles of teaching, which, if followed, would result in a decided modification of the method of conducting courses hitherto given in our schools. The student must gain his knowledge through the use of all his senses, and have the acquisition take place over a long period of time, with the repetition of those impressions occurring without a sense of fatigue. We must associate the various stages of a disease by constantly rejuvenating past memory pictures in connection with present conditions, thus coordinating the widely differing appearances in the course of a disease, and must also demonstrate the connection of cause and effect. We must, therefore, be able to control our demonstration material. This is possible only by the employment of animals. With these purposes in view we have planned the course at Columbia University as follows:

During the first half of the second year a series of demonstrations are given to small sections of the class, in which they study the application of physiology to the various surgical problems that they will meet later. Normal functions are presented and considered from the clinician's standpoint. For example, the recent work of Graham and Bell[1] on the mechanics of the thoracic cavity and of pneumothorax is based on the application of physics to physiology, and this is exhaustively demonstrated and the problem explained in detail.

In this way atmospheric pressure, negative pressure and a vacuum become real entities, things that will have to be reckoned with in the treatment of disease, and they immediately cease to be intangible, indefinite somethings, dimly associated with mercury columns in glass tubes, Sprengel air-pumps, glass bell jars, and 15 pounds to the square inch. These should be demonstrated on living animals, their importance in connection with thoracotomy should be emphasized, and the student should gain a knowledge of them by employing all his senses. Thus he will form a lasting memory picture to be used when he requires it in connection with his study of empyema or other diseases of the pleura and lung. Other subjects taken up are the series of classical demonstrations by Cushing[2] of the effects of intracerebral pressure on the blood pressure, pulse and respiration. The nervous system is further studied by repeating Sherrington's[3] epoch-making experiments of unipolar stimulation of the motor cortex of the brain, and, in addition, the confirmation of cortical localization by extirpation of portions of the cortex of the ascending frontal convolution.

The peritoneal cavity is considered from the standpoint of absorption and drainage, and the properties and peculiarities of the peritoneum and omentum are shown, especially their reaction to foreign bodies. The results of the brilliant and illuminating work of Cannon[4] on intestinal peristalsis and stomach function, as shown by fluoroscopy, is utilized to give the student a basis for knowledge of visceral function. In these demonstrations the students act in turn as assistants.

In the second half of the second year the student commences his consideration of true surgical conditions. A simple wound is chosen. He makes such a wound on an animal and watches it heal. From time to time a section of such a wound is taken and studied under the microscope. He thus associates the histology with the extremely important element of time. He sees what changes take place in the blood clot, he learns when the fibroblasts first appear, understands the formation of granulation tissue, and thus gains a rational conception on which to base the after-care of such a lesion. Similar wounds on patients from the clinic are then demonstrated, a few representative cases being shown, and from the many microscopic slides, laboriously collected for years past by Dr. W. C. Clarke, appropriate ones are demonstrated and thus the histologic changes are associated with the clinical appearance. At first a simple incised wound of the skin and subcutaneous tissue is studied, and later the healing process in wounds as it occurs in the various other tissues, muscles, aponeuroses, bones, intestines, liver, spleen, kidneys, etc., is demonstrated. After this simple healing process is learned, the changes or accidents incidental to healing are studied in the same manner; for example, healing under a scab, pyogenic infections, specific infection, etc. In every instance the student either makes the lesion on an animal or he sees it made and then watches that same lesion day after day and studies and observes its phases and changes as they occur. This is supplemented by lantern slide demonstrations of similar lesions in human beings, and the study of microscopic slides.

Physiol. **6:** 251-277; Peristalsis Segmentation and the Myenteric Reflex Am. J. Physiol. **30:** 114-128.

In the third year the study of special surgery begins. No attempt is made to cover the entire field. All we hope to do is to take up a few of the most important subjects, and to demonstrate the correct method of learning about a disease. We trust to the student by his reading to inform himself on the myriad of others. We educate him so far as to be able to study surgical literature intelligently. We do not attempt, because we believe it impossible, to give him an encyclopedic knowledge of surgical affections.

The following subjects have been selected because of their importance and of the possibility of demonstrating them on animals: peritonitis, appendicitis, diseases of the gallbladder and gallducts and abscess of the liver, diseases of the pancreas, acute ileus, hydronephrosis, abscess of the kidney, diseases of the ductless glands, empyema, and osteomyelitis.

Each subject must be presented in a special manner, and an intimate knowledge of how each condition develops in the animal is required. The choice of the species of animal best adapted to the development of the disease to be demonstrated is an important element of success. The time element is such an important factor that a careful curriculum of the student's time schedule must be obtained. This has been made possible at Columbia by a cordial cooperation of the faculty and the dean. The surgical course is arranged so that three mornings from 9 o'clock to 1 are available—Tuesday, Wednesday and Friday.

Each subject is studied in quite the same manner. The class is divided into groups of ten, an instructor is assigned to each group, and the entire class is taught at the same time. As an example I shall explain in detail how appendicitis is studied.

There is an anesthetized dog for each group of ten students. The instructor, assisted by one of the class, opens the abdomen under the rigid asepsis of modern technic, delivers the cecum into the wound and places a purse string suture about the base of the cecal pouch in such a manner as not to interfere with its blood supply, and yet to isolate that portion of the intestinal canal from the rest and thus to prevent anything introduced into its lumen from passing into the colon. He then makes an opening in the pouch 0.5 cm. long and introduces a small gauze tampon saturated with a pure culture of *Streptococcus hemolyticus*[5] into its lumen, and scarifies the mucous membrane lining with a scalpel. He then closes the opening with a purse-string suture and drops it into the abdomen and closes the abdominal wound. The student assistant then writes in the history a description of the procedure. As we have about ten sections in our classes, we have ten animals that receive identical treatment.

The students are instructed to watch the animals in their cages in the hospital and the assistant at the operation records notes as to changes in the dog's condition, keeps a temperature chart and does a daily blood count. After forty-eight hours, four of the animals are killed and a necropsy is performed immediately; we thus have one animal for each group of twenty-five men. The condition found at this time will be a well established florid inflammation in the cecal pouch, which will be wrapped about with omentum greatly swollen and inflamed, and in addition a well marked local peritonitis, or at times a localized abscess. The student thus sees the cause and effect. He records a memory picture of the reaction of the peritoneum to bacterial invasion. Four of the remaining animals are operated on under strict asepsis, a student acting as assistant. The cecal pouch is removed and a rubber tube drain is placed down to the site of the necrosed tissue in two of the dogs, and the other two are sewn up tight. On the following day, seventy-two hours after the first procedure, the two remaining dogs that have not been operated on are killed and necropsies performed immediately afterward. At this time a widespread, diffuse, and, at times generalized peritonitis of a virulent character is demonstrated. The dogs that have been operated on are also killed at this time, and the adhesions about the drainage tubes, the recovery of the remainder of the peritoneum, in fact, the effect of removal of the focus of infection and the good results of drainage are demonstrated. The outcome of the treatment in the animals in which the focus of infection was removed and the abdomen immediately closed will depend on the type of peritonitis present at the time of the operation. At times perfect recovery of the peritoneum may be shown, while in other cases the peritonitis has progressed and become diffuse and generalized.

During this entire period of observation the student makes blood counts and keeps the history, recording appropriate notes. At the necropsy he takes bacterial smears and cultures, writes a description of the findings and takes portions of the organs and tissues, which are sectioned and mounted, and which he studies at a subsequent exercise. A large bulletin board divided in squares is placed in the laboratory, and each space is devoted to a subject or disease. Here is posted by the instructors, from time to time, lists for collateral reading, any special features to be noted in the postoperative animals in the hospital, and such other data as may be pertinent to running the course. After these demonstrations, a conference is held on appendicitis, and the subject is discussed from the standpoint of its incidence in man, the student having read some work assigned to him covering the subject. Each subject is presented in a similar manner, some requiring weeks and, in cases of bone lesions, months for their complete development. During this period the student watches the animal, makes notes and records observations, and we believe this time element is one of the most important features of the method. It impresses on the student's mind the idea of the course of a disease. It gives him the first inkling of the difference between the word acute and chronic.

In addition to these subjects there are a number of very important ones which must also be taught, but which do not lend themselves well to animal demonstration. These are neoplasms of all kinds, affections of the female mammary gland, affections of the stomach and intestines. In these we have adopted a different method of presentation. The class is divided into groups of ten men, and conferences are held in which the students carry on the exercise as much as possible under the supervision of the instructor, correcting one another and answering each other's questions. Coincident with these conferences an attempt is made to demonstrate cases which illustrate the disease under discussion, and pathologic specimens of the various lesions are shown.

---

[5] From experience we have found that more uniform results are obtained with this organism than with others. We have employed Bacillus aerogenes-capsulatus and Staphylococcus aureus, but our results varied widely and for demonstration purposes were not sufficiently uniform.

A course in fractures of the bones of the extremities is managed by combining clinical work on patients by small sections of students with theoretical conferences. Cases are shown the student and he follows them from beginning to end, week after week. On other days conferences are held and the subject discussed at length. Here a textbook is employed and we attempt to regulate the student's reading, to train him to connect his reading with his clinical experience. In this course we have a sharp contrast with the animal experimental course. Here we emphasize the importance of enlarging our store of facts by study of the written word, and show how knowledge acquired in this way may be made use of at the bedside or in the dispensary. We consider fractures of the bones of the extremities particularly well suited for this purpose, as the history is usually clear cut and pertinent as to details, the symptomatology is direct and striking, and the physical signs are demonstrable and readily appreciated, while the treatment, being mechanical, appeals to the simple, untutored intelligence of a beginner. No attempt is made to demonstrate every form of fracture or everything about any special kind of fracture, but a sufficient number of cases are demonstrated and followed to make the student familiar with changes common to fractures, and so in his studies his reading may be carried on intelligently.

A course in minor surgery is also given—two days a week for the entire year. The class is again divided into small sections for its clinical work, and twice a week a limited number of cases are studied. One case is taken by two men, who work it up carefully in all the details and present it to the section, when an informal discussion of the case is carried on, the many details presented by the student being commented on by the instructor. The simpler class of cases is chosen at first. The object being to drill the student in methods of examination, history taking, clinical pathology and then to arrive at a diagnosis and to outline and carry out the treatment, minor operations are performed before the student, and bandages and dressings are applied by him.

At the end of the third year, during the last eight weeks, the entire class returns to the dissecting room and takes up the study of anatomy of the extremities by dissections, demonstrations and conference, during which period the course in orthopedic surgery is begun and the study of joint anatomy and function, and the application of muscle anatomy to muscle function, are studied. Clinical lectures and demonstrations to small groups are given twice a week. These are correlated with the work in the dissecting room in order to bring out the intimate connection between anatomy and orthopedics and fractures.

In the fourth year the class is divided into small groups and bedside instruction is given. The student spends all day in the hospital, and so is able to study the cases before operation. He may be present at the operation and then follow the case during the postoperative course. He has the opportunity of examining the pathology of the specimens removed and of doing the clinical pathologic tests. During his stay in the hospital he is given a short course in cystoscopy, during which he has the opportunity of examining bladders through the cystoscope, and by lantern slides he is shown examples of the commoner lesions.

Once a week patients presenting postoperative cases are taken to the amphitheater and the treatment is discussed before the entire class, the wounds are dressed and special stress is laid on the question of drainage, abdominal, thoracic, and of the soft parts. As many complications are shown as occur on the service; in fact, the cases which do badly are taken up at these conferences and freely discussed.

In this course a determined effort has been made to depart from the old theoretical lecture or large clinical lecture, which differ from one another only in that a patient serves as a text in the one, while in the other the subject is chosen beforehand. Here the ear is about the only sense which is appealed to, possibly to a slight extent the eye, but smell and feeling are not called on to register memory impressions and much of the value of the study of diseases is lost.

An attempt has been made to fashion the teaching of surgery along the lines of modern ideas in the psycology of learning, to conform to the three laws of readiness, exercise and effect, so ably expounded by Thorndike,[6] who, in his analysis, has so convincingly demonstrated that synapses between neurons are not only the anatomic but indeed the physiologic basis of behavior, and that these may be strengthened or weakened according to the above laws.

A REPORT OF A WARD EPIDEMIC OF MENINGOCOCCUS MENINGITIS

GEORGE R. WILKINSON, M.D. (Baltimore)
Lieutenant, M. C., U. S. Army
CAMP JACKSON, COLUMBIA, S. C.

During the present emergency an exceptional opportunity for the study of acute infectious diseases has presented itself. Many things have come to light since the well equipped laboratory and the patients have been brought together under military control. The study of meningococcus meningitis has held one of the central places of interest, not only on account of its frightful course when untreated, but also because of the progress that has been made in its study. The old conception of the disease as being primarily an infection of the meninges is now untenable in the face of recent laboratory and clinical findings. The disease may be better understood by regarding it as a bacteremia. This change of view has led to a more effectual method of treatment, that is, the combined intravenous and intraspinal administrations of serum.

In times past so little attention has been paid to the infectious nature of the disease that the patients were taken care of in a general medical ward. In the military establishments, however, great stress has been made on the infectious nature of meningococcus meningitis. The cases have been carefully isolated, contacts watched, ward attendants instructed to wear gowns and masks and a careful search for carriers made. The carrying out of this program has entailed not a little expense to the government. The report of a ward epidemic, though very small, is of considerable importance in showing the real practical necessity for the wise precautions taken to prevent the development and spread of the disease.

---

[6] Thorndike, Edward Lee: Educational Psychology, Ed. 2, New York, Teachers' College, 1910.

REPORT OF WARD EPIDEMIC

Sept. 27, 1918, Ward E-1, a general medical ward, was converted into a pneumonia ward to accommodate the increasing number of pneumonia cases that developed during the epidemic of influenza. The ward contained thirty-two beds; the prescribed amount of air space and the cubicle isolation system were employed. There was practically no porch space, since the side and end porches were used as covered ways, thereby making the ward darker than usual. Additional nurses and corps men were assigned to the ward. September 27, sixteen patients were admitted and by the 30th the ward was full.

October 7, at 7 p. m., ten days after the conversion of the ward, one case of meningococcus meningitis developed, followed by three the next day and two on the day following. The last case was diagnosed, October 8, at 9 p. m., thus making six cases to develop within a period of fifty hours. This group will, for convenience, be called the bed series. October 18, at 11 a. m., and October 21, at 8 a. m., respectively, two more cases developed within forty-five hours of each other. The two cases will be called the ambulant series.

DATA IN EIGHT CASES OF MENINGOCOCCUS MENINGITIS

		Signs Establishing Original Diagnosis									Later Confirmation			Treatment		
Case Number	Days in Ward	Erythematous Rash	Petechial Spots	Psychic Changes	Headache	Nausea and Vomiting	Stiff Neck	Increased Reflexes	Asymmetrical Reflexes	Lumbar Puncture	Lumbar Puncture	Blood Culture	Type of Organism	Intraspinal Serum	Intravenous Serum	Result
1	10	+	+	+	0	+	+	+	+	+	+	0	IV	153	370	Recovered
2	10	+	+	+	+	+	0	0	0	+	+	+	..	...	100	Died
3	7	+	0	+	0	0	+	+	+	+	+	0	..	145	634	Died
4	7	0	0	+	0	0	0	0	0	+	+	0	..	120	365	Recovered
5	13	0	+	+	+	0	0	+	0	+	+	0	..	20	100	Died
6	10	0	+	+	0	0	0	+	+	0	+	0	..	300	1,250	3 relapses, recovered
7	18	+	+	+	+	+	+	0	0	+	+	+	IV	165	205	Recovered
8	26	+	+	+	0	0	0	+	+	0	+	+	IV	60	370	Recovered

Case 4 was transferred to a convalescent ward, where he developed the disease. Case 8 developed pneumonia in the ward September 27.

After the development of the first case, all patients were examined for suggestive signs. As soon as any one thing was found, a tag, with the symptoms written on it, was attached to the foot of the bed and the suspects were carefully watched. All the patients in the ward were examined four times a day until two weeks had elapsed after the first case occurred. The ward attendants were instructed to look especially for rashes, changes in mental attitude, stiff necks, nausea and vomiting. The ward was quarantined. All attendants and ambulant patients wore gauze masks. As soon as a positive diagnosis was made, 1 c.c. of antimeningococcus serum was given subcutaneously for desensitization, and the patient immediately transferred to the meningitis ward.

A search for the source of the infection disclosed the fact that none of the unfortunates had, to their knowledge, been exposed by contact to any meningitis prior to their admission to the ward. Throat cultures were immediately made of all the ward attendants, and patients, three cultures each for the attendants, and two each for the patients. October 8, the day following the outbreak, while preparing a patient for a lumbar puncture, one of the newly assigned corps men displayed an unusual amount of intelligence in the manipulation of the patient. On being questioned, it was learned that he had himself been a victim of the disease during the preceding winter and had worked as an attendant in the meningitis ward for some time afterward. The only positive culture found, from all those taken, was that from the corps man mentioned above. This organism was agglutinated by polyvalent serum, but unfortunately was not typed. The carrier suspect was immediately transferred to the meningitis ward, where treatment was instituted to rid his nasopharynx of the organism. Further attempts to find a positive culture in this person were unsuccessful.

The patients of the bed series were confined to bed during their entire stay in the ward, the only contact being with the ward attendants and a very few occasional visitors, who had to do only with the particular patient they came to see. Patient 2, a nurse, who is being counted in the bed series, was on duty for ten days in the ward. She came in contact with the night force, as it was a habit of the day nurses to stay on duty after hours, during the emergency, until they were actually ordered off the ward by the ward surgeon. It is fair to count this case in the bed series, since this patient went off duty at 12 (noon), October 7, and died at 10 o'clock the following morning, with the fulminating type of the disease. The two patients in the ambulant series were up and about during the time when the first group sickened with the disease and were thereby exposed to the carrier and the other patients. The patients were scattered all over the ward, only in two cases occupying adjacent beds. All the cultures that were successfully typed were of the same group; one case, however, in which both the blood and spinal fluid were typed, showed a difference in type. Only three cultures attained sufficient growth for typing.

PROBABLE PERIOD OF INCUBATION

A slight amount of information as to the period of incubation of this disease is shown by the fact that each group of cases developed within a period of fifty hours of each other, the bed patients coming on from seven to thirteen days after exposure to the carrier, and the ambulant patients developing the disease from eighteen to twenty-one days after exposure to the carrier, or from nine to fourteen days after exposure to the other patients. This would indicate that the incubation period is between one and two weeks. It is important to note that the disease in the two patients in the latter group ran a much milder course; this probably means that these persons contracted the disease from the bed patients, thus lending weight to the doctrine of attenuated virulence by passage through another individual.

CONCLUSION

1. A ward epidemic of eight cases of meningococcus meningitis is reported.
2. The tracing of the epidemic to a carrier is reported.
3. The carrier presents a really important problem and must not be disregarded.
4. The importance of observing contacts is emphasized.

5. A suggestion is made that the possible period of incubation of the disease is from seven to fourteen days.

6. Fourteen days is recommended as a quarantine period for meningitis contacts.

EMPYEMA AT BASE HOSPITAL, CAMP SHERMAN, OHIO

W. T. DODGE, M.D. (Big Rapids, Mich.)
Major, M. C., U. S. Army; Chief of the Surgical Service, Base Hospital

CAMP SHERMAN, CHILLICOTHE, OHIO

On entering service at any of the base hospitals of the United States in the winter or spring of 1918, one was immediately impressed by the prevalence of disease due to transmission of infections through the medium of secretions from the mouth and nose. The most serious of these infections was pneumonia, and the most serious complication of pneumonia was empyema. Men of long professional experience were impressed with the idea that the principles acquired in civil practice concerning the treatment of empyema were not applicable to the type of disease encountered in military camps. There was often considerable difference of opinion between members of the surgical service as to the proper methods of treatment, and still more often differences in opinion between the medical and the surgical services as to how these cases should be managed. This condition of things existed at the base hospital, Camp Sherman, Ohio, owing to the fact that the surgical service at that time believed in early operations; but so many of the patients died soon after operation that the medical service discontinued transferring patients, and, in some instances, went to the other extreme and delayed operation too long.

In October, 1918, when the influenza epidemic was at its height, it became apparent that it would be followed by many cases of empyema, and, as the final decision concerning the surgical treatment to be employed would devolve on me, I undertook the study of the cases treated prior to July 1, 1918. This study disclosed that fifty-three patients had been treated in the surgical service, with twenty-three deaths; simple thoracotomy had been performed forty-nine times, and rib resection four times.

RESULTS OF OPEN DRAINAGE TREATMENT

All were treated with open drainage and the instillation of surgical solution of chlorinated soda (Dakin's solution), under the supervision of a surgeon, eminent in civil life, who was fresh from a course of instruction at the Rockefeller Institute. These patients were sick for a long time, and eventually the use of Dakin's solution was discontinued, and instillations of 2 per cent. formaldehyd solution in glycerin (containing approximately 0.07 per cent. of absolute formaldehyd) were substituted. Immediate improvement took place, the septic condition disappeared, the patients put on flesh, and it was confidently expected that they would speedily recover. This group of cases formed the basis of the article by Lieut.-Col. J. G. Sherrill,[1] published in April, 1919, but written in the summer of 1918, and at that time submitted to this service for review. Sherrill was an accurate observer, and his conclusions were justified by the condition of the patients at that time and were indorsed by all of us. Subsequent experience with this series of cases, further study of bacteriologic findings, and experience in the use of chemical antiseptics, including formaldehyd glycerin solution, in another series brought us to a far different conclusion. The query naturally arises concerning the numerous reports from other hospitals on this subject as to how many of them would have retained their reported opinions had they reserved their reports until the completion of a given series of cases. When Sherrill was transferred from this hospital, all the patients who had been under his care had apparently recovered.

Fifteen patients recovered under the use of Dakin's solution and were discharged. Fifteen remained under treatment after the change was made to formaldehyd glycerin solution. The wounds closed in four patients who were returned to duty and not heard from again at this hospital. In five of the remaining eleven, the wounds also closed and these patients were discharged, but in a few weeks were readmitted with reopened sinuses leading into the pleural cavity. During August, these eleven patients were subjected to costatectomy, after a study of their chests in the roentgen-ray laboratory. This was done by passing a small catheter through the sinus and introducing a solution of potassium iodid. This procedure outlined the cavity as viewed through the fluoroscope. In each case large quantities of partially organized lymph and pus were found in the pleural cavity. One of the patients died a month after the operation from acute infection of the opposite lung. Three had connections between the bronchi and the pleura and were transferred to a general hospital, where two recovered and one died from pneumonia in October, which made the final results twenty-five deaths in fifty-three cases. Two patients are still in the hospital after more than a year, and each presents a small sinus through the thoracic wall. Each has had several operations for the purpose of collapsing the chest wall, and at present is convalescing and will soon be ready for discharge.

TABLE 1.—MORTALITY BASED ON TIME OF OPERATIONS

		No.
Deaths:	Those operated on prior to the eleventh day after development of pneumonia	7
	From twelve to twenty-four days	5
	From thirty-one to fifty-five days	11
Recoveries:	Tenth day	1
	Eleventh day	1
	Twelfth to twenty-fourth day	19
	From twenty-eighth to sixty-first day	10

The lowest mortality occurred in the period in which operation was performed from within twelve to twenty-four days after the development of pneumonia; and in the period exending beyond the thirtieth day, the mortality was approximately 50 per cent.

The bacteriologic findings in this series of cases were pneumonia from pneumococcus Type IV. In the pleural fluid a nonhemolytic streptococcus was found in the majority of the cases. Five presented *Streptococcus hemolyticus* in the pleural fluid.

RESULTS OF TREATMENT BY ASPIRATION

The medical service experimented with aspiration and instillation of formaldehyd glycerin solution, and a few members of that service in May and June, 1918, were enthusiastic concerning this treatment. Two patients were reported as having recovered without other treatment. Since that time the medical service has experimented with simple aspiration, repeated at intervals of three days with results quite as satisfactory as those obtained in the use of formaldehyd glycerin. The chief of that service informs me that he is now fully satisfied that when pus forms it should be evacuated from the pleural cavity under the same surgical rules that govern its treatment in other regions of the body.

---

[1] Sherrill, J. G.: Observations on Empyema, Surg., Gynec. & Obst. 28: 371 (April) 1919.

In arranging for the treatment of prospective empyemas early in October, 1918, conferences were held with the chief of the medical service and with the members of the surgical service who had had experience in handling the disease in this hospital during the previous year. A course of procedure was agreed on, and in subsequent proceedings the two services operated in harmony. It was decided that in the early treatment, aspiration and instillation of formaldehyd glycerin solution be given a fair trial. It was also agreed that the chest should not be opened in the early stages of the disease. The use of the aspirator in our first cases soon convinced us that this was not an entirely harmless procedure. Several patients with chests full of fluid and with quiescent pneumonia developed severe pain immediately after removal of seropurulent fluid with the aspirator. In one case the pneumonia again became active. The pleuritic fluid did not reform, and the patient died. The instillation of formaldehyd glycerin solution was found to be without beneficial effects. In one of the early cases a procedure used at Walter Reed General Hospital was adopted, that is, the introduction of a small drainage tube through a cannula, and instillation into the pleura of Dakin's solution. This patient did badly, and after five days rib resection was performed, after which he recovered slowly, requiring two secondary operations. We then limited the use of the aspirator to a diagnostic purpose, and after the fluid became purulent opened the chest by resection of one rib and introduced two large drainage tubes. No irrigations or instillations into the pleura were made for ten days after the operation, and in many of the cases were not made at all.

METHOD OF OPERATING

The area was infiltrated with a 0.25 per cent. solution of procain: first, the subderma and then the muscle over the selected rib, and finally, the periosteum covering the rib. In this manner a portion of the rib was removed and drainage tubes were introduced as easily as thoracotomy could be performed and without distress to the patient.

BACTERIOLOGIC FINDINGS

All the patients had bronchial pneumonia of Type IV following the influenza epidemic of October, 1918. All were very sick for a long time with a severe general infection, and in all of the fatal cases the patients had serious complications, or rather infections involving other than the pleural cavity. Many of the patients were considered to be in a hopeless condition at the time of operation, but made excellent recoveries.

COMMENT

It thus appears that the severity of the disease and the tendency to chronicity bore no relation to the variety of organism found in the pleural fluid. In no case was operation performed earlier than seventeen days after the onset of pneumonia, and the average period was twenty-five days. In no case were instillations into the pleural cavity permitted during the first ten days. Cases presenting profuse and offensive discharge were then treated with instillations. Dakin's solution was used in five cases; formaldehyd glycerin solution in five cases, and simple flushing with 50 per cent. solution of glucose in a considerable number. This procedure was highly regarded for some time, and it gradually supplanted the use of formaldehyd solution and Dakin's solution.

TABLE 2.—RESULTS OF TREATMENT

	No.
Number of cases developing in this camp from July 1, 1918, to April 1, 1919	71
Number treated immediately by open drainage	68
Deaths	18
Recoveries with full lung expansion without secondary operations and returned to duty prior to April 15, 1919	36
Convalescent without secondary operation	2
Number subjected to secondary operation	10
Convalescent after secondary operation	4
Ambulatory patients presenting cavities of various sizes in the pleura	7
Bed patients ill with complications	1
*Cases treated primarily by the Mozingo method, subsequently by open drainage	3

*These are now ambulatory cases but have large suppurating pleural cavities.

Ward 3 was devoted entirely to patients with empyema, and the overflow was sent to Ward 6. All the experimental work with antiseptic solutions was done in Ward 3. In Ward 6 all patients presenting a high temperature were irrigated with physiologic sodium chlorid solution. Eighteen cases were treated in Ward 6, and it is an interesting fact that no death occurred in that ward.

Eventually the use of all irrigating solutions except that of physiologic sodium chlorid solution was abandoned in Ward 3. The ten patients treated with Dakin's solution and the formaldehyd glyerin solution were found after several months to have partially collapsed lungs and cavities of considerable size. They were subjected to secondary operations, and in each case a very thick layer of organized lymph was found holding the lung in a state of partial collapse. Ribs were removed and numerous incisions were made across the confining layer of lymph, and four of the patients are now convalescing, and the others are ambulatory and in good physical condition.

TABLE 3.—ORGANISMS FOUND IN PLEURAL FLUID

	No.
In fatal cases:	
Pneumococcus Type IV	8
Hemolytic streptococcus	6
Nonhemolytic streptococcus	1
Staphylococcus	1
In patients that recovered:	
Pneumococcus Type IV	19
Hemolytic streptococcus	10
Nonhemolytic streptococcus	3
Staphylococcus	2
In patients still in hospital:	
Pneumococcus	5
Hemolytic streptococcus	6
Nonhemolytic streptococcus	1

In connection with the consideration of the use of Dakin's solution in empyema I quote the following from a private letter received from Major F. C. Warnshuis, chief of the surgical service of Base Hospital No. 99, at Hyres-Var, France, who in the summer of 1918 was attached to this service:

> I thought I would be through with empyema when I left Sherman, but it seems *not*. Yesterday we received 260 surgical cases, among which were eleven active empyemas. These patients had been operated on from four to ten weeks before, and were about like the bunch we cleaned up at Sherman. There were in addition five cases healed. In going over their histories today I find that the eleven cases had been treated with Dakin's, while the five healed cases had not, so you see it is the same old story; and what gets *me* is that they can't see the harm done by Dakin's when introduced into the pleural cavity. I hope you comment strongly on the misuse of Dakin's solution in the treatment of empyema. I consider it a crime to use it.

Dec. 21, 1918, we received a report of the method adopted at Walter Reed General Hospital by Capt. A. E. Mozingo which he calls the "closed method." This consists in introducing a small rubber tube into the pleural cavity through a cannula or by puncture through the chest wall with a pair of forceps, evacuating fluid by suction with bulb syringe introducing Dakin's solution, withdrawing it again by means of a bulb and repeating this procedure at intervals of two hours for several days, after which formaldehyd glycerin solution is instilled through the tube after the irrigation with surgical solution of chlorinated soda. In the interval the tube is closed by shut-off, and no air at any time is permitted to enter the pleura. After obtaining the details of this treatment we received three new cases. We adopted the treatment in each case on the ninth day after the onset of pneumonia. All the patients were very sick and had large accumulations of seropurulent fluid, which was reported by the laboratory to contain hemolytic streptococci. In the first case pneumonia developed, December 19. Thoracotomy by the closed method was performed, December 28. Irrigations with surgical solution of chlorinated soda every two hours were continued for seven days, after which irrigations were done twice a day with instillations of formaldehyd glycerin solution until February 2, when the fluid was reported to be sterile and the thoracic opening closed spontaneously a few days thereafter. The second patient entered the hospital, December 4, with measles. Secondary pneumonia developed, December 18. Thoracotomy by the closed method was performed, December 27. The same after-treatment followed as in other cases, and the thoracic wound closed spontaneously, January 29.

The third patient developed pneumonia, January 5. Thoracotomy by the closed method was performed, January 14, and the wound closed spontaneously, January 25.

At this period we felt highly elated over this method of treatment, and hoped that a real advance had been made in the handling of this disease. The roentgen-ray laboratory reports were not reassuring, as each examination revealed gradually increasing amounts of fluid in the pleura, and no evidence was found that the collapsed lungs were expanding to fill the space. One month after the closure of the openings in the thoracic wall, the fluoroscope disclosed fluid in each case up to the level of the third rib. The aspirator revealed the presence of pus, which in one case resulted in a culture of hemolytic streptococci. In two cases, culture was negative. Rib resection was performed in these three cases, and very large cavities were discovered. The same firm-appearing layer of organized lymph confining the lungs in compression, as had been found in all the other cases treated by instillation of irritating antiseptics, was found. Negative pressure had been continuously applied to these cases by creating a partial vacuum in the cavity, commencing nine days after the onset of pneumonia, thus probably cutting short the infecting process, yet we were confronted with larger cavities than we had previously been called on to cope with in cases treated by open drainage. Many writers have claimed that Dakin's solution dissolves inflammatory lymph and thus hastens lung expansion. I have never seen any evidence of the correctness of this opinion. On the contrary, our observation leads to the conclusion that it, as well as formaldehyd glycerin solution, produces irritation of the serous membrane and promotes the formation of thick and resisting lymph deposits, assisting in blocking off the system from the infecting organisms, but in so doing effectually binding down the collapsed lung. It is greatly to be regretted that this is so, because it is the most agreeable method of treatment to use in the early stages. These three patients now have open wounds with considerable drainage therefrom, and the collapsed lungs give no signs of expansion.

The method followed to assist in the expansion of the lungs has been the blow-pipe method of blowing water from one bottle to another and in ambulatory patients the use of various mild calisthenic exercises. The water blowing procedure we regard as valuable. It has been used faithfully in all cases, including the three treated by the closed method, and it has been generally successful except in the cases in which the effect of irritating antiseptics has been the cause of the formation of thick layers of organized lymph over the compressed lung.

NECROPSY FINDINGS IN FATAL CASES

Case 1.—Empyema, right; rib resection, Oct. 29, 1918. The patient died, November 8. There was a small cavity of pus between the lung and the pericardial pleura. Small pus pockets were located in the mediastinal tissues. The pericardium contained 20 c.c. of turbid fluid. The left lung showed unresolved pneumonia. The right lung was practically solid.

Case 2.—Empyema, left; rib resection, Oct. 30, 1918. The patient died, December 5. After removal of all the thoracic viscera, an abscess was found on the left above the fourth rib containing 200 c.c. of pus. The pleural cavity below that point was drained. The pericardium was so adherent that in an attempt to separate it an opening was made directly into the right ventricle. The left lung was collapsed and firmly adherent. The right pleura contained 750 c.c. of watery fluid. A pus pocket 2 inches deep was found between the upper and the lower lobe of the left lung. The middle and lower lobes of the right sank in water. A small pocket of pus was found between the middle and the lower lobe. The left kidney was nodular in appearance. Purulent fluid exuded from the ureter.

Case 3.—Empyema, left; rib resection, Oct. 24, 1918. The patient died, November 7. The left pleura contained 400 c.c. of thick, milky, greenish yellow fluid. The right pleura was obliterated. Posterior and above the base was a pocket of purulent material. The pericardial sac contained 200 c.c. of clear, straw colored fluid. The left lung was small and sank in water. The lower lobe of the right lung posteriorly was covered with shaggy exudate. The posterior and lateral portions of the lower lobe were red and contained no air.

Case 4.—Empyema, right; rib resection, Oct. 30, 1918. The patient died, November 9. Beneath the sternum, overlying the pericardium, lay a pus pocket. The right pleural cavity contained a pocket of pus around the apex, limited by adhesions below at the level of the third rib. An adhesion extended back to the midaxillary line along the rib, and the pocket then extended downward and posteriorly to the base. There was a large abscess lying between the medial portion of the lower lobe and the pericardium. The left pleura contained 200 c.c. of bloody fluid. The pericardium contained 400 c.c. of clear fluid. The left lung was solid in the upper lobe.

Case 5.—Empyema, right; rib resection, Dec. 17, 1918. The patient died, January 1. The right lung was collapsed. Between the lung and the pericardial walls was a pocket of pus. The pelvis of the left kidney was distended and contained pus.

Case 6.—Empyema, right; rib resection, Oct. 30, 1918. The patient died, November 9. The right pleura was thickened and the cavity empty. Between the pericardium and the anterior portion of the lung lay a sealed off pocket of pus. The lower lobe of the left lung was dark, meaty red. There were scattered areas of gray hepatization. An interlobar abscess the size of a hen's egg lay between the middle and the lower lobe.

Case 7.—Empyema, Oct. 26, 1918; measles, November 7; rib resection, November 9, in the ward. The patient died, Jan. 7, 1919. The peritoneal cavity contained a large amount of greenish yellow pus. The left pleura presented dense, fibrinous adhesions. A walled off abscess formed a pocket extending from the second rib axillary line to the scapular line, with an area passing upward and backward to the vertebral column. The pericardial sac contained 25 c.c. of purulent fluid. An area of consolidation was found in both lungs. There were large amounts of thick, greenish pus in pockets between the coils of the intestine.

Case 8.—Empyema, right, Oct. 12, 1918; rib resection, October 21. The patient died, November 26. The right pleural cavity presented a pocket limited by a fibrinous coating attached to the lower border of the fourth rib. The pleural cavity below this point was obliterated. The right lung sank except at the extreme apex. The valves of the heart presented marked nodular thickening on their free borders. The aorta presented fatty degeneration about the base.

Case 9.—Empyema, right, Oct. 29, 1918; rib resection, October 30. The peritoneal cavity contained 600 c.c. of purulent fluid. The left pleural cavity contained 400 c.c. of purulent fluid. A large pocket lay above the fourth rib. The pericardium was thickened and contained 600 c.c. of purulent fluid. The stomach and intestine were covered on all surfaces with a plastic exudate.

Case 10.—The patient was admitted to the hospital, Oct. 30, 1918, for manic-depressive insanity. He had pneumonia November 4, and empyema, Dec. 9. Rib resection on the left side was performed December 12. He died December 19. The pleural sac was obliterated anteriorly. Posteriorly there was a pus pocket containing very little fluid. The pericardium was thickened and contained 200 c.c. of purulent fluid. The right kidney pelvis contained purulent urine.

Case 11.—Empyema, right, Dec. 31, 1918; thoracotomy by the closed method, Dec. 4. Dakin's solution was used until Jan. 1, 1919. Rib resection was performed January 8. The patient died January 29. The left pleural cavity contained 900 c.c. of fluid. The pericardial sac contained 20 c.c. of fluid. The right lung was densely adherent and sank in water. There was some pus in the peritoneal cavity.

Case 12.—Empyema, left, Oct. 25, 1918; measles, November 12; rib resection, October 28. The patient died, November 24. The left pleural cavity contained a small amount of pus. The right pleural was free of fluid. The lung was adherent to the pericardial pleura. The pericardial sac contained 480 c.c. of pus. Throughout all lobes of the lungs, shotlike nodules were palpated.

Case 13.—Empyema, left, Nov. 1, 1918; purulent pericarditis, November 13. The patient died, December 6. The pericardial sac was large and contained 1,000 c.c. of pus. The left pleural cavity was obliterated. At the posterior and lower border of the right lung there was an abscess cavity measuring 13 by 7.5 by 4.5 cm.

Case 14.—Empyema, left, Oct. 27, 1918; rib resection, October 28. The patient died, November 14. The right pleural sac contained 1,100 c.c. of serous fluid. The left pleura was thickened and contained no fluid. The lower lobe of the left lung sank in water. The right lung was covered on all surfaces by a fibrous exudate. Pockets of pus were found between the lobes.

Case 15.—Empyema, left, Oct. 27, 1918; measles, November 17; rib resection, October 28. The patient died, November 18. The right pleura contained 600 c.c. of purulent fluid. The pericardial sac was obliterated. The lower lobe of the left lung sank in water. The middle and lower lobes of the right lung contained firm nodules.

Case 16.—Empyema, right, Nov. 8, 1918; rib resection, November 23. The patient died, April 15, 1919. There was an empyemic cavity, 3 by 4 inches, well drained. Miliary tubercles were distributed throughout both lungs.

PATIENTS RECEIVED BY TRANSFER

In addition to the seventy-one cases originating in this camp since July 1, 1918, this service has received thirty patients by transfer from overseas and from other camps. Among these patients there were three who had been sick more than a year. One had pneumonia and empyema at Camp McArthur in the spring of 1917. He recovered and went overseas, and the sinus in the chest wall reopened eight months later. He had passed through many hospitals and had been operated on several times. When admitted here he had a large cavity with complete collapse of the lung. The ribs previously removed had reformed, presenting many fantastic forms. He was operated on here and did very well for a time, but died following a second operation which was not considered a severe one. Necropsy revealed advanced tuberculosis in the opposite lung. One of the other patients had taken sick on a transport in March, 1918, where he had remained until May, when he was landed in New York. He had passed through five operations, and still presents a discharging sinus from a small pleural cavity. The third one was a patient of Camp Dodge base hospital and General Hospital No. 26 for a year, and when admitted here had a discharging sinus from a large pleural cavity, which healed rapidly after resection of four ribs. Many of the overseas cases resulted from gunshot wounds.

Of the patients received by transfer, one died, fourteen recovered and were returned to duty, and fifteen are still in the hospital in good general condition, ambulatory and apparently convalescent.

It will be noted that none of our patients died of uncomplicated empyema, but rather from an intense general infection in which the pleural inflammation constituted but one factor in the case. It will also be noted that it is comparatively easy to render the pleural cavity sterile, but that such accomplishment does not mean the cure of the patient, and that no case should be pronounced cured until the expansion of the lung has produced contact with the thoracic wall and obliterated the infected space.

CONCLUSIONS

1. Empyema, as it has occurred in this camp, is but one element in an intense pneumococcic infection to which in many cases the streptococcus has been added without apparently influencing the progress of the disease.

2. The presence of fluid in the pleura is at first protective to the diseased lung, and it should not be

removed at an early period unless it is replaced, in part, by some other fluid.

3. If the patients survive the pneumonic process and the fluid becomes purulent, it should be drained through a large tube introduced after a rib resection under a local anesthetic, and under no circumstances should this procedure be adopted before the twelfth day of the disease, and so early as that only under exceptional circumstances.

4. Drainage having been established at the most dependent point in the cavity, irrigations with, or instillations of, irritating chemical solutions should be abstained from. If the drainage is adequate they will not be required. If not adequate, flushing with physiologic sodium chlorid solution will be all that will be required, and as soon as practicable, adequate drainage should be provided.

5. Attention is invited to the fact that this summary brings us to the adoption of the prewar theory of the surgical treatment of empyema, dismisses the theory so often advanced that a soldier requires different treatment than a civilian, and that the lung disease differs in any sense from the corresponding infection in civil life, except in the degree of severity caused by overcrowding, and relegates to the boneyard all of the many fancy treatments of empyema evolved by the faddists who have been privileged to observe a series of cases for a limited period of time. It has been my fortune to observe the final period of one epidemic of empyema and nearly the whole period of a second epidemic at this camp. I entered on the direction of the surgical treatment to be followed in the second epidemic with an open mind, without prejudice, and filled with a hope that formaldehyd glycerin solution instillation during the early stages of this disease would be beneficial. The use of Dakin's solution had been tested here in the first epidemic, and universally condemned by every surgeon who had handled it, and yet I insisted on its use in five cases by the open method and in three by the closed method with the results as stated above. I am now firmly of the opinion that the long established principles of surgery as evolved by many years of experience in civil life and enunciated in practically every textbook on surgery as the proper treatment of empyema has not been shaken from its foundation by any of the fads and fancies evolved during the war period.

Statistical Studies of the Influenza Epidemic Being Made by the U. S. Public Health Service.—Statistical studies are now being undertaken by the Public Health Service relative to the influenza epidemic. These studies comprise five main divisions: (1) special surveys to determine the incidence rate, type, duration and fatality of influenza in representative areas in different sections of the country in relation to color, age, sex, household congestion and time of occurrence; (2) detailed analyses of morbidity records available through state health departments to show chiefly the chronology, sex and age distribution of cases as reported; (3) preliminary analyses of records of epidemic mortality in a few states with reference to the mortality in various civil subdivisions by color, sex and age groups in successive periods of the epidemic; (4) a special inquiry into the nature and scope of preventive and relief measures adopted in larger cities to combat the epidemic. (5) In addition, certain compilations and analyses are being made from available published data, including current mortality statistics from certain foreign countries, and mortality from influenza and pneumonia in previous years in the United States. A special statistical office has been established under the direction of Surg. W. H. Frost and Statistician Edgar Sydenstricker, with Dr. Raymond Pearl of the Johns Hopkins University School of Hygiene and Public Health as consultant.

UNILATERAL ANESTHESIA OF THE CORNEA AND CONJUNCTIVA

A DIAGNOSTIC SIGN OF COMA DUE TO HEMIPLEGIA

E. D. FRIEDMAN, M.D.
Instructor in Medicine, University and Bellevue Hospital Medical College; Adjunct Assistant Attending Physician, Third Medical Division, Bellevue Hospital
NEW YORK

A physician may at any time be confronted with the necessity of determining the cause of coma; it is often difficult to say whether one is dealing with a postepileptic state, uremia, some toxic condition, or hysteria. We have found a sign which has been of great value in establishing the diagnosis of coma due to hemiplegia. It is known that in profound coma all reflexes are abolished; but in cases of moderate stupor or confused states this sign has helped to establish the diagnosis. The sign is a unilateral anesthesia of the cornea on the side of the hemiplegia, that is, the side opposite the lesion.

It has long been known and recently emphasized that the unilateral diminution, or absence of the abdominal wall reflexes, is an important sign of hemiplegia. We have found that in some instances, particularly in women with flabby abdominal musculature, it is difficult to elicit this sign. In such cases, and in all others for that matter, the unilateral absence of the corneal reflex is very helpful.

One must recall that the corneal reflex is a consensual reflex. The introduction of a foreign body into one eye produces a winking reflex in both eyes. This reflex is essentially protective, and apparently belongs to those mediated through the brain. It can be elicited by carefully passing a small blunt object along the conjunctiva to the corneal margin. One must guard against reaching the pupillary area because of the possibility of eliciting a visual reflex, which is present even in moderately stuporous cases. We have found this reflex absent in practically all hemiplegias with, and without, coma. We have not yet had occasion to study this sign in cases of crossed hemiplegia.

ABOLITION OF THE REFLEX

In looking through the literature we found only a single reference to this subject, one by Milian.[1] He attributed the loss of the reflex to the lesion of the facial nerve, that is, the motor arc, and he thought that in crossed lesions the abolition should occur on the same side as the facial paralysis. From our observations we must take issue with him, because if the absence of the reflex were due to interference with the motor arc, the consensual reflex should still be present on the other side. The sign should also disappear with the return of innervation of the facial nerve, which occurs in many cases. We have found, in our cases, no evidence of a consensual reflex, and, in some cases, we have been able to elicit the reflex on the paralyzed side by testing the cornea of the healthy side. This proved that the abolition of the reflex was not due to interference with the motor arc but due to the anesthesia of the cornea and conjunctiva.

The anesthesia of the cornea may be due to the presence of sensory fibers in the motor pathways, which are injured by the lesion causing hemiplegia, or, what seems more likely, is due to Monakow's diaschisis, with radiation of the insult to the sensory tracts. In cases with pure lesion of the motor tracts this sign tends to disappear after a few days. In lesions close to the thalamus, there is a tendency for the hemianesthesia to persist.[1]

---

[1] Milian: Progrès méd. 25:229 (May 1) 1909.

Among our observations there have been many cases in which this has been the only sign of hemiplegia. In one case of what looked like a spasm of the cerebral vessels with transient right sided hemiparesis and doubtful Babinski, there was an absence of the corneal reflex on that side, thus proving the delicacy of this test for hemiplegia.

This sign should be especially valuable to the ambulance surgeon. It would help him in the differentiation of comotose states, so that he would not be too ready with the diagnosis of alcoholism. It is also very important from the standpoint of therapy. Given the diagnosis of hemiplegia, the treatment will necessarily be purely expectant, quite the opposite of the active treatment necessary for uremia.

There is only one condition that we can think of which would present difficulty in diagnosis. That condition is fracture of the base of the skull, involving the posterior fossa with injury to the trigeminus. In such cases, however, evidence of injury to the other nerves of the posterior fossa, the roentgenographic findings, the possible presence of blood in the spinal fluid, and the subsequent clinical course would help in the differential diagnosis. It is our hope that the test will be tried, and its value established through more extensive observation than our own.

INTRAVENOUS INJECTIONS OF FOREIGN PROTEIN IN INFLUENZAL PNEUMONIA

CLIFFORD W. WELLS, M.D. (Chicago)
Captain, M. C., U. S. Army
CAMP TRAVIS, TEXAS

This report deals with the results from the intravenous injection of a foreign protein in eleven cases of influenzal pneumonia. Nine of the patients were critically ill and presented a grave prognosis. The protein used consisted of typhoid bacilli, macerated and exposed to the soluble action of alcohol for twelve hours, washed free of alcohol and suspended in physiologic sodium chlorid solution, the concentration being the equivalent of approximately three million bacilli per cubic centimeter. The dose employed was sufficient to produce a definite, so-called protein reaction, as a rule 1 c.c. Leukocyte counts were made previous to the injections, and from four to twelve hours following the reaction. In several cases blood chemistry determinations were made before and after the injections.

From thirty to forty-five minutes after the injections the patients experienced a typical protein reaction, characterized by a severe chill and moderate cyanosis, lasting from fifteen to twenty minutes and followed by a period of profuse sweating and marked elevation of temperature. Shortly following the period of sweating the patients invariably felt and appeared much improved. In several cases, notably Cases 2, 6 and 11, following the marked elevation of temperature, there occurred a rapid crisis with no subsequent rise in temperature, the patient going on to complete recovery.

Case 1.—Jan. 10, 1919, the patient developed influenza and Jan. 13 pneumonia involving both lower lobes was diagnosed. Bacteriologic examination of the sputum showed Type IV pneumococcus as the predominating organism. The patient received 1 c.c. of protein at 3 p. m., January 13. Blood pressure before the injection was: systolic, 124; diastolic, 68; one hour following the reaction: systolic, 132; diastolic, 68. The leukocyte count before the injection was 5,500, with 65 per cent. polymorphonuclear elements; six hours after the injection the count was 7,040. Blood chemistry of blood obtained four hours after the injection showed: urea nitrogen, 18.2 mg. per hundred cubic centimeters, urea, 38.2 mg. per hundred cubic centimeters. Carbon dioxid combining power of the blood plasma was 57 per cent. January 14, the leukocytes were 7,920. January 15, a second injection of 1 c.c. of protein was given. The leukocytes before the injection were 4,840, and seven hours after the reaction 6,380. This patient did not respond to the protein injections sufficiently to warrant its further use. Death occurred, January 19. In this case the slight increase in the number of leukocytes can probably be attributed to the protein injected; but the increase was not at all commensurate with the severity of the reaction that occurred following the injection. The slight increase is probably due to the marked inhibition of the leukocytic-forming organs because of the toxins resulting from the infection.

LEUKOCYTIC REACTION FOLLOWING THE INTRAVENOUS PROTEIN INJECTIONS IN ELEVEN CASES OF PNEUMONIA

Case	Day of Injection	Leukocytes Before Injection		Leukocytes After Injection		Hours after Injection	End-Results	Type of Case
		Total Number	Polymorphonuclears, per Cent.	Total Number	Polymorphonuclears, per Cent.			
1	1/13/19	5,500	65	7,040	..	6	Death	Critical
	1/15/19	4,840	..	6,380	..	7		
2	1/13/19	3,740	..	10,560	..	6	Recovery	Serious
3	1/23/19	5,720	82	15,840	95	4	Empyema and death	Critical
	1/24/19	.....	..	13,640	86	4		
	1/25/19	.....	..	11,660	90	6		
	1/30/19	9,900	88	17,600	72	6		
4	1/16/19	6,160	..	7,920	..	4	Death	Critical
	1/17/19	2,420	..	7,700	..	4		
5	1/20/19	8,360	..	14,300	..	12	Recovery	Serious
6	1/28/19	4,840	65	5,500	..	12	Death from empyema	Critical
	1/30/19	5,720						
	2/ 1/19	9,900	70	17,820	68	6		
	2/ 2/19	14,740	79	16,720	81	6		
7	1/19/19	5,940	71	4,840	..	2½	Recovery	Serious
8	2/12/19	3,960	78	3,740	72	12	Recovery	Mild
9	1/26/19	.....	..	5,500	68	2	Recovery	Mild
10	3/31/19	3,960	68	7,260	70	9	Recovery	Serious
	4/ 1/19	.....	..	6,820	78	3		
	4/ 2/19	7,040	77	4,840	91	4		
11	1/22/19	6,380	83	16,720	..	10	Recovery	Serious

Case 2.—Jan. 7, 1919, the patient developed influenza, and January 13, bronchopneumonia involving both lower lobes was diagnosed. January 13, 1.5 c.c. of protein were injected intravenously. Forty-five minutes later there occurred a severe chill lasting twenty minutes, followed by profuse sweating. The findings in the blood before injection were:

Creatinin, 2.10 mg.; urea nitrogen, 17.2 mg.; urea, 36.8 mg.; uric acid, 6.0 mg. per 100 c.c. Carbondioxid combining power of the blood plasma 48 per cent.; leukocytes, 3,740; blood pressure, 112-64.

The blood findings six hours after the injection were:

Creatinin, 2.00 mg.; urea nitrogen, 16.3 mg.; urea, 34.88 mg.; uric acid, 5.00 mg. per 100 c.c.; leukocytes 10,560; blood pressure, 134-80.

In this case the temperature dropped to normal ten hours after the injection and the patient went on to a complete recovery.

Case 3.—Jan. 18, 1919, the patient developed influenza and January 22, pneumonia involving both lower lobes was diagnosed. January 23, 0.75 c.c. of protein was given intravenously. Leukocytes before the injection were 5,720, with 78 per cent. polymorphonuclear elements; four hours after the injection the count was 15,840, with 95 per cent. polymorphonuclear elements.

---

[1] It is, of course, understood that the anesthesia of the cornea and conjunctiva is only part of a cortical hemianesthesia, and the value of the sign depends on its absolute objectivity.

Blood chemistry before this injection showed:

Creatinin, 1.01 mg.; urea nitrogen, 20.7 mg.; urea, 44.29; uric acid, 3.65 mg. per 100 c.c. Carbon dioxid combining power of the blood plasma was 51 per cent.

Second and third injections of the protein were given, January 24 and January 25, maintaining the leukocyte counts around 12,000 and the percentage of polymorphonuclear elements between 85 and 90. January 30, the leukocytes had dropped to 9,900. A fourth injection was given on this day, which increased the count to 17,600, with 72 per cent. of polymorphonuclear elements. January 31, a serofibrinous pleurisy was diagnosed. February 5, operation was performed for empyema; death ensued, February 8. After January 31, the leukocyte counts remained over 20,000 and no further injections of protein were indicated. Chart 1 shows the temperature reactions following the first three protein injections.

Case 11.—Jan. 16, 1919, the patient developed influenza and January 21, bronchopneumonia involving the left lower lobe was diagnosed. January 22, 1 c.c. of protein was given intravenously, which was followed in forty-five minutes by a severe chill. The leukocytes before the injection were 6,380, ten hours after the injection the count was 16,720. Following the reaction the temperature dropped to normal and remained so until the patient was discharged from the hospital.

Eleven cases were available for this study. With two exceptions cases were selected that were critical and in which leukocyte counts were definitely of the leukopenic type, the aim being, if possible, to provoke a leukocytosis. Because of the few cases, the results, on paper, are not as convincing as they might otherwise be. Of the eleven cases, eight showed, following the injections, an increase in the total number of leukocytes, only five however an increase worth noting. In those cases showing a marked increase there was noted an increase in the proportion of the polymorphonuclear leukocytes. The three cases in which only a slight increase in the number of leukocytes occurred resulted in recovery. The two mild cases included in this series ended with recovery. Of the nine cases remaining, four resulted fatally; two, however, from empyema, after the development of which protein injections were not made, as a high leukocyte count had developed as a result of the complication.

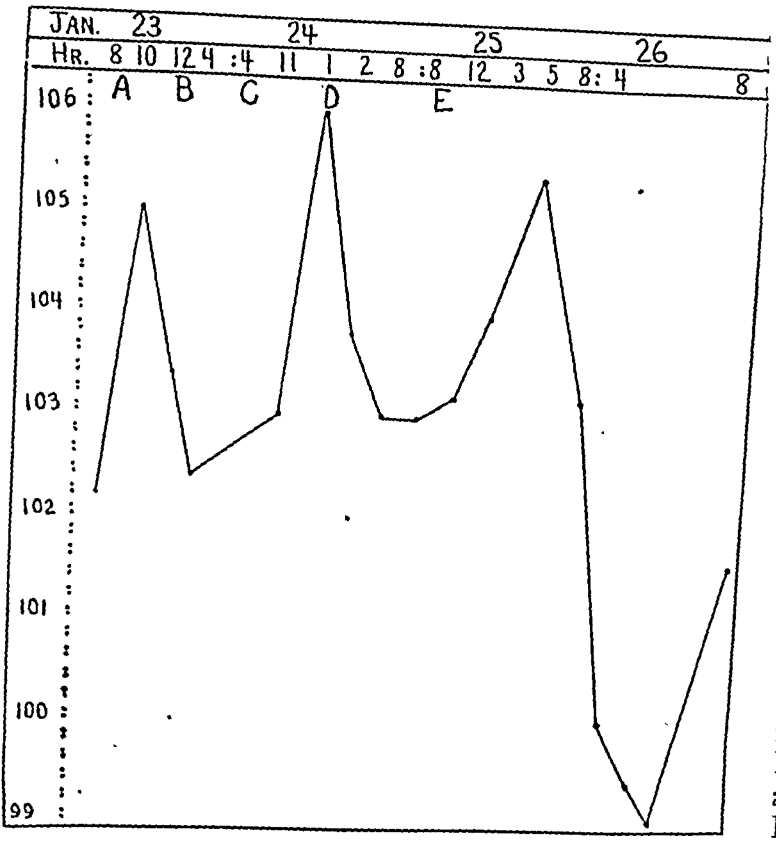

Chart 1 (Case 3).—Temperature reaction following three injections of protein: *A*, leukocyte count, 5,720; intravenous injection of 0.75 c.c. of foreign protein; *B*, leukocyte count, 15,840; *C*, injection of 1 c.c. of foreign protein; *D*, leukocyte count, 13,640; *E*, leukocyte count, 11,600; injection of 1 c.c. of foreign protein.

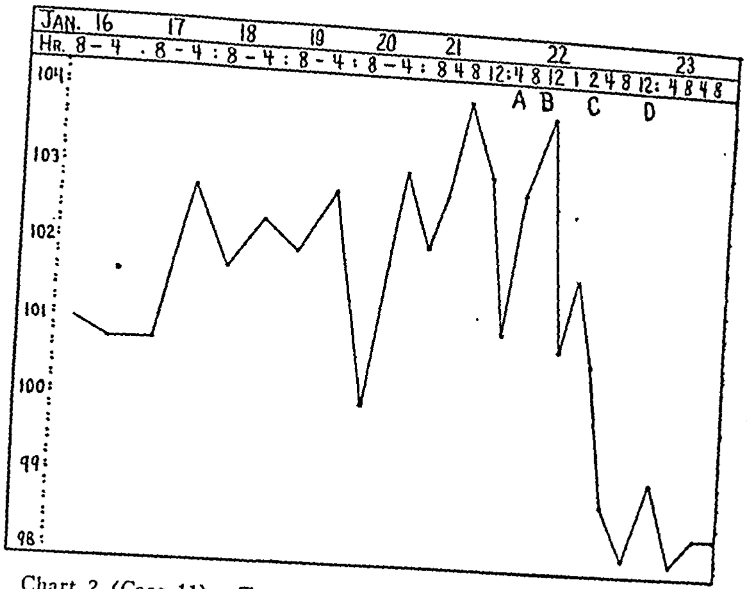

Chart 2 (Case 11).—Temperature reaction following protein injection: *A*, leukocyte count, 6,380; injection of 1 c.c. of foreign protein; *B*, marked chill, 11 a. m.; *C*, leukocyte count, 16,720; *D*, temperature normal.

So far as could be determined, the intravenous injection of typhoid protein has no deleterious effect, as regards an increased retention of the products of katabolism. This finding is in accord with the results obtained with the use of other protein extracts by McQuarrie and Whipple.[1] Mackenzie has mentioned the occurrence of diminished blood pressure following the injection intravenously of certain proteins. In this series two cases showed an increase in blood pressure, while the others investigated in respect to this point were normal.

Metschnikoff and his school have emphasized the importance of the polymorphonuclear leukocytes in natural and acquired immunity against bacterial infections. The medical profession has long attached considerable prognostic importance to a high leukocyte count, particularly in pneumonia. Recognizing the occurrence of a low leukocyte count in the blood of a vast majority of the influenzal pneumonias, it seemed logical, from the above point of view, to attempt to stimulate an increase of these cells in this condition. The occurrence of a leukocytosis following the injection of certain proteins has been demonstrated by many investigators. The results obtained by Miller and Lusk, and others, in their intravenous use in arthritis; and their use in pneumonia by the writer and the late Dr. Mathers (results not published), led us to apply them in the condition which is the subject of this paper. Those who have had experience with pneumonia following influenza appreciate the grave condition present in a certain percentage of these cases, in which the use of all previously known measures of treatment have been futile. This fact warranted the attempt made in this study.

Recently, Roberts and Cary[2] reported the use of intravenous injections of heat-killed pneumococcus, streptococcus, staphylococcus and influenza bacilli in cases of influenza, in an attempt to abort pneumonia. These writers state that no untoward results followed such injections, and concluded that in their opinion protein injections have a definite therapeutic value in the disease under consideration. It is our opinion, based on the above-mentioned eleven cases and some experience with intravenous protein therapy in primary pneumonias, that the intravenous injection of foreign protein is efficacious in selected cases when made by one thoroughly conversant with all the possibilities of the therapy. Such injections, however, should not be employed as a routine by the general practitioner.

NEWER METHODS FOR RADIUM TREATMENT OF PROSTATIC AND VESICAL CANCER

FRANK HINMAN, M.D.
SAN FRANCISCO

Since the early publications of Pasteau[1] and co-workers highly commending the use of radium for prostatic cancer, many eminent urologists—Barringer and Keyes, Marion, Young and others—have reported encouraging and hopeful results in the treatment with radium of both prostatic and vesical cancer.

The methods of use for cancer here, and of other parts of the body, have been practiced sufficiently long to establish certain principles. In the first place, it is important to control the dose of radiation by proper screening, accurate placement and limitation of exposure, so that radium burns may not be produced. In the second place, close approximation of the radium element to the area for radiation gives far better results than radiation at a distance, even when enormous doses are thus used.

METHODS OF TREATMENT

Various methods have been adopted by the different advocates of radium. The simplest is the ordinary rubber catheter as used by Pasteau, and now in common use, by which the radium may be placed in the rectum, the urethra or the bladder. The radium capsule in the catheter end may be directed fairly well by a stylet, or, with the bladder empty, the area to be treated may be presupposed to come into contact with the catheter end containing the radium, on its simple insertion. As suggested by Barringer,[2] tumors on the anterior wall or on either lateral bladder wall of the bladder may be more directly placed in contact with the radium by having the patient lie on his stomach or on the respective side involved, so that the radium capsule will come by gravity to lie over the tumor area. Barringer places the radium capsule in the bladder through the sheath of the cystoscope, which is then withdrawn, and the capsule is allowed to remain from six to ten hours. It is removed by means of a thread left hanging through the urethra.

For cancer of the prostate, Barringer plunges long needles through the perineum directly into the prostate, leaving them about twelve hours, the patient being under local anesthesia. Marion[3] uses a large hydrocele trocar in a similar manner, plunging it through the perineum, its point being guided by a finger in the rectum. The needle obturator is then removed and the radium capsule, with silver wire attached, is pushed through the sheath into the prostate, and the trocar is withdrawn. The capsule can be pulled out at the desired time by means of the wire. Burrows[4] has devised a special trocar with a slot for these particular perineal radium treatments. Young[5] has utilized the principles of his cystoscopic rongeur, and devised several instruments by means of which the radium tubes may, under direct cystoscopic vision, be accurately placed on bladder tumors, and then held in position by means of a mechanical arm attached to the cystoscopic table. For treatments per rectum he uses a special instrument shaped much like a sound, the end of which, containing the radium, is placed with the finger at the point desired and, with the patient lying on one side, held in place by a mechanical arm attached to the table. Young's methods for the bladder, by their added accuracy, diminish the likelihood of radium burns and enable the safe use of more frequent applications.

Rectal tube

Fig. 1.—Apparatus for treating carcinomatous prostate by rectum.

USE OF INSTRUMENTS

In the treatment of eight cancerous prostates, I have had rectal burns in three patients. The radium has been inserted in a catheter and held in place by means of a heavy wire stylet, in a manner similar to that used by Young. Few patients can remain quietly in one position for the required period. In order to protect the walls of the rectum not required to be exposed to the rays, and to relieve the patient of the effort of remaining for hours in one position, the instrument shown in Figure 1 has been satisfactorily used during the last year in the treatment of four patients. The radium is first placed in the radium pockets. The amount of radium and the pocket used depend on the point of radiation desired—whether prostate or left or right vesical area—and on the type of case and previous treatments. The pouch is then inserted while collapsed, and the radium pocket or pockets are accurately placed at the desired position by a finger in the rectum. Collargol, or some solution impermeable to the rays, is then injected into the pouch, the amount of distention desired being known by previous measurement, and the injection tube is clamped. The distended bag pushes the radium pocket snugly against prostate or vesical wall and holds it in place irrespective of the position of the patient. The rectal tube perforating the bag allows the passage of intestinal gas, so that the bag may be retained for hours without discomfort. The solution in the bag furnishes a filter which thoroughly protects all portions of the rectum except the small area directly in contact with the radium pocket.

For intravesical treatments the catheter method has likewise proved unsatisfactory in my experience. The method as illustrated in Figure 2 has proved simple and efficient in the treatment of three cases of bladder cancer during the last year. The instruments consist of a brass capsule, with a screw cap, for holding the radium. At the other end is a square shoulder into which a wire 25 inches long is firmly fastened (*b*). The wire is threaded into a holder (*a*), curved near the end, at which is a square socket into which the square shoulder of the radium capsule firmly fits. At the other end is a screw which, by compressing the wire, holds the capsule firmly in the socket of the holder and forms a solid radium sound. This sound is first inserted into the bladder (*c*), and for radiation of the trigone or areas near the vesical neck can be accurately placed with the finger in the rectum as a guide, and held in position by a mechanical arm. For tumors on the apex or other portions of the bladder, however, more accurate placement is desired. The screw of *a* is loosened and the wire pushed through the sound so as to displace the radium holder from its socket. The sound can then be withdrawn through the urethra, leaving the holder in the bladder with the wire guide through the urethra. A No. 16 F Brown-Buerger single catheterizing cystoscope is then threaded on the wire into the bladder and, by means of its lever, the radium holder can be guided, as if it were an ureteral catheter, to any portion of the bladder desired (*d*), and held in this position by fixing the cystoscope to the table with a mechanical arm. The flexibility of the wire allows the holder to take a parallel position to any portion of bladder wall or tumor area.

ANGIONEUROTIC EDEMA

REPORT OF CASE

EDWARD T. EDGERLY, M.D. (Ottumwa, Iowa)
Major, M. C., U. S. Army
CAMP DODGE, DES MOINES, IOWA

AND

FRANK B. LUSK, M.D. (Chicago)
Captain, M. C., U. S. Army
FRANCE

The case reported, while in the main one of angioneurotic edema, differs from the type commonly seen in that it embodies in its manifestations almost all the features of this disease. Its decided hereditary tendency, its appearance early in life, its persistent and frequent attacks, with pronounced local and general manifestations and a clinical course at times suggestive of an acute infection, stamp it as unusual. The possibility of confusing it with the expression of some sudden severe systemic derangement, the protean manifestation of some vascular disturbance such as acroparesthesia, or classifying it as the familial type of edema described by Edgeworth or even as Milroy's disease is not unlikely.

REPORT OF CASE

History.—L., a white man, aged 24, born in Missouri, where he resided until his induction into military service, entered the base hospital at Camp Dodge, July 24, 1918, with the provisional diagnosis of "edema, origin undetermined." The attacks, he stated, began July 22, 1918, two days before admission, with a feeling of fulness and tension of both palms and soles accompanied by slight tingling and numbness. The following morning he awakened to find both hands, forearms, feet, legs, and thighs one-half again their natural size. The genitalia also were very much swollen. On the afternoon of the same day both upper and lower eyelids, cheeks, and, to a lesser extent, his tongue, became involved so that sight was almost impossible and speech and mastication difficult. The parts previously described continued swollen. The condition gave rise to but little discomfort, although the inconvenience of being unable to put on his clothing and shoes and the inability to use his hands incapacited him for his routine duties.

Physical Examination.—On the third day, that of admission to the hospital, the swelling subsided to some extent. The patient was 5 feet and 10 inches in height, weighed 175 pounds, and though not robust was not of an unhealthy appearance. All organs such as the eyes, ears, heart, lungs, and abdominal viscera were free from any palpable abnormalities. The eyelids exhibited an appearance such as one might expect in an edema the result of an acute diffuse nephritis. The cheeks and skin of the neck were puffy, but did not pit on pressure, while the tongue was grossly thickened but otherwise normal. The skin of the chest and abdomen, while of a fine texture, appeared thickened. It was somewhat blanched, dry and tense, with slight pitting on pressure. The skin of the upper and lower extremities presented much the same general phenomena, but the feet and hands were shiny, having a tense, slick appearance. They felt cold and clammy, and were a dark, dull, purplish red, with here and there a bit of white mottling. Moderately firm pressure resulted in some pitting, lasting from one to three minutes, while the subsequent blanching disappeared immediately, leaving a decidedly erythematous area. There was no dermographia or itching.

This attack lasted in all six days, disappearing gradually. Subsequent to this he had five attacks of from one to three days' duration during the six weeks of observation in the hospital. All were less severe, and each differed in some respect from the one described. In some the onset and duration covered only a few hours, while in others merely the hands were involved. These sometimes were very white and warm, at other times red and cold with numbness, tingling, and formication.

On the day of his admission, his temperature was 101.6 F., pulse 78, respiration 20. The red blood count was 4,780,000, hemoglobin 100 per cent. (Sahli), and the white blood count 20,000 with no noteworthy changes in the differential count. The blood pressure was 115 systolic and 85 diastolic. The following day the temperature, pulse and respiration were normal, and the white blood count fell to 9,000. In the second and fourth attacks there was again some rise in temperature and a moderate increase in the number of leukocystes. The urine, stool and blood Wassermann test were repeatedly negative, as were roentgenographic examinations of the gastro-intestinal tract, the sella turcica and the bones of the extremities. Neurologic examination was negative.

Past History.—The patient had been free from previous diseases, including nervous and venereal diseases, nor could there be elicited any history of dietetic or gastro-intestinal disorders. He was told by his parents that even in early childhood he had had similar attacks, occurring as frequently as two or three times a year. His own recollection dates back to the age of 14 years, at which time an attack not unlike the present occurred; but at that time he had in addition a markedly swollen tongue which seemed to fill his mouth completely, severe dyspnea, so that he feared choking to death, and abdominal cramps, without, however, any diarrhea. This attack fluctuated in severity from day to day, lasting in all fifteen days and undergoing a gradual decrudescence. He had had but one other such attack, which occurred when he was 17. Minor attacks, however, as the one described above, have been frequent, occurring as often as once a week. The onset of these covered from two to twenty-four hours, and lasted, in all, from twenty-four hours to three days.

Family History.—The grandparents on both sides died in old age. The mother and father are living and well. One uncle, the father's brother, has three children; the second, a boy of 24, has had several attacks of the same disorder. In the immediate family there are seven children.

The oldest, a sister of 36, occasionally has manifestations in which only the feet and hands are involved. A brother, aged 31, has attacks similar to those of this patient, with frequent involvement of the chest, marked dyspnea, "choking spells," and abdominal cramps. Another brother, aged 29, is living and well. A sister, aged 26, having at present pulmonary tuberculosis, is affected with the same disease to only a moderate extent. Two other brothers, aged 18 and 10, have always been in good health.

Triumph of Medicine in the War.—How important is the part that medicine plays in national welfare has been strikingly shown in the recent war. Whatever may be the verdict of history on the diplomatic, political, naval, military and economic phases of the war, there will be no hesitation about the brilliant triumphs of curative and preventive medicine. These triumphs have been partly the outcome of the researches and investigations of contemporary workers, not only in the science and art of medicine but also in the allied sciences of chemistry and physics and biology; but the victory was eventually ensured by the thousands of trained workers who knew how to make full use of all the resources which these sciences had placed at their disposal. Medical men of different nationalities, sometimes of different races, reared under different educational and social systems, were able to cooperate in the common endeavor, because they had all alike inherited the same traditions of rational medicine.—Tweedy, *Brit. M. J.* 2:597 (May 17), 1919.

THE OPHTHALMOLOGIST AND THE PHYSICIAN *

CHARLES P. EMERSON, M.D.
Dean and Professor of Medicine, Indiana University School of Medicine
INDIANAPOLIS

Each decade presents to the medical man a new problem; that is, the advancing edge of his science is ever shifting. Progress at one point permits of progress at other, formerly quieter zones. Twenty years ago a large group of medical patients were not well treated. "Neurasthenics" they were called, or, if they seemed likely to resent that name, they were assured that they were "only nervous," that they "had no organic trouble." The average general practitioner did not know how to help them, and so by his unsympathetic attitude he drove them into the churches and offices of various sects antagonistic to medicine.

The improved methods of diagnosis and the great recent advances in our knowledge of the functional neuroses have, however, proved to us that very many of these patients can be helped, some very easily. Many complain of easy fatigability alone, which may be due to various common diseases in their earlier stages before any characteristic symptoms have appeared, usually diseases of the central nervous system or of the cardiovascular-renal organs. Several other groups may be separated; but only one interests us now, a large group of patients with no real disease but who are handicapped by some mental or physical defect, often permanent in character, which leads to symptoms which the patient accepts as a part of his life and which may in time, because of the fatigue and suffering produced, lead to nervous or even to mental breakdown. The conditions which this group of patients presents are very complex. Several factors work conjointly in the production of symptoms, but one is so important that I invite you to discuss it now with me. I refer to eyestrain in persons whose nervous makeup is such that this strain alone can lead to results of greater or less importance, or at least can modify a syndrome produced by some other injuring factor. I would avoid emphasizing eyestrain as the sole cause of any symptom. In these cases it usually is not. The real cause is more likely to be in the neuropathic disposition of the patient himself. These patients all deserve careful and sympathetic study, since many are greatly relieved by the proper correction of errors of refraction. The point, however, which now I would make is that these patients cannot be helped by the ophthalmologist alone any more than by the internist alone. He requires their combined efforts. I invite you today to such consultation with the subject of eyestrain as our patient. I would not for one moment claim that the subject is new. Nearly every symptom and disease from heterodoxy in religion to ingrowing toenail has been ascribed to eyestrain. It would not be wise before this audience to increase this list without good reason, but an intensive study of certain indirect results may be timely, for only by such studies can we improve our methods of diagnosis and increase our efficiency in treatment.

amount of radium and the pocket used depend on the point of radiation desired—whether prostate or left or right vesical area—and on the type of case and previous treatments. The pouch is then inserted while collapsed, and the radium pocket or pockets are accurately placed at the desired position by a finger in the rectum. Collargol, or some solution impermeable to the rays, is then injected into the pouch, the amount of distention desired being known by previous measurement, and the injection tube is clamped. The distended bag pushes the radium pocket snugly against prostate or vesical wall and holds it in place irrespective of the position of the patient. The rectal tube perforating the bag allows the passage of intestinal gas, so that the bag may be retained for hours without discomfort. The solution in the bag furnishes a filter which thoroughly protects all portions of the rectum except the small area directly in contact with the radium pocket.

For intravesical treatments the catheter method has likewise proved unsatisfactory in my experience. The method as illustrated in Figure 2 has proved simple and efficient in the treatment of three cases of bladder cancer during the last year. The instruments consist of a brass capsule, with a screw cap, for holding the radium. At the other end is a square shoulder into which a wire 25 inches long is firmly fastened (*b*). The wire is threaded into a holder (*a*), curved near the end, at which is a square socket into which the square shoulder of the radium capsule firmly fits. At the other end is a screw which, by compressing the wire, holds the capsule firmly in the socket of the holder and forms a solid radium sound. This sound is first inserted into the bladder (*c*), and for radiation of the trigone or areas near the vesical neck can be accurately placed with the finger in the rectum as a guide, and held in position by a mechanical arm. For tumors on the apex or other portions of the bladder, however, more accurate placement is desired. The screw of *a* is loosened and the wire pushed through the sound so as to displace the radium holder from its socket. The sound can then be withdrawn through the urethra, leaving the holder in the bladder with the wire guide through the urethra. A No. 16 F Brown-Buerger single catheterizing cystoscope is then threaded on the wire into the bladder and, by means of its lever, the radium holder can be guided, as if it were an ureteral catheter, to any portion of the bladder desired (*d*), and held in this position by fixing the cystoscope to the table with a mechanical arm. The flexibility of the wire allows the holder to take a parallel position to any portion of bladder wall or tumor area.

ANGIONEUROTIC EDEMA

REPORT OF CASE

EDWARD T. EDGERLY, M.D. (Ottumwa, Iowa)
Major, M. C., U. S. Army
CAMP DODGE, DES MOINES, IOWA
AND
FRANK B. LUSK, M.D. (Chicago)
Captain, M. C., U. S. Army
FRANCE

The case reported, while in the main one of angioneurotic edema, differs from the type commonly seen in that it embodies in its manifestations almost all the features of this disease. Its decided hereditary tendency, its appearance early in life, its persistent and frequent attacks, with pronounced local and general manifestations and a clinical course at times suggestive of an acute infection, stamp it as unusual. The possibility of confusing it with the expression of some sudden severe systemic derangement, the protean manifestation of some vascular disturbance such as acroparesthesia, or classifying it as the familial type of edema described by Edgeworth or even as Milroy's disease is not unlikely.

REPORT OF CASE

History.—L., a white man, aged 24, born in Missouri, where he resided until his induction into military service, entered the base hospital at Camp Dodge, July 24, 1918, with the provisional diagnosis of "edema, origin undetermined." The attacks, he stated, began July 22, 1918, two days before admission, with a feeling of fulness and tension of both palms and soles accompanied by slight tingling and numbness. The following morning he awakened to find both hands, forearms, feet, legs, and thighs one-half again their natural size. The genitalia also were very much swollen. On the afternoon of the same day both upper and lower eyelids, cheeks, and, to a lesser extent, his tongue, became involved so that sight was almost impossible and speech and mastication difficult. The parts previously described continued swollen. The condition gave rise to but little discomfort, although the inconvenience of being unable to put on his clothing and shoes and the inability to use his hands incapacited him for his routine duties.

Physical Examination.—On the third day, that of admission to the hospital, the swelling subsided to some extent. The patient was 5 feet and 10 inches in height, weighed 175 pounds, and though not robust was not of an unhealthy appearance. All organs such as the eyes, ears, heart, lungs, and abdominal viscera were free from any palpable abnormalities. The eyelids exhibited an appearance such as one might expect in an edema the result of an acute diffuse nephritis. The cheeks and skin of the neck were puffy, but did not pit on pressure, while the tongue was grossly thickened but otherwise normal. The skin of the chest and abdomen, while of a fine texture, appeared thickened. It was somewhat blanched, dry and tense, with slight pitting on pressure. The skin of the upper and lower extremities presented much the same general phenomena, but the feet and hands were shiny, having a tense, slick appearance. They felt cold and clammy, and were a dark, dull, purplish red, with here and there a bit of white mottling. Moderately firm pressure resulted in some pitting, lasting from one to three minutes, while the subsequent blanching disapof light is thrown on it. We always test that for ourselves, and it sometimes helps us in determining by further examination some past forgotten illness. It should help us when we come to determine the correction. It is very seldom that they report on the stippling of the macular region which dates back in a nephritis of pregnancy of years ago. It is seldom that they note the slight traces of an old neuroretinitis. You complain that the optometrist has invaded your field. The competent ones frankly treat the eyes as optical instruments and claim to do nothing more. Many of you, for the average case, do nothing more. Of course you do protect the patient in the case of some eye diseases which the optometrist would not be expected to discover; but that is the very least that you can do.

METHODS OF REFRACTION

And now please allow me to speak of your methods of refraction. I know that this is not the field of the internist; but it is his patient whom you are examining, and he is intensely interested that you succeed. His difficult cases form so small a percentage of your practice and take so much of your time that you would often prefer not to bother with them. But they are the most of our practice, and we need your help. We ask you, therefore, to consider refraction as the highest expression of your art, not as a necessary evil to be endured or handed over to a junior associate. Give it your best thought. Please be patient; your responsibility is great. We know often from watching you whether or not you will succeed with our patient, so pardon us if we ask you to consider these suggestions.

To begin with, it is fundamental that you first of all determine accurately the static error and all of it. Don't worry: we shall not ask you to correct all of it; but we do ask that you determine all of it before you plan to correct any of it. To do this requires complete paralysis of the muscles of accommodation. Homatropin may be satisfactory for the patients who come to you directly. I don't know anything about them; but if correction is intended to correct more than blurred vision, please use atropin, if possible. We think your use of cycloplegics is often a good deal of a farce. We ask you to determine the entire error, no matter how slight it is, no matter whether it disturbs vision or not, no matter whether you think it important or not. Those ophthalmologists who have helped us most always begin with a careful retinoscopic examination in order to get the general lay of the land and to guard against a gross error which the patient has learned to suppress. They insist that the distance from the patient when the retinoscopy is performed
hould be accurately measured and not estimated each
e. Then, as the court of last appeal, they use the
ective tests to confirm this result and add details.
comes the question of muscle balance, muscle
h, ciliary hypertrophy, etc.

is point I would urge you not to fatigue the
o much. In colorimetric work we do not
tudent to use one eye more than fifteen
time, and require that he determine this
ely with a watch. While the fatigue
ction test may not be as rapid, yet we
is important and does explain some
arder some of our friends try, the
; for the more pains they take,
they work, the more fatigued
he static error accurately determined, the tests repeated and checked up, then the question arises, How shall we meet it? and in answering that please allow us some voice. The formula of the error does not mathematically determine the formula for the glasses. Three men agreeing on the error might differ markedly in the glasses they would prescribe, and their differences would probably depend on their estimation of the patient, and we know our nervous patient much better than can you. In the case of your average patient you may follow certain general rules with average good results. But these cases I am now discussing are not average cases, and we internists who have examined them as individuals, not as seeing mechanisms, know well that you can make or break our chances of helping them. Some of these patients are hyperesthetic, some rather anesthetic; some are hypertonic, some more atonic. I remember one ophthalmologist who watched the patients as they walked to his chair, noted their stride, their posture, their snap; who pinched their arms to determine their muscular tonicity, and who talked to them to form some estimate of their mental tone. Do you? We have struggled with these same persons before we referred them to you. Cannot ophthalmologist and internist talk over the patient and together decide concerning the correction to be prescribed? You will need to teach us a great deal before we can help you much, but we are confident that if you will teach us how we can help them our patients will profit much as a result. Tonsils are no longer a local problem. The specialist in diseases of the throat has learned to discuss them in terms of heart, joints and kidneys. The nose is no longer entirely a local problem, for the rhinologist now consults with internists concerning the patient's asthma and dysmenorrhea. The internists now are struggling to relieve patients with neurasthenic reactions, and we ask you to come over into the field of neurologic ophthalmology and help us.

NECESSARY BUT OFTEN NEGLECTED REFINEMENTS IN EXAMINATION OF OCULAR REFRACTION *

WALTER L. PYLE, M.D.
PHILADELPHIA

The examination and correction of errors of ocular refraction may be called an art. Preparatory scientific study is, of course, necessary; but without the proper mental attitude—an absolute belief in the importance of correcting small refractive errors, the best work is not possible. Long practice, infinite care, and attention to finer details are imperative requisites. It is an established fact that many of the worst sufferers of ametropic eyestrain are the subjects of small optical errors. Astigmatism is the important defect, and on its proper diagnosis and treatment rests most of the ophthalmologist's success.

A slight fault in the correction of refractive errors aggravates rather than relieves the accompanying asthenopic symptoms. By applying sufficient optical aid to allow the ciliary muscle to compensate perfectly for the uncorrected refractive defect, continuous rather than intermittent ametropic eyestrain is established.

---

* Read before the Section on Ophthalmology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

THE TRIAL FRAME

The prime requisites for the trial frame are rigidity, lightness, proper position on the face, and ease of general adjustment and manipulation of the trial lenses. There is also a necessity for individual adjustment of the two sides, to permit perfect binocular centering. The ideal trial frame would also allow independent bilateral, vertical and anteroposterior adjustments; but this would necessitate too much mechanism, and would be too expensive and too heavy. Such complicated construction is not necessary in ordinary office work.

It is most important that the trial frame shall be firmly and snugly placed on the sides of the nose and adjacent cheeks, in approximately the position in which the prospective spectacles or eye glasses will be worn. In this respect all frames fixed to mechanical instruments, such as optometers, are at fault, are often clumsy, and are signally deficient for accurate testing. The frame should be grooved and slotted to allow rotation of the cylinders at least 180 degrees. The rotation should be effected by light contact with the tip of the first finger. It is impossible to practice noiseless and smooth rotation, when using cells without handles. The placing of the trial lenses in the spring clips is awkward, disconcerting to the patient, and trying to the oculist. Only by the use of a properly grooved and slotted trial frame can the ideal examination of the refraction be made.

The ordinary trial frames seldom conform to the modern standards of skilful medical refractionists. In hospitals and dispensaries they are especially faulty and often ludicrous. For many years I used one of three trial frames made under the direction of Dr. George M. Gould. In 1917, I showed to this section a modification of this trial frame conforming to the modern requirements, but it was lacking in the necessary central universal adjustment. Last year, I exhibited at a meeting of the American Ophthalmological Society an improved trial frame having a universal vertical and horizontal adjustment by rack and pinion, placed in the center of the frame, permitting adaptation for any peculiar facial conformation.

The frame is grooved for two lenses. The front groove, for the cylinders, is slotted to allow rotation of the cells with handles. A third test lens may be placed in front of the frame, resting on three small hooks. The test lenses, carefully centered, should be placed before the eyes, properly inclined, and just clearing the eyelashes. The bridge of the frame should not wound the skin or cause irritation or pain. Rotation of the cylindric lenses must be easy, silent and unnoticeable, to prevent even momentary diversion of the patient's attention.

The bilateral independent adjustment is effected by two double screws, operated on the upper outer sides of the frame. The frame is placed on the face, quickly set by the universal adjustment, and supplemented when necessary by movement of the independent double screw adjustment, until the lenses are properly centered. Broad shell coverings on the inner sides of the two cell holders permit the snug application of the frame to the sides of the nose and cheeks. The nose piece proper is used only to fix and maintain the proper position. The graduated semicircles are enameled in dull black, and marked with distinct white lines and figures, allowing the maximal ease in reading the axes. The whole frame is finished dark and dull to prevent annoying reflections.

CYCLOPLEGICS AND MYDRIATICS

Unless they are contraindicated by age or disease, I always use a cycloplegic and mydriatic in the examination of refraction. Cycloplegia permits study of the static refraction, and mydriasis facilitates retinoscopy and ophthalmoscopy.

My routine custom is to instil from 1 to 6 drops of a solution containing homatropin hydrobromate, 2½ grains; cocain hydrochlorate, 1¼ grains; distilled water, 2 drams. I use this cycloplegic personally and exclusively in my private office, and never prescribe it for home use. If more than 1 drop is necessary, I instil the additional drops at intervals of fifteen minutes. I seldom use more than 4 drops. The cycloplegia may be partly corrected by the instillation of 1 drop of a 0.5 per cent. solution of physostigmin salicylate. Beyond a sense of slight twitching, there is no objection to the counteracting drop. In many thousands of cases, I have never seen severe untoward results from inducing cycloplegia according to the foregoing method.

Only occasionally for therapeutic purposes do I ever use a stronger cycloplegic; and then I prefer a 1 per cent. solution of atropin sulphate.

1931 Chestnut Street.

THE PRESENT STATUS OF REFRACTION WORK *

E. J. GARDINER, A.B., M.D.
CHICAGO

Following the track sparsely blazed by Young, Whewell, Ware and Airy, Donders cleared the ground and laid the foundations of modern ophthalmology. The obstructions in his path were many and formidable, but his genius enabled him to surmount them, and his epoch-making book on "Accommodation and Refraction of the Eye" at once raised ophthalmology from a purely empiric practice to a quasiexact science. When one considers that up to his time the true nature of hypermetropia, myopia and astigmatism was unknown, that asthenopia was classed as a disease, and that the instruments at his disposal were few and crude, one marvels at the mind that was able, out of this slough of ignorance, to evolve a science that immediately placed ophthalmology at the forefront of the medical specialties. How accurate and exhaustive were his investigations, and how sound were his conclusions is evidenced by the fact that although, since his day, a complicated superstructure has been raised on the foundation that he laid, not one stone thereof has been removed.

Since the publication of Donders' work until the present time, the ingenuity of ophthalmologists has been hard at work improving old instruments of precision and devising new ones, with the result that today our armamentarium is so extensive that there are few problems pertaining to the detection and measurement of muscle anomalies and errors of refraction for the solution of which there are not one or more excellent devices.

The question is, What are we doing with this rich heritage? Are the scientific principles and practical instructions handed down to us being applied in our

---

* Read before the Section on Ophthalmology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

refraction work? I do not think that I am violating the canons of modesty when I assert that in no other country is better refraction work done than in the United States. The correction of the minor forms of astigmatism, with all the benefits that it confers, is more common in this country than elsewhere. And if I mistake not, the original advocates of the use of the quarter diopter cylinder were Chisolm and Gould, both Americans. Foremost among the investigators of the anomalies of the ocular muscles stand Stevens and Howe, and the latter's work, "The Muscles of the Eye," is the most comprehensive and exhaustive treatise ever published on the subject.

In recent years we passed through a rather sharp epidemic of muscle cutting; but that has blown over, and today more conservative methods prevail. The nonsurgical treatment of convergent squint is becoming more common, and in consequence, cases of postoperative exotropia are less frequent. Opticians tell me that bizarre prescriptions are less common than they were ten or fifteen years ago. Such gross errors as a + 1 sph — 1 cyl ax 180, are rare, but the more confusing combination of a + 1 sph — 0, 75 cyl ax 180 are still seen sometimes. More men are realizing that in ametropia the disturbed relations between accommodation and convergence play an important rôle in the causation of asthenopia, and that the study of the relative range of accommodation and convergence is not a "laboratory stunt," as it was at one time wont to be called, but an important factor in the problems of refraction work. There is a wider recognition of the fact that many of the phorias are the direct result of disturbances between these two functions, caused by ametropia, and that the sane procedure is to remove the cause rather than treat the effect thereof.

Taking these facts into account and further considering the excellent work being done by some of our leading men, we might deem the present status of refraction work eminently satisfactory. But the only trouble is that there is too much bad work mingled with the good; for it must be acknowledged that there is a lot of careless refracting being done, and some of it in places from which better things should be expected.

Examining the causes of this evil, we find that ignorance is responsible for the largest quota; but after making allowance for bad work due to inadequate training, a considerable percentage remains to be accounted for. Let us for a moment look into the causes of this percentage.

Strange as it may seem, we have to class among the fruitful causes of bad work the very means that enable careful and judicious observers to obtain their best results, namely, measuring devices. Ophthalmic measuring instruments are apt to fascinate the inexperienced observer, tempting him to surrender his judgment to their mechanical accuracy and deem their findings conclusive. The power of this fascination is to be seen in the tendency noted in some quarters to reduce refraction work to a quasimechanical process. The late Dr. John Murphy, in contending against this tendency as it affected surgery, used to say to his assistants, "Gentlemen, please remember that a diagnosis is made with the cortical cells, not with instruments."

Now, I do not impugn the use of devices for measuring refraction and muscle balance; they are indispensable, for they furnish us with data obtainable in no other way. But these data, as they apply to a given case, must be interpreted and this work must be done with the "cortical cells," for at times it is a problem requiring careful study and nice discrimination.

When, in the laboratory, instruments are used to investigate the properties of matter, their findings may be considered conclusive; but when, in the office, devices are employed to ascertain the muscular balance and the refraction of eyes, their findings are not conclusive, for their significance is modified by the general condition, special characteristics and idiosyncrasies of the person to whom the eyes belong. Two patients might each have a card with identical data regarding their refraction, accommodation and muscular conditions, but it does not follow that the two patients should be treated alike. One of them might need, in addition to the correction of his ametropia, orthoptic exercises, reconstructive or sedative medication and complete rest, while the other might be immediately relieved of all his troubles by a pair of glasses. In the practice of ophthalmology, as in the practice of medicine, the study of the individual is paramount.

Another factor in the production of poor refraction work is the plan, adopted by some oculists, of delegating this part of the work to young assistants, and in some instances, even to office attendants barely initiated into the rudiments of the science. When we consider that, because of the preponderance of refraction anomalies over other forms of ocular disturbances, this work more abundantly contributes to public efficiency by enabling children to acquire an education and fitting them, when older, to earn their living, and by preventing certain incapacitating eye diseases resulting from continued eye strain; its importance is so obvious and the results depending on its proper performance are so momentous, that delegating it to inexperienced hands seems like a sin against the public weal. Unless an assistant is thoroughly trained and has wide experience in this work, it would seem much wiser for the head man to do the refracting and to delegate to an assistant the routine treatment of cases.

If it is answered that the assistant's findings are carefully supervised, the reply is, that adequate supervision is equivalent to doing the work over, with the consequent loss of time, and that inadequate supervision is simply placing the mark of approval on what may be, and in the circumstances probably is, bad work.

Regarding the practice of eliminating the use of cycloplegics and of correcting the manifest error, I would say only that in my estimation it lacks the main elements of true scientific work. It is true that it has received the *conditional* sanction of some of the great masters, but somehow the sanction does not seem to harmonize with the precepts elsewhere given in their books. I realize that circumstances arise when fitting glasses in this manner is the alternative to doing nothing; but the patient should be warned that it is simply a provisional expedient and that the full examination should be made at the earliest possible moment. The only things that can be said in its favor are that it pleases a certain class of people by catering to their prejudice against the use of "drops," and that it is a quick and easy way of disposing of the case. But it should ever be borne in mind that in neglecting to ascertain the total error of refraction, the work is transferred to the field of conjecture. If the patient is 40 or more years old, this field has become so limited that one can fearlessly venture to estimate its boundaries; but in children and persons under 25, the manifest error gives no certain indication of what may remain latent

In the moderate and high degrees of hypermetropia, the accommodation that masks the latent part of the error, taken in relation to the convergence necessary to maintain singular binocular vision, is responsible for most of the disturbances that bring the patient to the oculist. Correction of the manifest hypermetropia simply lessens the struggle of accommodation and convergence by the amount in meter angles corresponding to the dioptric power of the lenses prescribed. Why the normal relations between these two functions should not be at once restored, so far as they can be with glasses, is a question that the advocates of this method of refracting have never answered satisfactorily.

The tedious process of repeatedly changing glasses to correct the gradually increasing quota of manifest error seems to me both unnecessary and unduly hard on the patient's pocketbook. A young patient having a total hypermetropia of 4 or more diopters, with an absolute manifest of 1 diopter, usually has a long road to travel and many glasses to purchase before the ultimate goal is reached. The optometrists have not been slow in seizing the opportunity to instance the advocates of this method in pushing their claims for legislative recognition, alleging that the optometrists use the same method in fitting glasses.

The foregoing remarks may be classed under the head of personal opinions, and as such they are open to discussion. I do not entertain the hope that my comments will in the least affect the methods of those of my colleagues that happen to differ from me in opinion. My main object has been to point out to my younger colleagues some of the things that my experience has taught me to regard as pitfalls in the road to the accomplishment of good refraction work.

Let us now consider ignorance—or should I call it lack of adequate instruction—the source from which the largest percentage of bad work emanates.

It is well known that there are a large number of men practicing ophthalmology who neither by nature, education nor training are fitted for the work. If, with similar lack of fitness, some of these men were put to work in a factory where their jobs were inspected, their places would soon be vacant. But the blunders of medical men are not subject to inspection and have to be endured by the patient, until perchance he falls into the hands of a man who understands his business but who is deterred by ethical reasons from exposing the ignorance of his brother physician.

How prevalent is this lack of training was disclosed at the conclave of the American College of Surgeons held in Chicago in 1917, when the director reported that in the examinations held for fellowship in the college, the poorest papers were presented by the eye, ear, nose and throat men, and that only 2 per cent. were admitted to fellowship.

In days gone by, the excuse for ignorance was the lack of educational facilities. This allegation was true to a certain extent; but even when opportunity for instruction was offered, it either was not embraced or was embraced in such a perfunctory and indifferent manner that it was profitless. Especially was this true of the study of refraction.

My interest in teaching this branch of the specialty dates back many years. Under conditions more or less favorable, I have made five attempts to establish postgraduate courses in refraction. They were all failures because the men were not interested in this part of the work. My clinics and the operating room were always crowded, but on refraction days there was always room to spare. Indeed, and this is significant, the students seemed more interested in watching the assistants fit glasses than they were in learning the properties of the glasses and the nature of the anomaly that they were being fitted to correct. As one of them, who had been practicing ophthalmology for several years, put it: "You talk about a lot of things that I don't understand and that don't interest me. Those fellows out there are doing real practical work; and I am a practical man." I might add that a few days later in my clinic, this "practical man" diagnosed as plastic iritis, a typical case of acute glaucoma.

Within the last few years, things have changed for the better in the matter of opportunities for studying ophthalmology. There is now little excuse for ignorance, and it is to be hoped that in the near future ignorance on this subject will be inexcusable.

The University of Colorado School of Medicine has established a course in ophthalmology under the direction of Dr. Edward Jackson of Denver. The minimum term is one year, with the advice to extend it one year longer. On passing a satisfactory examination, a diploma of Doctor of Ophthalmology is conferred. The University of Minnesota Medical School also has a one-year course in ophthalmology and confers a degree of Doctor of Ophthalmology. Both these institutions offer a thorough course of instruction in physical and physiologic optics, refraction and accommodation, and muscle anomalies.

The American Board of Ophthalmic Examiners, acting in conjunction with the American College of Surgeons, is endeavoring to sift the good from the bad by holding examinations and issuing certificates to men who have proved their fitness to practice ophthalmology. As this board acts as the committee on credentials of the American College of Surgeons, its certificate entitles its possessor to fellowship in the college.

I am informed that the examining board is not overburdened with work. This was to be expected. A certain class of medical men have been drifting for years into ophthalmology, most of them through the door of six weeks' postgraduate courses. They have been practicing the specialty to their own satisfaction and profit, caring little whether or not their qualifications were brought into question. Is it reasonable that such men shall of their own free will submit to an examination which they feel themselves unable to pass? It would be absurd to expect such a thing. It is to our younger men that we must look for the realization of all hopes for higher standards. To enable these men to obtain adequate training in ophthalmology, it will be necessary that more of our medical colleges follow the noble example set by the University of Colorado and the University of Minnesota.

Further, as a protection to men who have taken the pains properly to fit themselves for the specialty, postgraduate schools and institutions devoted to the treatment of eye diseases should refuse to give certificates for a few weeks' attendance, should establish courses of at least four months in which all the branches of the specialty should be taught, and should require a satisfactory examination in all these branches before issuing a certificate. I fully realize that such an innovation would seriously affect some institutions, but if the standard is to be raised and men working to attain this standard are to be protected, it will be necessary to "hew to the line, let the chips fly where they may."

To encourage the establishing of schools of ophthalmology in our medical colleges, and to induce the managers of postgraduate schools and of eye institutions to adopt longer and more thorough courses of training would require the cooperation of the medical fraternity at large. This cooperation could be secured, I believe, by a concerted propaganda carried on by our national, sectional and local ophthalmologic societies.

Without the cooperation of the medical profession at large, little or nothing can be accomplished. So long as incompetent men that drift into ophthalmology by a cheap and easy short cut are put on a par with men who have traveled the hard and costly road, there will be little inducement for the latter to make the effort. But if medical men would lend their aid by giving preference to these worthy young fellows, not only would many more of them strive for the highest standards, but also, it would induce others, who hitherto have cared little about standards, to improve themselves and apply to the Board of Ophthalmic Examiners to prove their competence and their rights to the confidence of their professional brethren.

CORRECTION OF THE MUSCULAR ANOMALIES OF THE EYES

SECOND IN IMPORTANCE ONLY TO THE CORRECTION OF THEIR FAULTS OF REFRACTION *

SAMUEL THEOBALD, M.D.
Clinical Professor of Ophthalmology, Johns Hopkins University, Medical Department; Ophthalmic Surgeon, Johns Hopkins Hospital and Baltimore Eye, Ear and Throat Hospital
BALTIMORE

Unless my experience in dealing with asthenopia is very exceptional, and the deductions drawn therefrom entirely misleading, ophthalmic practitioners, as a rule, are inclined, it would seem, to minimize the importance of the muscular anomalies of the eyes, and to lay relatively too great stress on their refractive faults as etiologic factors in this condition.

This conviction, if I may call it such, is due, in considerable measure, to the fact that in asthenopic patients that come into my hands after having been given glasses by other ophthalmologists, it is so often found that, though great pains evidently have been taken to correct even minor faults of refraction, grave muscular errors have been entirely overlooked, or, if detected, have been ignored in the glasses prescribed.

Then, let one turn to the tables of "affections of the eyes treated" in the annual report of almost any ophthalmic hospital, and note the striking contrast between the large number of cases of anomalies of refraction and accommodation and the insignificant number of latent muscular faults there recorded. For example, in a recent report of a well-known hospital for diseases of the eye, ear, nose and throat, I find under the heading "Anomalies of Refraction and Accommodation" 2,819 cases tabulated, while I fail to find in the tables mention of a single case of latent muscular fault, a single instance of heterophoria. In another report of the same institution, I find four cases of exophoria recorded—no mention being made of other latent muscular faults—while 1,340 cases of anomalies of refraction and accommodation are included.

The report of another eye and ear hospital, one of the largest and best known in the United States, shows a similar, marked contrast—10,854 anomalies of refraction and accommodation are mentioned, and only twenty-three cases of latent muscular faults, five of esophoria, eighteen of exophoria and one of hyperphoria. Quite as remarkable is the fact that during the period covered by this report, in which only these twenty-three cases of heterophoria were observed, there were recorded no less than 537 cases of convergent and divergent strabismus. A later report of this same institution, made in 1917, gives 7,581 refractive anomalies, 541 convergent and divergent squints, and only three cases of heterophoria, while the report for the same year of a well-known hospital for diseases of the eye, ear and throat, in New York, records 2,849 refractive anomalies, 283 cases of strabismus, and only two cases of heterophoria.

The inevitable conclusion to be drawn from these figures, it seems to me, is that in these institutions, and not improbably in the majority of similar institutions throughout the country, the latent muscular faults of the eyes—and it is, of course, these *latent* faults, not the manifest faults, the squints, that give rise to asthenopia, headaches, etc.—are in large measure ignored in the routine examinations of the eyes of patients who apply for the relief of asthenopia.

The disposition on the part of so many ophthalmologists to underestimate the importance of the muscular faults of the eyes and to center their attention on the faults of refraction is, I believe, due chiefly to the fact that muscular imbalance is not infrequently largely, and sometimes wholly, dependent on errors of refraction, and is lessened or may be entirely done away with when these errors are corrected by suitable lenses. This circumstance, indeed, has led certain extremists to deny the existence of "muscular asthenopia," and to contend that this condition is, in all cases, due to a refractive fault, and is eliminated by the correction of this fault. And, it may be added, there are also extremists—very few, it is true—who hold exactly the opposite view, who insist that muscular imbalance is in nowise dependent on anomalies of refraction—manifestly a still more bizarre conception.

While the views of these extremists do not deserve serious consideration, it has seemed to me well worth while to utter a word of warning against what I believe to be the present trend of ophthalmic practitioners to belittle the importance of these latent anomalies of the ocular muscles.

The point that I wish to emphasize is, as I have said before,[1] that "although heterophoric conditions, because less common, are not so frequent a cause of asthenopia as are errors of refraction, they are quite as capable of producing the manifold symptoms, local and remote, which we have learned to attribute to eyestrain." And further, that "while it is true refractive errors, when present, markedly influence . . . muscular faults, there are muscular faults . . . which are in no sense dependent upon ametropia, and which start are evidently due to disturbance of the exterior muscles of the eye, and in that case treatment of the latter should be initiated at once.

---

* Read before the Section on Ophthalmology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

[1] Theobald, Samuel: Prevalent Diseases of the Eye, Philadelphia, W. B. Saunders Company, 1906, p. 466.

Dr. W. W. Kahn, Detroit: Formerly we sent our patients to the internist, and now the internist sends them to us. We have reason to congratulate ourselves on the energy and the proficiency obtained in our work. Dr. Emerson's paper gives the thought that the eyestrain symptoms are closely connected with the bodily health. In order to get our best results in refraction, it is absolutely necessary that we see that the other troubles in the patient are corrected. I try to cooperate with our general practitioners and specialists to get the patient into the best possible health, and in that way to get the best results through refraction. There are no anastigmatic eyes. Dr. Gould himself says he never saw an anastigmatic eye.

Dr. Sidney L. Olsho, Philadelphia: I have used a trial frame like Dr. Pyle's. In certain respects my trial frame differs slightly.

(Dr. Olsho gave a blackboard demonstration of his trial frame. A full description will be published in the transactions of the section.)

Dr. John Green, St. Louis: Since I have been systematically using Lancaster's charts I am convinced that I determine the axis and strength of the cylinder with greater accuracy than ever before. After all, it is the postcycloplegia test which determines the prescription, and it is precisely in determining the exact axis of the cylinder under these conditions that Lancaster's charts excel. It is a truism that the axis "under drops" and the axis "after drops" may differ. With Lancaster's charts it is possible with most patients to determine the axis within five degrees and the strength of the cylinder to from 1 to 8 diopters. I question very much whether the method of determining the precise axis by having the patient observe the gaps in small letters and indicate the "stop" point of a rotating cylinder can be equally exact.

Dr. William H. Wilder, Chicago: The older members of the section will recall the time when we asked the internists to recognize the fact that headaches may be produced by such a mythical thing as eyestrain. We must not forget the fact that ophthalmology is only a branch of medicine, and that the eye is not differentiated from the other organs. It behooves every ophthalmologist to remember that he is also a physician, and that he must take and study the case as a whole. Headache is a symptom with which we must reckon. These headaches take place in a class of individuals who have nerve fatigue. The individual's nervous balance is upset, and we must try to straighten it out and save him from a fall. When we have convalescence from a serious disease, we cannot give the patient tasks to perform which he might do when in normal health. And here I offer a word of suggestion to the internist, not to imagine that these patients can use their eye muscles as readily as they did in health.

Dr. C. J. Savage, Nashville: I will refer to some cases of muscular errors in which existed cyclophoria, a condition not mentioned in any paper or discussion so far this morning. A man who had, in spite of difficulties, grown to be a great banker, found himself confronted with an offer of a high position in a New York bank. He knew the physical condition of his eyes was such that he could not undertake the greater work. These were his errors, as I found them: Left hyperphoria 4 degrees plus cyclophoria 8 degrees, and exophoria 14 degrees. The complication of plus cyclophoria was the condition which made him carry his head toward his right shoulder, in which position he could see single with his two eyes. With head erect he had double vision, and the doubling was worse if he attempted to carry his head toward the left shoulder. I did a nasal marginal tenotomy of the left superior rectus, and a central tenotomy of the left external rectus. From that time to this he has been comfortable in the work of his new position. Another man had since childhood been wholly unable to maintain binocular single vision, the right eye being the one which would turn always directly out. The monocular phorometer showed him to have exotropia of 26 degrees and plus cyclotropia of 17 degrees. I made an upper marginal tenotomy of his right externus, and ten days later made a right marginal tenotomy of his left externus. Following the first operation there was binocular single vision, which was made easier by the second operation.

His cycloexotropia has been transformed into practical orthophoria. He has binocular single vision at all times, and is comfortable in his work. The cyclophorometer still shows probably 2 degrees of plus cyclophoria. A third man, an army surgeon, was wearing a plus one and one half prism base down for the right eye, and also a plus one and one half prism, with base up, before the left eye. With a monocular phorometer I found him without any hyperphoria, perfect balance of the vertically acting muscles. He had 6 degrees of exophoria in the near, and the cyclophorometer showed him to have 70 degrees of plus cyclophoria. I did an upper marginal tenotomy of both externi. Five hours after the operation, he had no cyclophoria at all. The Maddox rod is wholly useless in testing the recti muscles, but constitutes the very best test for imbalance of the obliques, that is, after cyclophoria.

Dr. H. B. Lemere, Omaha: Patients are sometimes exhausted and suffering from symptoms. That is why they come to you. You give them a test chart with the light coming through frosted glass, with black letters on this glass. You are going against all laws of illumination. How can this be remedied? The test chart should be illuminated by indirect lighting. I made such a chart with a draughtsman's board, two lights and two parabolic reflectors. The light in every meridian is the same. There is no shadow from any object erected in the middle of the chart. Many cases of refractive error change from day to day and from week to week, and these cases under most complete cycloplegia will change both in the axis of the correcting cylinder and in its amount. What is this change due to? It is not due to the ciliary muscle. In the large percentage of the cases I have found these cases show minute changes in the macular region, causing the variations in refraction. This condition will be overlooked unless the macular region is inspected very carefully. The ophthalmoscopic examination must be made after the subjective test; otherwise a scotoma from such an examination of the macula as I have found that about three seconds' observation of the region are necessary to observe the changes.

Dr. Linn Emerson, Orange, N. J.: This symposium on refraction would not be complete without registering a protest against the so-called library and Windsor style of frames. With the objection to spectacles, it is entirely artificial, as we all remember that 10 years ago we could not get young women to wear spectacles. They insisted on glasses because they were more stylish. Now, all the girls will go out and get a pair of these ugly library spectacles. Why? Because they are fashionable. The lenses are too large and widely separated, particularly if they are bifocal. And what is worse than all the rest is those lenses turn in the frame. If you must wear them, make the lenses slightly oval so they cannot turn, or that the lenses may be marked at the hinge, so that they can be seen to be out of proper axis when such is the case.

Dr. Oliver Tydings, Chicago: The whole question is one of diagnosis. The man most accurate in diagnosis finds fewer of those cases. A patient had intolerable headaches for three or four years, and they were absolutely relieved by removal of the tonsils. As to cycloplegias, I have used scopolamin almost exclusively in my practice. Where I cannot use scopolamin, I use atropin; but you can get as good results from scopolamin in three-quarters to one and one-half hours, as you can get from the use of atropin in 56 hours. I fully endorse what Dr. Savage said about the Maddox rod, and what Dr. Theobald said about the necessity of accurate muscular measurement.

Dr. Dunbar Roy, Atlanta, Ga.: I agree with Dr. Emerson's view in the main, but he has not gone far enough in suggesting a remedy. The reason why some ophthalmologists relieve their patients by the fitting of glasses is the fact that they study the individual in all his or her environments, not simply as an eye case. This efficiency is obtained by long experience. I agree with the essayist that it is the low degree of error which produces the neurotic symptoms. In advancing the plea for a more thorough use of atropin, I think he is wrong unless he qualifies it by having the examination made after the mydriatic effect has entirely subsided. Patients and doctors are not willing to wait. Homatropin is not a cycloplegic in the true sense of the word. If you want to examine an eye where the accommodation is paralyzed you must use atropin. If you only want a mydriatic you can use homatropin unless the pupil is too small for one to use retinoscopy or to get a clear image with the ophthalmoscope. When a cycloplegic is needed it is atropin. I rarely use either in patients over 20 years of age. When a patient needs glasses he needs them when his eyes are in their natural or normal condition and not when the muscle of accommodation is partially paralyzed. This is the reason why opticians so frequently fit patients with comfortable glasses where the ophthalmologist has failed. Another great trouble is the having of a fixed distance to which reading glasses are fitted. Some patients want a close focus in their work, others want a very long focus. This idea that the reading distance for every individual must be at 12, 13 or 14 inches is wrong. The workman who only reads the evening papers and uses his glasses for driving nails and putting names in his day book on the counter, does not need a glass like the student and architect, who must see every line and angle in his work. For distant glasses the patient needs glasses for infinite distance, not 20 feet. Twenty feet is not infinite. Let him go to the window and look out for two blocks away and see if the glasses suit him. Another feature which is wrong. The big trial frames are a nuisance. I am sorry to see Dr. Pyle refer to those cumbersome trial frames as pictured in his paper. They are a nuisance and should be abolished. The patient is more concerned with the heavy frames on the nose than he is about the acuity of vision. He does not know which is the discomfort, the glasses or the frames. Have a swing frame in front or a one groove aluminum. The essayist is right. Work with the internist but use more common sense in doing your refractive work.

DR. A. E. DAVIS, New York: I have been especially pleased and instructed by the paper of Dr. Emerson, who has emphasized the fact that the eyes are something more than two optical instruments set in the front of the head. The eyes are indeed a vital part of the complex organism of the entire body and in fitting and adjusting glasses we should bear this point in mind. His description of those cases of eyestrain associated with sick headaches, migraine, the phobias, etc., is highly illuminating and his insistence that in such cases the combined efforts of both the ophthalmologist and the internist are required, is sound teaching. In these exceptional cases I am in entire accord with the dictum that the entire static error should be ascertained by the full use of a true cycloplegic, as atropin or scopolamin and not the use of the so-called cycloplegic homatropin. In such cases all the objective tests should be made and then the crucial subjective tests, including muscle balance. The tests should not be prolonged too far at a single sitting, unless, as Dr. Emerson says, the patient becomes fatigued. In such instances the patient is uncertain what he does see, and I may say, the examiner is often uncertain of what he is trying to do. In the ordinary refraction patients above fifteen years of age, I do not use cycloplegics as a routine procedure, reserving cycloplegics for exceptional cases where there are indications of spasm of accommodation in children in squint cases, and in the class of cases spoken of by Dr. Emerson. In reference to the point made by Dr. Gardiner that no satisfactory answer had been forthcoming, why in high degrees of hypermetropia the normal relations between convergence and accommodation should not at once be restored so far as they can be with glasses (full correction), is a question that the advocates of a partial correction of the hypermetropia have never answered satisfactorily. I may say that Landoldt answered this question long ago when he showed that the ciliary muscle could work comfortably with only one third of its power in reserve, whereas the converging muscle must keep two thirds of its power in reserve. In all cases with rare exceptions I test the muscle balance. However, I give prisms only for the correction of vertical deviation.

DR. CHARLES P. EMERSON, Indianapolis: One of the chief duties of a teacher of internal medicine is to disabuse the minds of his students of the use of those terms which we call "semaphore" phrases. They stop a train of thought. Such words are migraine, neurasthenia and cycloplegia. To judge of the asthenia of the patient is my function, and while it might be desirable for the ophthalmologist to get some idea of whether his patient is thenic or asthenic, it took us two or three hours to do so, and you should ask us concerning the results of the nervous reactions of this patient, and then you should confer with us as to whether those particular symptoms should be corrected by eyeglasses, or whether we should proceed farther in seeking for the cause of eyestrain. Some of the cases have been those of asthenia, and you have told us they were cases of ciliary hyperatrophy. You told us these cases were the ones in which we required repeated attention in giving them what was desired.

DR. WALTER L. PYLE, Philadelphia: It is a great satisfaction to hear from a well known internist such an excellent exposition of the problems relative to eyestrain. Dr. Emerson's fear of the narrowness of the specialty of ophthalmology will soon be unwarranted. From my experience in private consultations and professional meetings, no specialist is finding closer or more numerous interrelations with the whole science of medicine and surgery than the oculist. In ophthalmic meetings no subject is more popular than medical ophthalmology, or neuro-ophthalmology; and some of the established methods of medical diagnosis have been elaborated chiefly by observations and experiments of ophthalmologists. Dr. Emerson's warning against "overkeenness of vision" is significant of too frequent overcorrection of myopia or undercorrection of hyperopia, circumstances which should never occur if preliminary cycloplegia is used, and proper methods of examination of refraction employed. Dr. Emerson issues a very proper plea for personal work in the examination of refraction. I always do my refractive work personally. In regard to the invariable use of atropin, I do not believe that this is wise. Prolonged cycloplegia and mydriasis often greatly interfere with the best subjectice examinations. A more transient cycloplegic such as homatropin, used in the manner I have stated, generally gives better results, and more often makes evident the complete optical defect sooner than the old fashioned prolonged use of atropin. I agree with Dr. Emerson that each patient should be studied individually, and that the proper prescription for lenses should be determined only after a consideration of all the associated physical, physiologic and psychologic elements. I am in general agreement with Dr. Gardiner's statements. With few exceptions, I am in accordance with Dr. Theobald. In every case, I measure and record the heterophoria. These records are always preserved with those of the optical examinations. The report of the Committee on Ocular Muscles gives striking evidence of the thorough and deliberate way in which they are studying the pertinent questions of this unsettled subject.

DR. EDWIN J. GARDINER, Chicago: I want to insist on the use of a cycloplegic for thorough paralysis. A case is not refracted unless accommodation is paralyzed. Unless you have the accommodation paralyzed you cannot get the combinations of the ciliary nerve with the external muscles of the eye. The physician should have the full condition reported, and he cannot report the full condition without that information.

DR. SAMUEL THEOBALD, Baltimore: A number of those who have read the papers and spoken on the subject have mentioned that they used the Maddox rod—I suppose we all mean the multiple Maddox rod—in testing the lateral muscular balance. I want to protest that the multiple Maddox rod is the ideal test for vertical hyperphoria. I believe it is absolutely misleading and untrustworthy when used for testing the efficiency of the lateral muscle.

PROCEEDINGS OF THE ATLANTIC CITY SESSION

MINUTES OF THE SEVENTIETH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT ATLANTIC CITY, JUNE 9-13, 1919

(*Continued from page 1769*)

HOUSE OF DELEGATES

Third Meeting—Tuesday Morning, June 10

The House of Delegates met at 9:30 a. m. and was called to order by the Speaker.

The Secretary read the minutes of the previous meeting.

Dr. M. L. Harris, Illinois, moved that the minutes be approved as read.

Seconded and carried.

Supplementary Report from Committee on Credentials

Dr. C. P. Meriwether, Arkansas, Chairman, presented a supplementary report from the Committee on Credentials, stating that 119 delegates had registered, all of whom were entitled to be and were seated in the House.

It was moved and seconded that the report be approved. Carried.

Report of Committee on Sections and Section Work

Dr. George D. Head, Minnesota, Chairman, presented the report of the Reference Committee on Sections and Section Work, as follows:

Your Committee on Sections and Section Work, to which was referred the report of the Council on Scientific Assembly, submits its report as follows:

First, the action of the Council on Scientific Assembly, separating the division of section work into two groups, one group to meet in the morning hours and the other group to meet in the afternoon hours, is approved. This committee recommends to the House of Delegates that the Council on Scientific Assembly be authorized to continue a further trial of this plan at the next annual meeting of the Association.

Second, your committee approves of the recommendation of the Council on Scientific Assembly, limiting the number of papers including addresses on the program of any one section to twenty-five, and recommends to the House of Delegates the rereferring of the amendments suggested by the Council in order to make this change effective to the Committee on Amendments to the Constitution and By-Laws for proper action and report.

George Douglas Head, Chairman,
S. R. Roberts,
J. B. Blake,
L. S. McMurtry,
John Ridlon.

This report was considered in two separate sections as presented, and on two separate motions, which were duly seconded and carried, the report was adopted, and Part 2 was referred to the Reference Committee on Amendments to the Constitution and By-Laws.

Report of Reference Committee on Medical Education

Dr. J. H. J. Upham, Ohio, Chairman, read the report of the Reference Committee on Medical Education, as follows:

Your committee, having carefully considered the reports of the Council on Medical Education, is especially impressed by the continuous progress made under the auspices of the American Medical Association and its efficient Council. The chief factors contributing to this result, it appears to your committee, are the surveys made by the Council, the publicity given to the results of the surveys, and the annual conferences held with representatives of the medical schools, state medical examiners and other agencies interested in medical education.

Your committee would recommend that the council be instructed to urge state boards of medical examiners to utilize to a greater extent the information gathered each year by the Association with reference to the student body. It would seem that an arrangement might be effected which would avoid the multiplicity of reports now enacted from the medical schools.

The attention of the members of the House of Delegates should be especially called to the facts set forth in Table 5, included in this council's report. This table shows that in some of the states the public is not safeguarded from poorly trained doctors. Attention is called particularly to the footnotes where appear the figures for Arkansas, California, Colorado, Missouri and Texas, in which large numbers of graduates of Class C medical colleges have been licensed either by examination or by reciprocity. It is evident from the facts set forth in this table that we are still far from an ideal situation in regard to medical education and licensure in the United States.

The committee endorses the program of the Council with reference to (*a*) medical education and licensure; (*b*) preliminary medical education; (*c*) reinspection of the medical colleges; (*d*) hospital survey, and (*e*) the study of facilities for postgraduate education. In connection with the latter, it is the opinion of your committee that many more hospitals can, with advantage, and will, become teaching institutions.

Finally, the committee recommends the adoption of the report as a whole and urges that the Association lend every encouragement to the Council in the furtherance of its work.

Respectfully submitted,

J. H. J. Upham, Chairman,
J. R. Phelps,
Franklin E. Murphy,
George David Stewart.

After reading the report, Dr. Upham moved its adoption. Seconded and carried.

Report of Reference Committee on Legislation and Political Action

Dr. Thomas S. Cullen, Maryland, Chairman, presented the report of the Reference Committee on Legislation and Political Action as follows:

Your committee listened with the greatest interest to the "Report of the Social Insurance Committee," as given by our incoming president, Dr. Alexander Lambert. The House has not the slightest conception of the amount of work this committee has accomplished. To have read the report in full would have taken at least an hour and a half. We would respectfully recommend that every member of the Association read this report in full.

Dr. Lambert has already told the House of Delegates that the subject under consideration is a stupendous one, and that it must be considered from every angle. Our committee recommends that the report of the Social Insurance Committee be adopted in toto and that the thanks of the House be extended to Dr. Lambert and his committee for the tremendous work they have already done and are doing to solve this problem, which vitally interests every man, woman and child in the United States.

Our committee heartily commends Dr. Lambert's committee in their refraining to make any definite recommendations on the subject at this time.

Your committee would suggest a change in the By-Laws whereby the title of this Reference Committee on Legislation and Political Action be changed to Reference Committee on Legislation and Public Relations.

This change is deemed advisable at this time, as the term political action has in some quarters been thought to refer to politics. In the words of Confucius, "Avoid the very appearance of evil. Do not stoop to tie your shoes in your neighbor's melon patch."

Thomas S. Cullen, Chairman,
Clarence Pierson,
Charles E. Humiston,

Dr. Cullen moved the adoption of the first part of the report. Seconded and carried.

The second paragraph of the report was read when Dr. E. Eliot Harris, New York, moved to amend by inserting the words "A special narcotic drug committee in conjunction with the Council on Health and Public Instruction shall be directed to study the entire narcotic drug situation."

The amendment was seconded and accepted.

It was moved that this part of the report as amended be adopted.

Seconded and carried.

Dr. Cullen read the third part of the report, and moved its adoption, and that the part referring to a change in the By-Laws be referred to the Reference Committee on Amendments to the Constitution and By-Laws.

Seconded and carried.

Report of Reference Committee on Amendments to Constitution and By-Laws

Dr. Floyd M. Crandall, New York, Chairman, read the report of the Reference Committee on Amendments to the Constitution and By-Laws, as follows:

Your committee respectfully reports as follows:

The Judicial Council in their report to the House of Delegates presented numerous amendments to the Constitution.

Your committee recommends that the amendments be laid over until the next annual meeting of the House of Delegates, as required by the By-Laws, and also recommends that the members of the House of Delegates be requested to study the changes proposed and send suggestions to the Secretary of the Judicial Council, to the end that after a year of deliberation, comprehensive and wise action may be taken in the changes proposed.

The Council on Scientific Assembly recommended that Section 12, Chapter XI, of the By-Laws be amended by striking out the word "thirty" and substituting the word "twenty-five."

The section will then read: The number of papers including addresses, on the program of any section shall not exceed twenty-five.

The committee recommends the adoption of this amendment.

The same Council also proposed an amendment to Section 1, Chapter XI, Item 13, of the By-Laws, by deleting the words: "13, Genito-Urinary Diseases" and substituting therefore the words "13, Urology."

The committee recommends the adoption of this amendment.

The Secretary in his report recommended amendment to the By-Laws, Section 5, Chapter IV, which reads: "Not more than three Honorary Fellows shall be elected in any one year" so that the section shall read "Not more than three Honorary Fellows shall be elected at any annual session; provided, however, that on recommendation of the Council on Scientific Assembly and by unanimous vote, the House may elect more than three Honorary Fellows."

The committee recommends the adoption of this amendment.

Dr. E. Eliot Harris of New York presented the following amendment.

To amend Chapter IV, Section 2, of the By-Laws by adding at the end of the section, "provided, however, when there is only one nominee for the office, a majority vote without ballot shall elect."

FLOYD M. CRANDALL, Chairman,
P. W. TOMLINSON,
JOSEPH M. AIKIN,
I. C. CHASE,
FRANCIS A. WINTER.

The report was considered section by section, and on several motions, which were duly seconded and carried, each section was adopted after which the report, as a whole, was adopted.

Dr. Floyd M. Crandall, New York, moved that the Secretary be empowered to arrange the amendments adopted so as to bring them into proper relation with one another and to make the Constitution and By-Laws consistent and to renumber any sections that may be necessary and prepare them for printing.

Seconded and carried.

Report of Reference Committee on Reports of Officers

Dr. Hugh T. Patrick, Illinois, Chairman, read the report of the Reference Committee on Reports of Officers, as follows:

To the House of Delegates:

Your Reference Committee on Reports of Officers begs to continue its report as follows:

First, with reference to the address of the Chairman of the House of Delegates, your committee recommends:

1. That the Council on Health and Public Instruction be instructed to make an earnest effort actively to cooperate with the National Educational Association in the matter of physical education and physical development of the children and youth of the Nation.

2. That the House of Delegates endorse the plan of an annual midwinter conference of the secretaries of the various sections of the Scientific Assembly.

3. That the House of Delegates endorse the plan of an annual midwinter conference of the secretaries of all the state societies with the officers of the American Medical Association, and that the Trustees and Secretary of the American Medical Association be requested to secure, if possible, the active cooperation of the state societies in this movement.

4. That the House of Delegates consider the wisdom of designating a time when it shall sit as a committee of the whole for the consideration of any subjects the delegates may wish to present, which subjects could not be presented in the regular routine procedures of the House.

This suggestion is made by your committee because in the past delegates have complained that they were unable to get before the House matters in which they were interested.

Second, with reference to the address of the President, your committee:

1. Would express the opinion that his first suggestion is covered by your committee's recommendation of a mid-winter conference of state secretaries; and his sound advice on hospital standardization has been covered by the decision of the House to create a Council or Bureau on Hospitals.

2. Earnestly recommends that the Council on Medical Education be instructed actively to interest itself in the subject of postgraduate medical education and to report at the next annual session the results of its investigations and such recommendations as it has been able to mature.

3. Recommends that the House make a formal endorsement of the work of the Council on Pharmacy and Chemistry and that the House endorse the suggestion of the President and that this Council make an effort to confer with and secure the cooperation of the reputable drug and pharmaceutical interests of the country.

4. Recommends that the Trustees be requested further to consider the feasibility of publishing a journal of surgery, and also a journal of health and medicine for lay readers, and that the House express itself as sympathetic to both ventures if the Trustees find them to be practicable.

5. Recommends that the House endorse the suggestion that each of the councils of the Association make an effort to get in touch with and coordinate their work with similar bodies or committees in the different states, with a view to mutual assistance and advantage.

Third, your committee recommends:

1. Commendation by the House of that portion of the report of the Judicial Council relating to old age and disability insurance for physicians.

2. That the Judicial Council be requested to continue its investigations of this subject and to present a plan for such insurance when it believes that a practicable one can be formulated.

Fourth, your committee recommends that the resolution presented by the House of Delegates of the Medical and Chirurgical Faculty of the State of Maryland relating to abbreviation of premedical education be referred to the Council on Medical Education.

Respectfully submitted,

HUGH T. PATRICK, Chairman,
ROCK SLEYSTER,
J. N. HALL,
EDGAR A. HINES,
J. E. LANE.

At this juncture, the Vice Speaker took the Chair.

The report was considered section by section. The three sections of the first division were read, and on three separate motions, which were duly seconded, were adopted.

Section 4 of the first division was read, and Dr. Patrick moved its adoption, which motion was seconded by Dr. C. E. Cantrell, Texas.

After discussion by Dr. Frederic E. Sondern, New York, Dr. John D. McLean, Pennsylvania; Dr. C. E. Cantrell, Texas, and Dr. E. Eliot Harris, New York, the motion to adopt this section was put and declared lost.

Sections 1, 2, 3, 4 and 5 of the second division of the report were read, and on five separate motions, which were duly seconded, were adopted.

Sections 1 and 2 of the third division were read, and on two separate motions, which were duly seconded, were adopted.

The fourth division of the report was read, and Dr. Patrick moved its adoption.

Seconded and carried.

Dr. C. E. Cantrell, Texas, then moved that the report of the committee as amended be adopted as a whole.

Seconded and carried.

Report of Reference Committee on Miscellaneous Business

Dr. Southgate Leigh, Virginia, presented the report of the Reference Committee on Miscellaneous Business and moved its adoption, which motion was duly seconded and carried.

The report is as follows:

The Reference Committee on Miscellaneous Business submit the following report: We are in hearty accord with the resolution introduced by Dr. H. M. Brown of Wisconsin, the purpose of which is the saving to the medical profession of the valuable works on medicine and surgery compiled by the Surgeon-General's Department, for the use of Army and Navy Surgeons, during the war, and which under existing conditions are likely to be destroyed. We therefore recommend that the Board of Trustees take such steps as are necessary to accomplish, if possible, this purpose.

Southgate Leigh, Acting Chairman,
H. B. Gibby, Secretary.

Dr. Hugh T. Patrick, Illinois, Chairman, stated that the Reference Committee on Reports of Officers had made no report on the Board of Trustees, which was referred to the committee. He moved that the report of the Board of Trustees be adopted and filed.

Seconded and carried.

Dr. A. N. Sinclair, Hawaii, moved that where the word "state" occurs in speaking of constituent associations, the words "state and territorial" be substituted. Motion seconded and referred to the Reference Committee on Amendments to the Constitution and By-Laws.

Dr. J. H. J. Upham, Ohio, presented the following resolution which was referred to the Reference Committee on Legislation and Political Action:

Whereas, There has been introduced in the Senate of the United States and referred to the Committee on the Judiciary, a Bill, S. 1258, "To prohibit experiments upon living dogs in the District of Columbia or in any of the Territorial or Insular Possessions of the United States, and providing a penalty for violation thereof," and,

Whereas, The passage of such a bill would seriously embarrass the scientific researches of the government in disease prevention and therapy, because of the fact that the dog is an essential laboratory animal in the prosecution of such researches, therefore be it

Resolved, That the American Medical Association vigorously protest against the passage of such legislation, which would be inimical to the proper conduct of essential and life saving researches of disease, and that a copy of this resolution be sent to the chairman of the Judiciary Committee of the Senate.

Dr. Frederic E. Sondern, New York, offered a resolution protesting against the repeal of the daylight saving act, which was referred to the Reference Committee on Hygiene and Public Health.

Dr. R. G. Stroud, Arizona, offered the following resolution, which was adopted unanimously by a rising vote:

To the members of the House of Delegates:

Whereas, The medical profession responded to the cause of the great war during the past two years and

Whereas, Many of our members who so responded have given their lives in this cause, be it

Resolved, That in the minutes of this body the following memorium be adopted:

IN MEMORIAM

To the soldiers of peace who have given their lives so nobly in the service of the great war. May their death be an everlasting memorial that the medical profession may strive to copy the wonderful spirit which called these men to the service of their country in time of need.

Dr. J. E. Lane, Connecticut, moved that if any business shall come from the sections between now and Thursday, the Secretary is empowered to refer the same to the proper Reference Committees for consideration and report to the House of Delegates on Thursday afternoon.

Seconded and carried.

Dr. C. Van Zwalenburg, California, presented the following resolution, which was referred to the Reference Committee on Medical Education:

Whereas, The practice of medicine involves such an enormous range of scientific study that many minds must of necessity cover different fields of it, and

Whereas, We recognize the difficulties involved in the time and expense needed to secure a degree to practice medicine under the present curriculum, and

Whereas, There is a popular demand for less highly trained physicians as evidenced by the multiplicity of faddists and quacks preying on the public, and

Whereas, Nine-tenths of the ailments for which a physician is called do not require the attention of an expert, now therefore be it

Resolved, 1. That the House of Delegates of the American Medical Association encourage the designation of the practice of general medicine or "family physician" as a distinct and dignified specialty.

2. That we ask the Council on Medical Education to consider the possibility of establishing a distinct curriculum leading to the degree for the practice of this specialty which shall materially shorten the course.

3. That we emphasize the need of specialization, consultation and reference of patients.

Dr. William C. Fisher, New York, Delegate from the Section on Stomatology, asked for a decision by the Chair as to whether the adoption of the resolution referring to the election of officers of the various sections took effect this year.

The Vice Speaker ruled that the amendment to the By-Laws which changed the time for the election of section officers takes effect this year.

On motion, the House of Delegates adjourned until Thursday afternoon, June 12.

Fourth Meeting—Thursday Afternoon, June 12

The House of Delegates met at 2 p. m. and was called to order by the Speaker.

Supplementary Report of Committee on Credentials

Dr. C. P. Meriwether, Arkansas, Chairman, presented a supplementary report of the Committee on Credentials, stating that there were two regularly elected delegates from the state of Pennsylvania, who were not present; that Dr. W. D. Martin as an accredited and duly elected alternate was present, and the Committee on Credentials moved that he be seated as a delegate from Pennsylvania. From New Mexico, both the delegate and alternate were not present; that Dr. D. D. Swearingin had credentials from Dr. Miller, the accredited delegate. The committee was unable to make a report regarding this matter and desired to leave it to the House of Delegates.

It was moved and seconded that Dr. Martin, from Pennsylvania, and Dr. Swearingin from New Mexico be seated as delegates.

Seconded and carried.

Dr. F. S. Simpson, the duly accredited delegate from the Section on Obstetrics, Gynecology and Abdominal Surgery, being absent, Dr. Reuben Peterson, Michigan, was selected by the section to take the place of Dr. Simpson. The Committee on Credentials recommended that Dr. Peterson be seated in the place of Dr. Simpson.

It was moved and seconded that the recommendation of the Committee on Credentials be concurred in.

Seconded and carried.

It was moved that the report of the Committee on Credentials be adopted.

Seconded and carried.

The Secretary called the roll, and 114 delegates responded.

At the conclusion of the roll call, Dr. C. P. Meriwether, Arkansas, Chairman, presented a supplementary report for the committee on Credentials, stating that there were three duly accredited delegates from Illinois, who were not present, and recommended that Dr. William Allen Pusey be seated as delegate.

Dr. Randolph Winslow, Maryland, moved that Dr. Pusey be seated. Seconded.

Dr. Arthur T. McCormack, Kentucky, made the point of order that the Constitution and By-Laws of the American Medical Association provided for a method by which delegates and alternates should be accredited; that there was no provision for such an appointment as this, and that therefore the motion of Dr. Winslow was out of order.

The Speaker sustained the point of order raised by Dr. McCormack.

The Secretary read the minutes of the previous meeting, which were approved.

Election of Officers

The next order of business being the election of officers, Dr. Floyd M. Crandall, New York, nominated Dr. Hubert Work, Pueblo, Colo, for President of the Association.

The Speaker: A nomination needs no second. The question of whether the Speaker of the House of Delegates is a member of the House or not has never been determined. That carries with it the question if whether or not the Speaker of the House is eligible to election for President of this Association. The question is a vital one and is likely to come up, after a president is selected, along down through the list of officers as to whether or not the Speaker of the House is qualified to cast a vote in case of a tie. That is a question I will not rule on. If it pertains to me personally, I would do it with my usual promptness, and all of you can understand what that ruling would be. This question should be determined. I will therefore ask the Vice Speaker to take the chair and request him to lay the question before the House of Delegates in its entirety and ask the members of the House to settle for all time the status of the Speaker of the House of Delegates, so far as his eligibility for office is concerned and his qualifications to decide tie votes and other incidental matters.

The Vice Speaker took the chair.

Dr. E. Eliot Harris, New York, spoke on the question of the eligibility of the Speaker of the House as a candidate for President of the Association, stating that he had read the Constitution and By-Laws very carefully, in addition to Roberts' Rule of Order, which, according to the By-Laws, governs the deliberations of this body, and he was unable to find that the Speaker of the House was a member of the House, and there was nothing either in the Constitution or By-Laws which prohibited the Speaker from being placed in nomination for President.

Dr. Floyd M. Crandall, New York, said he also had read very carefully the Constitution and By-Laws and there was nothing which prevented the Speaker of the House from being voted on for the presidency of the American Medical Association. Accordingly, Dr. Crandall moved that the Speaker of the House of Delegates be declared eligible to the office of president or to any other of the great offices.

Motion seconded by Dr. C. E. Cantrell, Texas.

The Vice Speaker: How shall this question be determined?

Dr. E. Eliot Harris, New York, moved that the question be determined by a rising vote.

Seconded and carried.

The Vice Speaker: The House of Delegates will now vote on the eligibility of the Speaker of this House to the office of president or for any other office.

A rising vote was then taken, with the result that sixty-nine delegates favored the eligibility of the speaker to the office of president or for any other office, and twenty were opposed.

The motion was declared carried.

Commandant Joseph R. Phelps, U. S. Navy, nominated Admiral William C. Braisted, of the U. S. Navy, for President of the Association.

The nomination was seconded by Dr. Randolph Winslow, Maryland; Dr. R. M. Funkhauser, Missouri; Dr. J. G. Brook, Michigan; Dr. John D. McLean, Pennsylvania, and Gen. F. A. Winter, of the U. S. Army.

Dr. Hubert Work: Mr. Vice Speaker: All my friends knew all along that I was not even a tentative candidate for President of the Association at this time. I felt it was very important that this question I raised in the beginning should be settled, not because of this alone, but for the reasons I gave. I have not been at any time a tentative candidate for the presidency of this Association, and I am not now. Will you pardon me if I take the privilege of withdrawing my name as a candidate for President of this Association and second the nomination of Admiral Braisted. (Loud applause.)

Dr. E. Eliot Harris, New York, moved that nominations be closed.

Seconded and carried.

Dr. E. Eliot Harris, New York, moved that the House of Delegates cast its vote by rising.

Seconded and carried.

The House did so, and Admiral Braisted was declared unanimously elected President of the Association.

The other officers elected are as follows:

First Vice President—Dr. David L. Edsall, Boston.

Second Vice President—Dr. Emery Marvel, Atlantic City, N. J.

Third Vice President—Dr. Eugene S. Talbot, Chicago.

Fourth Vice President—Dr. George H. Kress, Los Angeles.

Secretary—Dr. Alexander R. Craig, Chicago.

Treasurer—Dr. William Allen Pusey, Chicago.

Speaker of the House of Delegates—Dr. Hubert Work, Pueblo, Colo.

Vice Speaker of the House of Delegates—Dr. Dwight H. Murray, Syracuse, N. Y.

Trustees—Dr. A. R. Mitchell, Lincoln, Neb.; Dr. Oscar Dowling, Shreveport, La.; Dr. D. Chester Brown, Danbury, Conn.

President Lambert nominated the following as members of standing committees, and the House of Delegates confirmed the nominations:

Judicial Council—Dr. M. L. Harris, Chicago, and Dr. I. C. Chase, Fort Worth, Texas, to fill the unexpired term.

Council on Health and Public Instruction—Dr. Haven Emerson, New York, and Dr. Victor C. Vaughan, Ann Arbor, Mich., to fill the unexpired term.

Council on Medical Education—Dr. Isadore Dyer, New Orleans, and Dr. Arthur Dean Bevan, Chicago, to fulfil the unexpired term.

Scientific Assembly—Dr. J. D. Blake, Boston.

Supplementary Report of Council on Scientific Assembly

The Secretary presented a supplementary report from the Council on Scientific Assembly to which was attached the following list of delegates representing the medical professions of foreign countries and foreign guests:

The Council on Scientific Assembly recommends that this year at this Victory Meeting the House of Delegates shall elect to Honorary Fellowship those physicians who are in attendance at this annual session as delegates representing the medical profession of the several countries which were the allies of the United States in the prosecution of the world's war and also those other guests of the association from other foreign nations. The Council reports that several of the sections have nominated the foreign delegates and guests whose name appear on the appended list.

J. Shelton Horsley,
George H. Simmons,
Alexander R. Craig.

Gen. L. Melis, Delegate	Belgium
Col. Antoine Depage, Delegate	Belgium
Lieut.-Col. P. Nolf, Delegate	Belgium
Prof. Jules Duesberg, Delegate	Belgium

Capt. Vande Velde, Guest	Belgium
Dr. René Sand, Delegate	Belgium
Sir Arthur Newsholme, Guest	England
Major Ernest W. Hey Groves, Delegate	England
Sir St. Clair Thomson, Delegate	England
Lieut.-Col. Sir Shirley Murphy, Delegate	England
Sir Arbuthnot Lane, Delegate	England
Rear-Admiral Edgar R. Dimsey, Delegate	England
Dr. Frank Atcherley Rose, Delegate	England
Dr. Arthur F. Hurst, Delegate	England
Major Fernand LeMaitre, Delegate	France
Major Paul Bégouin, Delegate	France
Major Robert Picqué, Delegate	France
Major S. T. Lee, Delegate	China
Commander Chang Ting-han, Delegate	China
Dr. Asajiro Kamimura, Delegate	Japan
Dr. Senichi Uchino, Delegate	Japan
Dr. Ryuyo Kodama, Guest	Japan
Dr. Juan Guiteras, Delegate	Cuba
Dr. Emilio Martinez, Delegate	Cuba
Dr. Julio Carrera, Delegate	Cuba
Dr. Francisco Fernandez, Guest	Cuba
Dr. Peter F. Holst, Guest	Norway
Dr. Sven Ingvar, Guest	Sweden

Greece was represented by the following Fellows of the Association: Dr. John Constas and Dr. Alexander Alexion.

On motion, duly seconded and carried, the report was adopted.

Supplementary Report of the Judicial Council

Dr. M. L. Harris, Illinois, Chairman of the Judicial Council, submitted the following supplementary report from the Judicial Council:

There has been submitted to the Judicial Council the application for Associate Fellowship of the following physicians who are residents of Canada and who are each of them members of the chartered national medical societies of Canada and their respective provinces: Joseph Boulanger, Edmonton, Canada; L. Seale Holmes, London, Ontario, Canada, and W. O. Taylor, Cobalt, Ontario, Canada.

Each of these applications is approved by the Judicial Council.

M. L. Harris, Chairman,
H. A. Black,
Randolph Winslow,
William S. Thayer.

On motion, duly seconded and carried, the report was accepted.

Applications for Associate Fellowship

The Secretary then submitted applications for Associate Fellowship approved by the officers of the several sections.

On motion, duly seconded and carried, those nominated for Honorary Fellowship were elected, and the Secretary was instructed to officially inform all those recommended for Associate Fellowship who are not eligible for membership in the state or territorial association within whose jurisdiction they reside, and against whom no objection is filed by the officers of the constituent association having jurisdiction, that they are Associate Fellows of this Association.

Supplementary Report of Reference Committee on Legislation and Political Action

Dr. Thomas S. Cullen, Maryland, Chairman, presented the following supplementary report of the Reference Committee on Legislation and Political Action:

In regard to House Bill 5123 and Senate Bill 1189 to prevent transmission through the mails of advertisements relating to the treatment of venereal diseases and certain sexual disorders, your committee heartily recommends that the resolution asking that these bills be passed be acted on favorably by the House of Delegates.

Your committee recommends that the resolution of Dr. E. Eliot Harris, which is as follows:

> *Resolved,* That the Council on Health and Public Instruction, in cooperation with the special committee on narcotic drugs constituted at this annual session of this House, be directed to study the entire narcotic drug situation, economic and medical, in the United States and report to the House of Delegates at the next meeting,

be adopted by this House.

In relation to the resolution offered by Dr. J. H. J. Upham, Ohio, on Senate Bill 1258 concerning animal experimentation, your committee recommends the adoption of this resolution by the House of Delegates, and that the matter be referred to the Council on Health and Public Instruction for appropriate action.

Your Committee received the following preambles and resolutions from the Section on Pharmacology and Therapeutics. Your Committee recommends that these also be referred to the Council on Health and Public Instructions:

PREAMBLES AND RESOLUTIONS PASSED BY THE SECTION ON PHARMACOLOGY AND THERAPEUTICS

> Whereas, The medical procedures of the recent war which are in most cases the direct result of experimentation on animals have led to the saving of hundreds of thousands of our soldiers from sickness and death, and
>
> Whereas, Further progress along these lines is menaced by a bill now before Congress known as No. S. 1258 prohibiting the use of dogs for experimental purposes, be it
>
> *Resolved,* That it is the sense of the Section of Pharmacology and Therapeutics of the American Medical Association that this proposed legislation is unwise, that it is a detriment to the progress of medicine and surgery, and that it imperils the health and lives of the citizens of the United States; and be it further
>
> *Resolved,* That the Section on Pharmacology and Therapeutics of this association urges on the Congress that this bill should not become a law.

Your committee has carefully considered the resolution adopted by the House of Delegates of the Medical Society of the State of New York which resolution is as follows:

> *Resolved,* That the delegates of the Medical Society of the State of New York to the American Medical Association be and are hereby instructed to introduce a resolution in the House of Delegates of the American Medical Association opposing the scheme of compulsory health insurance and to support it in every way possible.

At the meeting of the House of Delegates of the American Medical Association held on Tuesday last, your committee commented on the splendid work the Committee on Social Insurance had done and recommended that they be thanked for the tremendous amount of work they had already accomplished and further recommended that they be commended for having made no special recommendations at this time. We further advised that the report of the committee be adopted in toto. This the House of Delegates adopted unanimously.

To comply with the resolution from the state of New York would be an attempt to settle the subject when the evidence for and against is far from complete. Any further action of this body at this time would be a reversal of the action unanimously taken on Tuesday. We recommend that this resolution be tabled.

Clarence Pierson,
C. W. Stahl,
Charles E. Humiston,
Thomas S. Cullen, Chairman.

The report was considered section by section, and on several motions, duly seconded and carried, the report was adopted.

Dr. J. W. Schereschewsky, District of Columbia, moved that the report be adopted as a whole.

Seconded and carried.

Supplementary Report of Reference Committee on Sections and Section Work

Dr. George D. Head, Minnesota, Chairman, presented a supplementary report of the Reference Committee on Sections and Section Work.

The report follows:

> No Fellow shall contribute or read before his section or any section of this Association more than one paper in two successive years, except by special invitation adopted by a formal vote of the section.

Submitted for the Reference Committee.

George D. Head, Chairman.

Continuing, the chairman of this reference committee stated that in accordance with the understanding of the reference committee the recommendation submitted involved a change in the By-Laws or in the standing rules, and consequently it should lie over until the 1920 annual session. He therefore moved that the report be received in order that it shall be submitted to the House of Delegates at the next annual session for action.

Dr. Arthur T. McCormack, Kentucky, arose to a question of parliamentary inquiry and asked the Speaker to rule on whether or not this recommendation of the Reference Committee might not be adopted at this meeting as a standing rule of the association.

The Speaker ruled that the suggested procedure would be in order.

Thereupon Dr. McCormack moved to amend the recommendation of the reference committee by substituting the following:

> *Resolved,* That the House of Delegates shall establish a standing rule to the effect that no Fellow shall contribute or read before his section or any section of this association more than one paper in two successive years except by special invitation adopted by a formal vote of the section.

Dr. Head, Chairman of the Reference Committee, and mover of the motion, together with the seconder, accepted Dr. McCormack's amendment.

After discussion by Dr. Hugh T. Patrick, Illinois; Dr. M. L. Harris, Illinois, and Dr. J. B. Blake, Massachusetts, Dr. Harris moved that the resolution be laid on the table.

Seconded and carried.

Report of Reference Committee on Rules and Order of Business

Dr. Joseph Rilus Eastman, Indiana, Chairman of the Reference Committee on Rules and Order of Business, presented the following report:

The Reference Committee on Rules and Order of Business recommends for adoption the resolution offered by Dr. M. L. Harris of Illinois, as follows:

> *Resolved,* That the Secretary be instructed to have published in the handbook as an addendum all resolutions that express an opinion or policy of the Association that have been adopted by the House of Delegates during the past five years, and that this addendum be added to from year to year as new resolutions are adopted so that the members of the House may know what opinion and policies have been approved by this body, with the suggestion that the period embraced in the review be lengthened from five to ten years.

J. RILUS EASTMAN, Chairman,
G. WYTHE COOK,
JOSEPH R. MORRELL,
F. LEM. HUPP.

Dr. C. E. Cantrell, Texas, moved that the report be adopted as read. Seconded.

After discussion by Dr. V. G. Vecki, California; Dr. E. Eliot Harris, New York; Dr. C. E. Cantrell, Texas, and Dr. R. G. Stroud, Arizona, the motion to adopt was put and carried.

Report of Reference Committee on Hygiene and Public Health

Dr. J. W. Schereschewsky, United States Public Health Service, Chairman, presented the report of the Reference Committee on Hygiene and Public Health, and moved its adoption.

The report is as follows:

Referring to the proposed repeal by Congress of the Daylight Saving Act, your committee begs to submit the following report in relation thereto:

The national experience with the Daylight Saving Act during the past two years has shown in the opinion of the committee that the action of this bill has been wholly beneficial, not only as it added to the total of national health by lengthened hours of recreation in the open air, but it is the belief of the committee that notable economic savings have been made in the use of fuel, thereby materially assisting the conservation of national resourses, which still is and always will be essential. Your committee therefore begs to report the following resolution with the recommendation that it be adopted by the House of Delegates, and that copies of this resolution be sent, respectively, to the Speaker of the House of Representatives and the President of the Senate. Resolved that:

> WHEREAS, The two years experience of the medical profession with the Daylight Saving Act has shown that this act has added materially to the sum total of national health and vigor by the increased recreational opportunities and encouragement of outdoor pursuits which it has afforded, and
>
> WHEREAS, Through the operation of this act, material savings have been effected in the use of fuel, and
>
> WHEREAS, Continued conservation of national resources still are and always will be essential to the prosperity of the nation, therefore be it
>
> *Resolved,* That the House of Delegates of the American Medical Association vigorously protest against the repeal of the Daylight Savings Act, and that the Secretary of the Association be instructed to send copies of this resolution to the Speaker of the House of Representatives and the President of the Senate of the United States.

J. W. SCHERESCHEWSKY, Chairman.
H. A. ROYSTER,
C. D. SELBY,
V. G. VECKI.

Dr. Arthur J. Bedell, New York, presented a resolution passed by the Section on Ophthalmology on the daylight saving law, and moved to amend, which motion was seconded, that copies of the report just presented be sent to each senator and representative and also to the Speaker of the House of Representatives.

The amendment was accepted, and the original motion as amended was put to a vote and carried.

Supplementary Report of Reference Committee on Amendments to the Constitution and By-Laws

Dr. Floyd M. Crandall, New York, Chairman, presented a supplementary report from the Reference Committee on Amendments to the Constitution and By-Laws, as follows:

1. In reference to changing the name of the Reference Committee on Legislation and Political Action to Legislation and Public Relations, your committee recommends its adoption.

2. Regarding the resolution introduced by Dr. A. N. Sinclair, Hawaii, substituting the words "state and territorial" wherever the word "state" occurs, the committee recommends that wherever practical, when constituent associations are spoken of in correspondence or in articles, the fact that these constituent asssociations are both state and territorial shall be recognized.

3. The following resolution was adopted at a business session of the Section on Dermatology and referred to your Reference Committee:

> *Resolved,* That the House of Delegates of the American Medical Association be petitioned to amend the title of the Section on Dermatology by adding to its present title the words "and Syphilis."

The committee recommends that this section be amended as set forth in the resolution, and that the amendment lie over until next year.

Submitted for the Reference Committee.

FLOYD M. CRANDALL, Chairman.

The report was considered section by section, and on three separate motions, duly seconded and carried, the report was adopted.

Supplementary Report of Reference Committee on Reports of Officers

Dr. Hugh T. Patrick, Illinois, Chairman, presented a supplementary report from the Reference Committee on Reports of Officers, as follows:

To the House of Delegates: Your Committee on Reports of Officers begs to report further as follows:

Concerning the report of the Secretary it recommends:

1. That the House of Delegates earnestly request national, state and county medical organizations to assume responsibility to returning discharged officers of the United States Army and Navy and urge these organizations to assist in every possible way such officers to reestablish themselves in civil life.

2. That the House of Delegates refer that part of the Secretary's report relating to a special authorized designation for Fellows of the Scientific Assembly to the Council on Scientific Assembly, with power to act.

Submitted for the Reference Committee.

HUGH T. PATRICK, Chairman.

At the conclusion of the report, Dr. Patrick moved its adoption, which motion was duly seconded and carried.

Supplementary Report of Reference Committee on Medical Education

Dr. J. H. J. Upham, Ohio, Chairman, presented a supplementary report from the Reference Committee on Medical Education, and moved its adoption, which motion was duly seconded and carried.

The report is as follows:

The Reference Committee on Medical Education has carefully reviewed the resolution presented by C. Van Zwalenburg concerning the designation of general practitioners as specialists, and the resolution presented by Dr. R. Winslow concerning the rearrangement of premedical education, and recommends the referring of both resolutions to the Council on Medical Education.

Respectfully submitted for the Reference Committee.

J. H. J. Upham, Chairman.

Supplementary Report of Board of Trustees

Dr. Thomas McDavitt, Minnesota, Chairman of the Board of Trustees, presented a supplementary report from the Board of Trustees, as follows:

The Board of Trustees took up the question of the next place of meeting several months ago and investigated the facilities which were available for the holding of an annual session of the Association in a number of the larger cities. The result of this investigation prompts the Board of Trustees to recommend that the 1920 annual session shall be held in New Orleans, La.

The board further recommends that the time for holding the annual session shall be referred to the board for its action. The board is of the opinion that the time for the next annual session should be in the latter part of April or the early part of May.

Thomas McDavitt, Chairman.

Dr. C. E. Cantrell, Texas, moved the adoption of the report. Seconded and carried.

An American Hospital and Postgraduate School of Medicine in London

The Speaker asked the House of Delegates whether it would receive a communication which had been submitted because it relates to a measure in which one of the delegates representing the medical profession of Great Britain is personally greatly interested. There being no objection, the following communication was read.

> It is with deep interest and gratification that the members of the American Medical Association learn of the project to establish and maintain in the city of London, England, an American hospital and postgraduate school, the school for physicians of America who desire to take advantage of the wealth of clinical material which London affords, and the hospital in part for American citizens who may become ill while abroad.
>
> The institution is to be built by American residents of London. The project which originated with Mr. Franklin, an American surgeon who is attached to the Middlesex Hospital in London, is largely in the hands of Mr. Newton Crane of the American Embassy, and of Mr. Van Duzer, who guarantee that ample funds will be provided for the purpose. The sum of £1,000,000 has been suggested.
>
> Lord Reading has been elected president, and has suggested a lay committee comprising all of the most prominent men in England. A corresponding list of prominent Americans is being selected. Hon. William H. Taft, Ex-President of the United States, has been approached in reference to his acceptance of the presidency on this side of the ocean.
>
> The medical contingent of the British committee consists of Sir Humphrey Robertson, Sir William Osler, Sir John Bland Sutton and Sir Arbuthnot Lane.
>
> It is proposed that the plan comprise three integral parts:
>
> 1. A private home or hospital for Americans abroad.
> 2. A nonpaying clinical portion of from 100 to 200 beds.
> 3. The major portion of the building to consist of a home for the American Medical Association. This will comprise lecture room, theater, library, laboratories, and all necessary equipment, and facilities for postgraduate study and research. The clinical and other materials which Great Britain affords for substudy and research will be at the disposal of American physicians who attend the school.
>
> Among the objects of the plan are the development of friendly competition in research in the field of the medical sciences, and the welding of the two English-speaking nations into one body.
>
> It is learned that it is the desire of the men in England that the American Medical Association should formulate concrete ideas for the development of this project, and that the Association cooperate with the British Committee in bringing about its consummation.
>
> Be it therefore,
>
> *Resolved,* That this matter be referred to the Council on Medical Education with instructions to report to the Board of Trustees some plan of effective cooperation of the American Medical Association with the British committee in charge of the American postgraduate medical school and hospital of London.

On motion, duly seconded and carried, the foregoing communication was referred to the Council on Medical Education.

Special Committee on Narcotic Drugs Appointed

The Speaker appointed as a special committee called for in a resolution offered at a previous meeting of the House on the question of narcotics, Dr. E. Eliot Harris, New York, Chairman; Dr. A. T. McCormack, Kentucky; Dr. Paul Waterman, Connecticut, and Dr. Alexander Lambert as member, ex officio.

Unfinished Business

Under the head "unfinished business," Dr. Reuben Peterson, Michigan, presented the following resolution, which was passed by the Section on Obstetrics, Gynecology and Abdominal Surgery:

> Whereas, An effort is being made to organize an International Congress of Obstetricians and Gynecologists at a meeting in Brussels during September next, at which American obstetricians and gynecologists will have representation, therefore, be it
>
> *Resolved,* That the Section on Obstetrics, Gynecology and Abdominal Surgery of the American Medical Association unanimously approves of this movement, stands ready to cooperate in every way, and cordially invites the Congress to hold its initial meeting in New York at a convenient date to be determined.

Dr. H. M. Brown, Wisconsin, moved that this resolution be received and referred to the Council on Scientific Assembly.

Seconded and carried.

Dr. William Van Valzah Hayes, New York, delegate from the Section on Gastro-Enterology and Proctology, presented the following resolution, which was referred to the Council on Medical Education:

> Whereas, Medical officers who served overseas state that many soldiers among the American Expeditionary Forces suffered from diseased conditions of the rectum, requiring operation in the war zone, which should have been recognized by proper examination at some time before their embarkation, and
>
> Whereas, Increased strain on transportation and hospitalization were induced thereby; be it
>
> *Resolved,* That in order to improve the effectiveness of preparedness for possible future emergencies we recommend that suitable instruction in modern methods of rectal examination be given to student medical officers, being trained for Army and Navy service, and to this end instruct our secretary to send a copy of this resolution and recommendation to the Surgeon-General of the Army and to the Surgeon-General of the Navy, for their consideration.

Dr. Arthur T. McCormack, Kentucky, requested unanimous consent to introduce a motion to reconsider the actio taken in adopting the report of the Reference Committee on Reports of Officers, which action was taken at the last meeting of the House.

He stated that his purpose in asking for the consideration of a motion to reconsider, is that an amendment may be made to the report by adding a recommendation that in the execution of the laws and regulations pertaining to child welfare and child education, the House shall recommend that these executive functions be exercised, when they are within the scope of the federal government, by the United States Public Health Service, and all questions falling within the jurisdiction of the states shall be exercised by the respective state departments or boards of health. Unanimous consent having been granted, Dr. McCormack introduced a motion to amend the report as stated above and to adopt the amended report, which was seconded.

After discussion by Dr. M. L. Harris, Illinois; Dr. J. W. Schereschewsky, District of Columbia, and Dr. Isaac A. Abt, Illinois, the report, as amended, was adopted.

Dr. E. Eliot Harris, New York, asked unanimous consent, which was granted, to bring a matter before the House, and requested the Vice Speaker to take the Chair.

The Vice Speaker took the Chair.

Dr. Harris then moved that the House of Delegates express its appreciation and good will to the Speaker by a rising vote.

Motion seconded and unanimously carried.

Dr. Arthur T. McCormack, Kentucky, moved that a rising vote of thanks be extended to the members of the Local Committee of Arrangements and to others who have contributed to the success of this Victory Meeting.

Seconded and carried.

As there was no further business to come before the meeting, the Speaker declared the House of Delegates adjourned sine die.

THE SCIENTIFIC ASSEMBLY

THE OPENING GENERAL MEETING

Tuesday Evening, June 10

The opening meeting of the Association was held in the Music Hall of the Steel Pier, and was called to order at 8:30 p. m. by the President, Dr. Arthur Dean Bevan, Chicago.

Music was rendered by the Philadelphia Navy Yard Band of twenty-three pieces.

A number of past presidents of the Association, members of the Board of Trustees, and foreign guests occupied seats on the stage.

Prayer was offered by Abner H. Lucas, Ph.D., D.D., Atlantic City.

President Bevan introduced Dr. Emery Marvel, Chairman of the Local Committee of Arrangements, who called attention to the list of entertainments provided for the members and guests.

Addresses of Welcome

Hon. Harry Bacharach, Mayor of Atlantic City, was introduced, and delivered the following address of welcome:

ADDRESS OF WELCOME BY MAYOR OF ATLANTIC CITY

Mr. President, Ladies and Gentlemen, and Distinguished Guests from Foreign Lands: I am sure you all know that it is a mere matter of form for me to welcome you to this great playground of ours and to this great convention city of America, because every one in this country surely must know that the American Medical Association is welcome, not only to Atlantic City but to any city in this great country of ours. The men and women of your profession, who so unselfishly and loyally performed their work not only in this country but also on foreign shores, and who, when the great epidemic of influenza struck this country, cared not for finances or even their own health, deserve great credit, because they were willing to sacrifice all that lives might be saved.

We, in Atlantic City, are proud of many things. We are proud of our magnificent boardwalk, five miles long and 100 feet wide, where half a million people promenade at one time, where you never see any one acting in an unbecoming manner, where women unaccompanied are not molested by any one. We are proud of our magnificent force of ninety life guards, who protect the lives of more than 5,000,000 people that bathe here in the summer season, without a single loss of life by drowning.

We are proud of our magnificent streets, which are better lighted, better paved and cleaner, we believe, than any other city in the United States. We are proud of our magnificent hotels, in which we feel you can get more for your money than in any other hotels in the country, where a person of the humblest means can come and enjoy himself along with the rich. But above all, my friends, in this great playground of ours, there has not been a call of our county for any loan or any drive in which Atlantic City failed to go over the top. From this city, more than 3,500 of the best young manhood responded to our country's call. (Applause.) When the war first broke out, we did not wait for Congress to act, but we organized a Liberty Club, so that everybody in this city from the humblest walks in life to the proprietors of our magnificent hotels became members. We took care of the dependents of our soldiers and sailors in a fitting manner. (Applause.)

While in this city we want all of you to make yourselves at home, and particularly our foreign guests. We want in this country nothing but 100 per cent. American citizens. We believe that the Bolshevik or any of his type who is not satisfied to fight and even die, if necessary, for Old Glory, should go back to the country from which he came, and not stay in this great and glorious country of ours. (Applause.)

This war has taught us one important thing: that there is no North, there is no South, there is no East nor West.

In behalf of the citizens of Atlantic City, I desire to present to you and through you, Mr. President, to this convention, our best wishes that your stay here will be a pleasant one; that it will be profitable and beneficial, not only to your profession but to the United States and to the world at large. So on behalf of its citizens, I want to present to you, not only the key to Atlantic City, but the key to the hearts of the people of this city. [Here the mayor handed the key to President Bevan.] (Applause.)

President Bevan said: In the name of the Association, we accept this welcome. If any of you lose your night key and this meeting adjourns very late, I will lend you this key, which will unlock any one of the thousand hotels in Atlantic City. I am now going to call on the president of the oldest state medical society in the Union. It is more than 150 years old. I take great pleasure in introducing to you Dr. Thomas Harvey, President of the Medical Society of the State of New Jersey.

ADDRESS OF WELCOME BY DR. HARVEY, PRESIDENT OF MEDICAL SOCIETY OF THE STATE OF NEW JERSEY

Mr. President, Fellows and Guests of the American Medical Association, Ladies and Gentlemen: It is my pleasant duty to represent the Medical Society of the State of New Jersey in welcoming the members of the American Medical Association to the shores of our compact little state; a welcome that is universal. From the wooded dells of Sussex to the shining sands of Cape May, nowhere in the world is there a convention city so well suited to your purpose; for whether you come for scientific instruction, or the improvement of your health, or just for the happiness of your souls, it is most fitting that our state society should join in this welcome, because, as has been said by President Bevan, we are the oldest medical society in the Union, and have a sort of grandmotherly interest in all societies, especially this, which is reaching its seventieth birthday. Moreover, this year, of all years, we should gather here at this Atlantic seashore and recall the fact that one year ago this shore was in the war zone and exposed to bombardment, and that now we have reached the piping times of peace when our minds are free from the horrors of impending invasion.

We also welcome the great army of medical men, over 35,000 strong, who sacrificed all that life might be made worth while and laid on the altar of their country their wealth of experience and knowledge, the result of many years of hard work, their love of home and family, their hopes for the future, and even life itself, that our army and navy should have everything that modern science has to offer for safeguarding and rehabilitation.

We also welcome the other great army of medical men who were compelled to remain at home, who gave much thought and labor and time to the work of selected service in the preliminary examination of our soldiers. There was no more wonderful demonstration of the prompt efficiency of our people in the whole course of the war.

We also welcome the medical men of our allies, who bore the burdens of the day, meeting the new problems in war time surgery, with such wonderful skill and devotion, so that when at last we entered the war, we found that the principles underlying the work had been so thoroughly worked out that our men had only to study and apply details.

We welcome also that devoted band of American physicians who from the outbreak of the war in 1914 rushed over to the assistance of their European brothers and aided much, as we know, in establishing the surgical treatment of wounds on a sound foundation.

We also welcome here those noble souls who, in the trenches and in No Man's Land, offered up the supreme sacrifice; and this spirit we feel sure is here in attendance at this VICTORY MEETING, watching to see if we are faithful to our trust and to carry on as they did in our divinely appointed office, carrying succor to those afflicted with disease.

We certainly can take great pride in the work that the doctors have done in this world war and in the great reduction of permanent casualties that they have effected.

We in New Jersey are also pround of the fact that one third of the membership of our state society volunteered in the service.

Our duty of the future is to enlarge and strengthen our organization in all its ramifications, so that we may be prepared for the tremendous social changes that are threatening the peace of all classes of society. If the doctors are to keep medicine as one of the liberal professions, we must antagonize all efforts to reduce it to a trade. But if it is to be a trade, we must organize as efficient a union as possible and use union methods for our protection. (Applause.)

President Bevan said: I regret exceedingly that I have to announce that the Honorable Walter E. Edge, governor of New Jersey, United States senator-elect, has been unavoidably detained and will not be here with us tonight.

REMARKS BY PRESIDENT BEVAN IN INTRODUCING SURGEON-GENERAL IRELAND

One year ago the American Medical Association held a great war meeting. It was a call to the medical profession to organize for war. We asked for the necessary medical officers for an army of 5,000,000 men or more and for a navy of a million men if it was needed. The call was answered promptly and magnificently by the organized medical profession of the country. Within six months from that time 50,000 medical men and women had offered their services to the government, and almost 40,000 had been accepted and received their commission. At that meeting few of us dreamed, none of us dared to hope, that within six months the brutal military power that had forced us into war would be broken and would be humbly suing for peace. (Applause.)

The war was won when America threw the weight of its unlimited resources and its hundred million people into the scales on the side of humanity. The war was won by the hundreds of thousands of men who volunteered and by the 23,000,000 who gladly and without protest answered the call of the draft to the colors. The war was won not by the professional military establishment but by the men who were called from civil life into military service and were rapidly trained and organized into a great and efficient military machine. When the war began, the medical department of the army consisted of less than 500 medical officers. When the war ended, the medical department consisted of 34,000 medical officers and 250,000 men and women. (Applause.) Ninety-eight per cent. of the personnel of the medical department were called from civil life. The small regular medical department furnished the leaven, but the great mass came from the civilian population. Ninety-eight per cent. of the work of the medical department was done by the civilian physicians and the Red Cross nurses and the boys from all walks of life who volunteered or were drafted into the medical service.

The war has been won, and we are assembled here at a great victory meeting of the organized medical profession of the country. We are here to pay tribute to the medical men and women who served their country in this war. We are here to pay a tribute to the men and women who died in the service of their country. In sorrow, and in gratitude that they served their country and humanity so well, we place a wreath of flowers on their grave.

We are here to pay tribute to the men and women who served and whose health was shattered in the service. We owe them a great debt—a debt that should be paid as far as it can be paid by a grateful country and a grateful profession.

We are here to pay a tribute to the men and women who are returning strong and well from military service abroad and the cantonments in this country, back to their homes and their civilian practice. We join with their families who with tears of joy have welcomed them home. They sacrificed much, but they come back to us broadened and strengthened. Their services have earned for them special recognition and the support from the communities in which they live and their colleagues. (Applause.)

We are here to pay a tribute to the regular medical officers of the army and navy for the efficient services which they rendered in training the thousands of medical men coming from civil life in the work of the military surgeon.

We are here to pay a tribute to Surgeon-General Gorgas (applause), to Surgeon-General Ireland, and to Surgeon-General Braisted for their able leadership. (Applause.) We are here to pay a tribute to the great teachers of medicine and surgery and hygiene and the medical and surgical specialties who at once volunteered and gave the government and the troops the benefit of their special knowledge and expert advice.

We are here to pay the greatest tribute to the rank and file of the medical men who served where they were placed without special rank or special distinction, for the work of these men outweighs and overshadows all the rest. (Applause.)

We are here to pay tribute to the 30,000 medical men who served on the draft boards and advisory boards. These men rendered valuable services to their country.

The war has been won. The great military force in khaki and in blue is fast fading back into civil life. The medical profession of the country can well be proud of the great part which it has played. To realize the magnitude of our effort it is but necessary to state that within a short time we developed a greater medical service than that of England, France, Belgium, Canada and Australia combined. (Applause.) Our best men entered the service. Our soldiers and sailors were given the best of medical care and surgical skill. In such an enormous task of creating within a short time a great and efficient medical service, there was necessarily some confusion, some friction, some oversights, some mistakes; but when one looks at the sum total of the accomplishment of the medical profession of America in this war, we are proud of both our profession and our country. (Applause.)

This meeting of the American Medical Association is a great victory meeting, and we have invited to it members of the medical professions of the countries which were our allies in the winning of the war, and which are now our allies in the peace we hope will make the world safe for democracy. We welcome them to America. We welcome them to this meeting of the American Medical Association. We extend to them our hand in friendship and in the fellowship of science.

These men come as the guests of the American Medical Association. They have served in the military service of their own countries. It is, therefore, eminently fitting and proper that they should be welcomed here by a representative of the medical services of our government. It is my great privilege, as President of the Association, to ask one who served his country with distinguished ability both on the battlefields of France and in organizing the medical department at Washington, to welcome our guests and introduce them to you. I have the honor to introduce Surgeon-General Ireland. (Applause.)

ROSTER OF INVITED GUESTS

Surgeon-General Ireland called the roster of invited foreign guests, and as the name of each was called, the introduction was acknowledged.

England was represented by Lieut.-Col. Sir Shirley Murphy, Sir William Arbuthnot Lane, Sir St. Clair Thomson, Sir Arthur Newsholme, Rear Admiral Edgar R. Dimsey, Dr. Ernest W. Hey Groves, Dr. Frank Atcherley Rose, Dr. Arthur F. Hurst and Mrs. Eleanor Barton.

France was represented by Major Fernand Lemaitre, Dr. P. Bégouin, Dr. Robert Picqué, Dr. Maurice Heitz-Boyer, and Dr. C. Mullon.

Belgium was represented by Gen. L. Melis, Col. Antoine Depage, Lieut.-Col. P. Nolf, Professor Duesberg, Captain Van de Velde and Dr. Réné Sands.

Greece was represented by Drs. John Constas, G. Gavaris, Constantine Caroussos and Alexander Alexion.

Japan was represented by Drs. Asajiro Kamimura, Senichi Uchino and Ryuzo Kodama.

China was represented by Drs. S. T. Lee, William Wesley Peter, Chang Ting-Han and Hsu Ming-Shoo.

India was represented by Belle J. Allen.

Cuba was represented by Drs. Juan Guiteras, Emilio Martinez, Julio Carrera and Francisco M. Fernandez.

Argentine was represented by Dr. Pedro Chutro.

Ecuador was represented by Dr. E. L. Kingman.

Peru was represented by Dr. Alejandro Acha.

Norway was represented by Dr. Peter F. Holst.

Sweden was represented by Dr. Israel Holmgren and Sven Ingvar.

ADDRESS OF SURGEON-GENERAL IRELAND

After introducing the foreign guests, Surgeon-General Ireland said:

Ladies and Gentlemen: Two years ago this evening an advanced party of the American Expeditionary Forces landed in France. From that day they received every possible assistance and courtesy from the medical departments of the allied armies. They had been in this war three years before we joined and had learned many things which we knew nothing about and could only learn by practical experience. The war, as you know, was carried on in the trenches, and this produced new elements in caring for the wounded and taking care of the sick. New methods had been developed in caring for the wounded at the casualty clearing stations and base hospitals. Great advances had been made in war surgery, which our surgeons were not familiar with. New methods had been developed of evacuating a great number of the sick and wounded to the base and home port medical departments of the allied armies Through the surgeons in Great Britain at their front area, we were made familiar with the new forms of warfare in the trenches, where our surgeons learned new lessons in war surgery and were made familiar with the underlying principles in the care of the wounded and in many modern ways of evacuating them to the base hospitals

We went to France when that country was greatly exhausted in man power and material, by months of cruel war. The problem of hospitalization to take care of the thousands of sick and wounded that were there was a tremendous one. We received the most cordial support from the medical departments of the allied armies in meeting this problem. They gave us many hospitals, which amounted to thousands of beds and assisted us in locating other hospitals. Not content with this, their surgeons came in great numbers to Paris for the purpose of attending the meetings of the Research Society, and they gave us freely of their newly acquired knowledge. In these ways and in many others, too numerous to mention, our associates in Europe assisted us with that sympathy and teamwork which should always characterize the medical profession.

Gentlemen, delegates and guests, it is a great pleasure to welcome you to this VICTORY MEETING of the American Medical Association, and a privilege, a rare privilege, to present you, as invited guests, to its members. (Applause.)

President Bevan said: My next duty is one that is very pleasing to me. The American Medical Association at its last meeting honored a man by electing him to the presidency of the Association; a man who stands for the best in American medicine. They honored him because he had done such splendid work in the organization itself. He had devoted years of his time and energy to elevating the standards of our professional work by putting his shoulder to the wheel in the machinery of the American Medical Association, and had accomplished a great deal of good. They honored him because he was one of the first men to answer the call and don the khaki-colored uniform of the medical department. The American Medical Association has honored many great and worthy men by electing them to the presidency of the Association. It has, however, never bestowed this honor more worthily on a man who deserves it more and who will fill the office with greater efficiency than Alexander Lambert, and I have the great pleasure of introducing him to you. (Applause.)

ADDRESS OF THE PRESIDENT, ALEXANDER LAMBERT

Before delivering his address as President of the American Medical Association, Dr. Lambert said:

Mr. President, Invited Foreign Guests, Ladies and Gentlemen: It is with keen pleasure that I desire to make my first official act as president of this Association an act of welcome to the members of the allied army, whom I had learned to know abroad, and I am indeed happy to be the one that thrice welcomes them here, and to add my welcome to the others that have already been extended.

It means new friendships and a new fellowship in medicine; it means the cementing of the fellowship and friendship that we found abroad when we went as strangers to a foreign land. It means more than any words can express, and the welcome that I bid you, gentlemen, is one which in its heartiness and in its sincerity is very deep indeed. It represents the friendship of the American Medical Association; it represents in turn the comity of the American Medical Association in the fellowship of medicine of its friends abroad. Thrice welcome are you, and welcome indeed. (Applause.)

President Lambert then delivered his address, which was published in THE JOURNAL, June 14, 1919, p. 1713.

THE VICTORY MEETING

Wednesday Evening, June 11

The VICTORY MEETING of the Association was held, June 11, with the President, Dr. Alexander Lambert, in the chair.

GENERAL F. A. WINTER, representing the U. S. Army, stated that during the war many able, large-minded, energetic and capable men had given up the possibilities of large lucrative practices to serve with the army, while others had adopted it as a life-time calling. Before the present war, but few knew anything about the medical conditions of the army. Now, with the backing and support that were formerly lacking, great improvement has resulted. The whole medical corps, supported by the American Medical Association and kindred organizations, deserves great credit for what has been accomplished.

COMMANDANT JAMES R. PHELPS, representing the U. S. Navy, said that the death rate of the navy for the first year of the war was lower than for the previous year of peace, and that the death rate for disease of the entire navy for the whole period of the war was so low that it reflected great credit on the medical profession of the United States and the medical corps of the navy, as well as on the Surgeon-General because of his able leadership. The death rate for the whole period of the war was 8.8, the lowest death rate that has ever been reached by the naval or military service of the United States at war.

Dr. C. C. Pierce, representing the U. S. Public Health Service, referred to the various activities of this service during the war and of how military needs caused a great increase in the manufacture of biologic remedies, such as serums, antitoxins and vaccines, all of which had to be tested and their standardization supervised by the hygienic laboratory of the service. One of the great pieces of work done by the United States Public Health Service was the creation of sanitary zones in the areas immediately surrounding the various cantonments.

Dr. Livingston Farrand, representing the American Red Cross, referred to its activities and achievements. From observations made during the first nine months after the United States entered the war and before our army had reached France, the Red Cross was a most powerful agency in upholding the morale of the French people, which was at a low ebb in the spring of 1917. The American Red Cross was likewise a powerful agency in winning the war. He paid an eloquent tribute to the women of America for having quickly prepared 300,000,000 surgical dressings. Everything was done by them that was called for.

Col. Henry B. Birmingham, representing the Association of Military Surgeons, stated that the membership of this association was now nearly 9,000, and as a result of the recent war he expressed the hope that the membership of this organization would be materially increased.

Dr. Lee K. Frankel, representing the American Public Health Association, spoke of the activities of this body, what it had accomplished, and what it hoped to do in the future with reference to preventive medicine.

Dr. David R. Lyman, representing the National Association of Tuberculosis, stated that the recent war made us realize the extent to which chronic diseases, tuberculosis, venereal diseases, etc., weighed on us and impeded progress. There were 61,964 men rejected on account of tuberculosis by the draft boards throughout the United States. His message to the people was that we must have universal military service, primarily, as the greatest of all public health measures.

Dr. Franklin H. Martin, representing the American College of Surgeons, recounted the activities of the members of this organization during war, stating that its membership was 4,000, 400 of whom were from the Provinces of Canada. Along with other societies, the members of the American College of Surgeons had offered their services to the government. He urged the 115,000 physicians who had offered their services so magnificently to the country to still stand by the government. They should not think of their disappointments but of the necessity of working for and aiding the government at all times.

THE SECOND VICTORY MEETING

Thursday Evening, June 12

This meeting was held in the Garden Pier, June 12, at 8:30 p. m., with President Lambert in the chair.

Dr. George E. Brewer, New York, spoke on some of the problems encountered by the medical department of the American army in the actual theater of war. A great change and great improvement in results had taken place in the treatment of medical and surgical conditions during the two or three years since the commencement of the war. He had received two vivid mental impressions. In the early spring of 1915, during the end of the first year of the war, he was on the staff of a small hospital near the front, associated with the sixth French army. He vividly recalled his first visit to a large hospital shortly after a sharp engagement in the neighborhood with every battle casualty of the graver type. During this visit he was deeply impressed by the evidence of great illness on the part of the wounded soldiers who occupied beds. One could see the hectic flush of sepsis, the patients lying with sunken eyes and with evidence of great prostration. There was not a single case of compound fracture that was not the seat of profound, deep seated infection. There was not a thoracic wound that was not accompanied by a grave complication of pneumonia or empyema. There were more cases of gas gangrene than he had previously seen in his entire professional life. The whole impression was one of surgical disaster because the soldiers were not receiving the best treatment on account of these conditions. All recognized that the wounds of this war differed from the wounds of civil life as they likewise differed from wounds in previous wars in their general character and extent, in their amazing multiplicity, and in their shocking and paralyzing effects from high explosives, with cruel lacerations of tissue and the highly virulent infections which accompanied them. How best to prevent or combat infection was the great problem of the military surgeon.

The second picture that Dr. Brewer painted occurred in the summer of 1917, when he went to France with the hospital unit with which he was connected. Of the military hospitals he saw shortly after arriving, none was so well equipped and so well organized as that under Professor Depage. In this hospital, with battle casualties of the same general character as he had previously mentioned, there was little evidence of sepsis. As one went through the wards, the patients looked cheerful and on the road to recovery. While there were some exceptions, the majority of patients looked well and were far from manifesting any depression. As he went into the operating and dressing rooms he saw that scrupulous technic always characteristic of this particular hospital. He saw no sepsis, and as a matter of fact, of the thousands of patients in that hospital there were very few suffering from septic infection. The picture in three years had undergone a remarkable change, as the result of three factors: First, a general recognition of the fact that the plan carried out in the beginning of the war of having the larger and most important hospitals and best surgeons in the rear was a failure. It was a great mistake. Second, there was developed during that period a splendid, careful, scrupulous technic which did much to overcome infection in battle casualties. Third, there was a general recognition of the fact that the golden opportunity was found to be between the receipt of the wound when it usually became contaminated and the point at which infection took place in the tissues, and if it were possible to receive wounded soldiers during that period, and careful débridement, first suggested by Professor Le Maitre, was carried out, the results were really remarkable.

Lieut.-Col. Sir Shirley Murphy, England, said that victory was never attained without some misfortune and loss of life. One of the most important events that had happened as a result of the war is that the two great nations, the United States and Great Britain, found they had interests in common, a community of interests, and a community of ideals. Both nations were striving to move forward hand in hand. This idea on the part of both nations had manifested itself very strongly during the last three or four years and could not help but be of enormous benefit to mankind. Of the various professions, the medical profession had done more than any other in the valuable service it had rendered to humanity.

In England they were contemplating work along the same lines that were being thought out in America, namely, a ministry of health, the inspection of schoolchildren, the inspection of boarding houses, of dealing with prenatal conditions—in a word, following the child from the cradle to the grave, or even before it is born.

Another point made manifest as a result of the war was the need for improvement in education, not only in the early days of the student's career, but in postgraduate training, so that there had been set up in Great Britain postgraduate lectures which enabled the members of the profession to keep in touch with the more recent knowledge which was from time to time being disseminated.

Rear Admiral Edgar R. Dimsey, England, said he considered it a great privilege and honor to bring good will from the British Navy Medical Society, to which he had the honor to belong, to the members of the American Medical Association. He expressed his appreciation of the extreme courtesy and kindness he had received from members of the medical profession in America, and that it would be his privilege and great pleasure to carry back to England the happiest memories of his visit to the great Victory Meeting of the Association.

Dr. Senichi Uchino, Tokyo, Japan, said that as a representative of his country he deemed it an honor to express his great pleasure at being present on this auspicious occasion. He emphasized the great work that the medical profession of America and of other countries had done during the recent war, both in the Army and the Navy, in working for a cause which reflected, not only the patriotism of their own country, but striving for justice to humanity. He referred to the progress made in sanitation and in the prevention of disease by American physicians, saying that it was remarkable, and that it had made a profound impression on the members of the medical profession of Japan. Japan owed much to America for the great progress made in the treatment of wounds during this war. He thanked the Association for the opportunity of addressing the members at this Victory Meeting and for the uniform courtesy and kindness extended to him as a representative of Japan.

Major S. T. Lee, China, said he considered it a great honor and pleasure to be present at this historic gathering of the American Medical Association, an Association which had no rival in its achievements in the world. He thanked the Association for the many courtesies extended to him personally, and above all he would carry away with him some very pleasant remembrances of his visit to the United States of America.

Surgeon-General Melis of the Belgian army said he felt much gratified to have the opportunity to bring cordial and fraternal greetings from the Belgian Medical Board to the United States. It was a great honor to take part in this Victory Meeting in America, a country which had given to the world so many great and generous ideas. In the recent war America had not only given freely of her immeasurable supply of men and material, but had done much for the great cause of justice and for the freedom of mankind. This war would redound to the glory of America. He predicted that this Victory Meeting would result in a stronger and more enduring fellowship among the members of the medical profession of the world. America, he said, had been a mother to Belgium, and he expressed the hope that the United States would continue to be a godmother of Belgium in every way in the future. In his double capacity as surgeon-general of the Belgian army and as president of the Belgian Red Cross, he extended his deepest gratitude and hearty appreciation to the whole people of America.

Col. J. S. Easby Smith, of the selective service regulations, Washington, D. C., stated that during the eighteen months of the draft there were 155 district boards, 12,079 local boards, and a total number of medical advisory boards of 9,577. The total number of physicians who actively and continuously, at an enormous sacrifice, aided in the selective draft was 26,419. One should bear in mind that there were 40,000 physicians acting in some capacity or another in the Army and Navy. The total number of registrants physically examined during the entire period of the draft was 5,719,152.

Colonel Smith then read extracts from General Crowder's report to the Secretary of War and to Congress, in which eloquent tribute was paid to the labors and efforts of the American Medical Association and the medical profession during the great crisis. Finally, during this present period of unrest, of reeducation and rehabilitation of our men, he urged the physicians of the United States to devote themselves to patriotic efforts in helping to carry on this great work.

The meeting was also addressed by Major Paul Bégouin, Bordeaux, France, and by Dr. Alexander Alexion of Greece, after which the meeting adjourned.

THE SCIENTIFIC EXHIBIT

The exhibits in the various booths in the Casino were as follows:

1. Exhibit of United States Department of Agriculture, Bureau of Chemistry.
2. Bureau of Census. Numerous charts showing rise and fall in the number of cases during the recent influenza epidemic.
3. Researches of toxic action of mustard gas, University of Michigan, by Dr. A. S. Warthin, and Dr. Carl V. Weller, showing lesions produced by mustard gas in various parts of the body.
4. Mayo Clinic. Treatment of high grade myxedema with thyroxin. Determination of metabolic rates following its injection. Studies on cholesterol. Isolation and identification of thyroxin. Roentgen-ray exhibit of mediastinal tumors, Hodgkin's disease, primary cancer of the lungs, cancer metastasis, gastric syphilis, and chronic ulcerative colitis. Experimental influenzal pneumonia by Edward C. Rosenow.
5. American Red Cross, first aid department. Numerous illustrations and diagrams of how to render first aid.
6. Council on Pharmacy and Chemistry of the American Medical Association. Exhibit of some of the work the Council has done, with literature on the subject.
7. Chemical Laboratory of the American Medical Association. Investigations the laboratory has made, and literature on the subject.
8. Propaganda Department, showing the work The Journal of the American Medical Association is doing in bringing to the attention of the public the facts regarding the nostrum evil and quackery, illustrated by numerous charts and booklets.
9. Council on Health and Public Instruction. In this booth there were a number of cartoons and hygiene charts and posters on baby welfare, together with a set of various booklets on child welfare, care of the baby in summer, and other publications of the Council.
10. Research Laboratory of Dr. Fenton B. Turck, New York. Work on autolysis and shock.
11. Exhibit of stereoscopic roentgenograms and stereo-Lumière photography by Dr. Emil G. Beck, Chicago.
12. Exhibit of roentgen-ray department, St. Luke's Hospital, New York.
13. Exhibit by members of the staff of the Battle Creek Sanitarium. Exhibit on dietetic management of diabetes. Roentgen-ray exhibit of gastro-intestinal diverticulosis, with duodenal diverticula. Roentgen-ray studies on the diagnosis of acute postoperative ileus. Some electrocardiagraphic studies and demonstrations of the technic and value of the Bergell carbohydrate tolerance test.
14. The Lying-In Hospital of the City of New York. Numerous charts of cases of normal pregnancy and charts of cases of preeclampsia and eclampsia.
15. Children's Bureau, United States Department of Labor, showing deaths under 1 year of age, grouped by cases; also deaths under 1 year of age by monthly age group, and reduction in infant mortality according to fathers' earnings.
16. Radium Therapy, by Dr. D. T. Quigley, Omaha. This was an excellent exhibit showing the results of the action of radium in cases of epithelioma, sarcoma, myxosarcoma, etc.
17. Charts of operations on the gastro-intestinal tract, based on physiology of the stomach and intestine, by Dr. J. Shelton Horsley, Richmond, Va.
18. Exhibit of chronic gonorrheal infections of the seminal vesicles, by Dr. Victor C. Lespinasse, Chicago. New technics on how to treat the chronically infected vesicle through the vas deferens. Percutaneous puncture of the vas and sensitiveness of the epithelium of the vas to irritants. Many of the commonly accepted antiseptics that are considered nonirritant will absolutely destroy the epithelium of the vas, producing stricture and consequent sterility.
19. Exhibit of Prudential Insurance Company, Newark, N. J., showing charts of influenza and respiratory diseases

in nine American cities during the epidemic period of 1918; also charts showing the prevalence and number of cases of influenza in England and Wales for several periods.

U. S. ARMY EXHIBIT AT EXPOSITION BUILDING

In connection with the Victory Meeting there was an exhibit at the Exposition Building by the Medical Department of the U. S. Army. There were seventeen different exhibits, covering all phases of the work which has placed the medical department on the high standard that it now enjoys.

The laboratory section showed the control of diseases in the various camps and also some excellent pathologic specimens, while the tests for the aviation service were very interesting. The sanitation exhibit had a complete set of sanitation models and photographs and charts illustrating methods of sanitation in the various camps and cantonments.

The section of reconstruction had complete work shops with the boys themselves at work, showing methods of education of wounded men.

The hospital division gave a complete description of the method of handling patients on their arrival at a hospital from overseas and their assignment to the proper wards. There were models of base hospitals and general hospitals. The division of surgery illustrated roentgen-ray work in the hospitals and in the fields, and many different styles of splints and their application were to be seen in the orthopedic section.

Perhaps the greatest success of surgery of the present age was shown in the maxillofacial section, where plaster and wax models of faces were to be seen, showing the work that was accomplished in this art during the great conflict.

The exhibit from the Army Medical Museum at Washington showed the treatment of wounds and skin diseases as perfected by the army medical department.

U. S. NAVY EXHIBIT AT EXPOSITION BUILDING

The U. S. Navy exhibit was carefully planned to represent the various activities of the medical department, and was arranged in such a way that it gave an excellent idea of the manner in which the recruits were received into the service and the provisions which were made for their medical care under the various conditions which might arise in the course of their service in the navy. The measures for the protection of the health of the naval personnel on board ship were exhibited by means of models of the battleships and other types of vessels. A large model of the medical department of one of the latest dreadnaughts presented an interesting picture of the medical and surgical facilities on board.

The arrangement for receiving and training recruits, and the methods of eliminating and controlling communicable diseases at training stations, were demonstrated by means of accurate models of dispensaries and isolation cubicles and by mechanical drawings.

For those who were interested in the more technical methods there was a complete mobile laboratory unit at work, illustrating the navy technic for the detection of meningococcus and diphtheria carriers; methods of preparing culture mediums, and the use of specific therapy.

The valiant land army, the marines, who formed a part of the navy, were represented by models and other interesting material from the great training center for the marines at Quantico, Va. Here was presented a very complete picture of the methods which were used to control an extensive malaria problem. By means of models, there was presented the work which was done to control thoroughly a large mosquito-breeding area.

One of the great activities which fell to the navy during the war was the transportation of the troops to and from Europe. This was represented by a model of the largest naval transport, the U. S. S. *Leviathan,* which showed how more than 10,000 troops were berthed and cared for during each trip.

The work of the central organization, the Bureau of Medicine and Surgery, was indicated by many charts, which showed the methods for the prevention and control of communicable diseases and for keeping constantly informed of health conditions in the navy, scattered as it was all over the world.

Among other things were shown complete statistics for influenza, tuberculosis and the venereal diseases.

Award of Prizes in the Scientific Exhibit at the Victory Meeting

The committee had great difficulty in judging between individuals and large organizations, such as government departments, representing an extensive corps of unnamed workers. In consideration of the manner in which awards have been made in the past, the committee felt that its functions would be best performed by laying emphasis on the excellence of individual effort. Accordingly, the awards are as follows:

Gold Medal—Dr. H. S. Warthin.
Silver Medal—Hideyo Noguchi.
Certificate 1—The Mayo Clinic.
Certificate 2—Dr. J. Shelton Horsley.

The committee desires to express its high appreciation of the interest and educational value of the U. S. government exhibits, and feels called on to commend those who have been instrumental in bringing to this meeting these splendid displays. The committee feels that special recognition should be given to the demonstrations made by the Medical Department and the Army and Navy, and by the Public Health Service.

Walter Cannon,
E. R. LeCount,
C. C. Bass.

FOREIGN DELEGATES AND GUESTS AT THE ATLANTIC CITY SESSION

Physicians from fourteen foreign countries were in attendance at the Victory Meeting. A list of these foreign guests follows:

Lehman, Wilmer S., Lolodorf, Cameroun, W. Africa
Casier, Baron Ernest, Belgium
Depage, Antoine, Belgium
Duesberg, J., Belgium
Melis, L., Brussels, Belgium
Nolf, P., Brussels, Belgium
Sand, Réné, Brussels, Belgium
Captain Van de Velde, Belgium
Chutro, Pedro, Buenos Aires
Aikins, W. H. B., Toronto, Can.
Bagshaw, Elizabeth, Hamilton, Can.
Buchanan, W. D., Peterboro, Ont.
Chartier, Aimé, Sorel, Quebec, Can.
Cleaver, Ernest E., Toronto, Can.
Clendenan, G. W., Toronto, Can.
Cody, William, Hamilton, Can.
Craig, Robert H., Montreal, Can.
Dibbie, W. J., Weston, Can.
Dixon, W. E., Grand Mere, Can.
Ewing, Francis James, Vancouver, Can.
Farris, H. A., East St. John, N. B.
Ferguson, W. A., Moncton, Can.
Fleming, Francis P., St. John, N.B.
Gallivan, James V., Peterboro, Can.
Hastings, Chas. J., Toronto, Can.
Hicks, E. S., Brantford, Can.
Hill, Clarence E., Toronto, Can.
Johnston, Samuel, Toronto, Can.
Kendall, W. B., Gravenhurst, Ontario, Can.
Lauterman, Maxwell, Montreal, Can.
Mallory, Fred, Toronto, Can.
Mann, Arthur H., Olds, Alberta, Can.
Minns, Fredk. S., Toronto, Can.
Mitchell, J. P., Toronto, Can.
Mowbray, F. B., Hamilton, Can.
Mullin, R. H., Vancouver, B. C.
Neal, Frank C., Peterborough, Can.
Rabinowitch, I. M., St. Anne de Bellevue, Quebec, Can.
Rawley, W. E., St. John, N. B.
Ross, George T., Montreal, Can.
Starr, Clarence L., Toronto, Can.
Sutton, A. B., Port Credit, Can.
Waldron, C. W., Montreal, Quebec, Can.
Willinsky, A. I., Toronto, Can.
Wishart, D. J. Gibb, Toronto, Can.
Young, William A., Toronto, Can.
Lee, S. T., Peking, China
Leonard, Eliza E., Peking, China
Ming-Shao, Hsu, China
Peter, William Wesley, Shanghai, China
Ting-han, Chang, China
Almila, E., Havana, Cuba
Carrera, Julio, Cuba
Fernandez, Francisco M., Havana, Cuba
Guiteras, Juan, Cuba
Martinez, Emilio, Cuba
Somodevilla, Santiago U., San Luis, Cuba
Kingman, E. L., Zaruma, Ecuador
Brown, W. Herbert, Glasgow, Scotland
Dimsey, Edgar R., British Admiralty
Groves, Ernest W. Hey, England
Hurst, Arthur F., England
Lane, Sir William Arbuthnot, England
Murphy, Shirley, England
Newsholme, Sir Arthur, England
Rose, Frank A., London, Eng.
Thompson, Sir St. Clair, London, Eng.
Bégouin, Paul, Bordeaux, France
Lemaitre, Fernand, France
Picqué, Robert, Bordeaux, France
Alexion, Alexander, Greece
Constas, John, Greece
Allen, Belle Jane, Baroda, India
Fletcher, A. G., Taiku, Japan
Kamimura, Asajiro, Tokio, Japan
Kodama, Ryuzo, Japan
Uchimo, Senichi, Tokio, Japan
Holst, Peter F., Norway
Muro, Felipe, Lima, Peru
Ingvar, Sven, Lund, Sweden.

THE SPIROCHETE OF INFECTIOUS HEMORRHAGIC JAUNDICE IN AMERICA

Only a few years have elapsed since Inada and Ido inoculated guinea-pigs with the blood of patients suffering from a form of infectious jaundice resembling Weil's disease and thus transmitted an experimental malady accompanied by jaundice, hemorrhage, albuminuria and other characteristic symptoms. The Japanese investigators then discovered both in the blood and various organs of the animals and in human specimens a new micro-organism, designated by them *Spirochaeta icterohemorrhagiae,* and since demonstrated without question to be the etiologic agent in Weil's disease.[1] On account of certain distinctive features of the infective organism, Noguchi[2] of the Rockefeller Institute for Medical Research has regarded it as a new genus for which he has suggested the name *Leptospira.* These spirochetes have since been examined in many parts of the world; and there is now no reason to assume that the Japanese, Belgian and American strains are other than identical.

Noguchi has found that rats captured in New York City and vicinity harbored the spirochete in question. He believes that the finding of the causative organism of infectious jaundice among wild rats in this country and the identification of this strain with the strains found on other continents is particularly important in that it reveals a latent danger to which we are constantly exposed. But New York is not the only community liable to be invaded by these neighborhood enemies. . Spirochetes capable of conveying hemorrhagic jaundice to guinea-pigs have been reported from Nashville[3] and from Washington.[4] According to a report just issued from the John McCormick Institute for Infectious Disease, Chicago rats are by no means free from the infectious organisms.[5] Spirochetes resembling those described as the cause of acute infectious jaundice were demonstrated in occasional animals —two out of thirty rats examined—indicating that they are probably not present in a high percentage of the rodents. Nevertheless, the spirochetes have been found, and this fact of itself constitutes a latent danger. They were demonstrated in material from the mouth and in tissue from the kidney. It is suggested by Otteraaen that, because of the presence of spirochetes in the mouths of rats, it is possible that, at the time of the bite, organisms may be carried into the wound by the saliva or teeth, and disease may in this manner be transferred directly from the rat to man.

The apparent immunity of rats to any noxious effect from the pathogenic organisms which they thus harbor is surprising. In some places more than one fourth of the rodents caught and examined have been found infected with the spirochetes, so that we must assume that a pronounced tolerance to them has been developed. If the present freedom of man from more widespread infection is to continue, suitable sanitary conditions in relation to this threatening factor in his environment must be maintained.

THE VICTORY MEETING

From every point of view the annual session of the Association held at Atlantic City last week must be considered a success. The attendance far exceeded the expectations of the most optimistic; the registration was 4,929, exceeding by nearly 1,000 the registration of the largest previous Atlantic City session, held in 1914; in fact, the registration this year has been exceeded only by that of the Chicago and New York sessions.

An unusual feature was the new arrangement for section meetings by which each section holds only one meeting a day. This plan was carried out by all of the sections except one, and the House of Delegates directed that the plan be continued.

The special VICTORY MEETINGS on Wednesday and Thursday evenings and the war sessions held Thursday afternoon, devoted to general medicine and surgery, were a novelty of this session. These meetings were well attended, the foreign guests and distinguished representatives of American organizations were enthusiastically received and the programs were instructive. Reports of these meetings appear in this and in the next number of THE JOURNAL.

The sessions of the House of Delegates were unusual especially because of the sociologic-medical aspects of the questions discussed. Narcotic addiction, social insurance, physical education, pharmaceutical interests, the publication of new journals, antivivisection legislation, daylight saving and the securing of permanent benefit from the medical work of the war—these were some of the subjects which engaged the attention of the House and on which definite recommendations were made or action taken. These are reported in the published minutes of the House of Delegates.

Among other attractions the scientific and commercial exhibits were exceptional both in the quantity and character of the material presented. In the scientific exhibit special notice should be given to the demonstrations by the Army and Navy Medical Departments and the Public Health Service of work both during the war and in preparation for peace. Connected with the scientific exhibit was a continuous motion picture performance in which were shown many new educational films.

Finally, it is not amiss to add here a note of thanks to the physicians of Atlantic City for their cooperation. Arranging for an annual session of the Association requiring numerous meeting places, large exhibit space and hotel accommodations for over 5,000 physicians and their guests is no small task. The aid given by an active local committee on arrangements is a determining factor in the success of the session.

METABOLISM IN PERNICIOUS ANEMIA

Pernicious anemia has assuredly not lacked investigation in recent years. The trend of the studies of this disease has been toward the more obvious abnormalities of the blood and the hemopoietic organs. There has been much searching for hemolytic compounds presumably elaborated in the disease processes and responsible for the great decrease in red blood cells. Many investigators have sought the cause of the anemia in some disorder of the gastro-enteric tract whereby harmful products of enterogenous origin are produced and absorbed. Indeed, from time to time, various chemical substances have actually been charged with responsibility for the uncontrollable hemolysis which brings about the untoward symptoms; but the proof for their etiologic rôle has in no case been firmly established.

Some of the pathochemical manifestations of pernicious anemia have recently been summarized by Kahn and Barsky,[1] who emphasize the familiar upset in the alimentary digestive functions. Helpful as such studies may be in the management of the diet and nutrition of patients, they fail to give anything like a complete picture of the metabolism in pernicious anemia. Most of the functions of the pancreas, liver and kidneys are reported as undamaged; and the hypothesis of the existence of "a state of suboxidation" as proposed by Kahn and Barsky hangs on extremely slender evidence. Far more striking are the calorimetric observations made by Meyer and Du Bois[2] on patients suffering from the disease. Their results show an increased metabolism in pernicious anemia, which was especially pronounced when the hemoglobin content of the blood fell to 20 per cent. of the normal. The explanation of this phenomenon observed with the Sage calorimeter has been problematic. Recent additional metabolic observations at the Peter Bent Brigham Hospital in Boston, by Tompkins, Brittingham and Drinker,[3] may furnish a key to the solution. They noted that before treatment the metabolism may be within normal limits or it may be above or below normal. After transfusion the metabolism always reaches a normal or diminished level. What is the interpretation of such changes? Transfusion produces a diminution of pulse rate and respiratory activity, and a drop in temperature if it has previously been elevated. But according to the Boston investigators the response of the metabolism to transfusion lags behind that of all the other factors by an interval of several days. The lowering of metabolism is, therefore, not due simply to a cessation of the compensatory muscular activity of the anemic individual. Tompkins, Brittingham and Drinker venture the opinion that in untreated acute cases it is evident that, outside of the heightened activity of the cardiac and other muscle, there is some type of stimulation to the body cells in general, and the amount of this stimulation is represented by the fall in metabolism after transfusion. There are coincident progressive tissue alterations which tend to reduce metabolism. These alterations are represented by the diminished metabolism of the chronic cases, and by the low level to which the metabolism falls in practically all cases as a result of transfusion.

On the basis of the foregoing hypothesis the lowered energy output of a chronic case of pernicious anemia represents the profound reduction in active tissue that is present in the terminal stages of the disease. In such conditions transfusion offers little promise of help. But in the earlier stages in which metabolism still remains at a normal level when the accelerated muscular efforts are excluded, some advantage may be expected. As the latest investigators[3] express it: While a course of transfusions does not prevent the development and progress of neurologic lesions, it does postpone the muscular sluggishness, which eventually reduces the chronic case of pernicious anemia to the state of a helpless burden. Relief always represents desirable therapy even if cure is seemingly impossible.

The Nursing Problem.—On the one hand, if artificial barriers are hindering women who could and would give good service at the bedside of the sick from rendering that service, those barriers must come down. Any standards of educational requirements and training maintained solely for the purpose of making the nursing field a closed preserve must give way before the public need. On the other hand, we may as well concede the annoying and deplorable fact that attempts to exact of nurses a degree of altruism and abnegation which are not expected of or practiced by any one else have slight chance of success.—*Modern Hospital.*

Current Comment

THE PRESIDENT-ELECT, SURGEON-GENERAL WILLIAM C. BRAISTED

The election of Dr. William C. Braisted, Surgeon-General of the Medical Department of the Navy, as President of the American Medical Association was particularly appropriate to the Victory Meeting. Thus the Association not only honors the man it elects but is itself honored. Dr. Braisted's career represents a steady progress through many delicate tasks and difficult assignments. He was born in Toledo, Ohio, in 1864, and was graduated by the University of Michigan in 1883, and by the medical department of Columbia University in 1886. He served as intern in Bellevue Hospital, New York, for two and one-half years, entering civilian practice in Detroit in 1888 and continuing until 1890, when he entered the Navy as assistant surgeon. He was promoted in 1893 to passed assistant surgeon, then to surgeon, and in 1913 to medical inspector. In the routine of a naval career he has served on a number of vessels and at many naval hospitals, and twice has been instructor in surgery in the naval medical school. In 1904 he fitted out and equipped the hospital ship *Relief*. During the Russo-Japanese War he went to Japan as the representative of the Medical Department of the United States Navy, and his report on this assignment was considered by the Japanese officials to be the most accurate and complete published. Surgeon-General Rixey appointed him assistant chief of the Bureau of Medicine and Surgery; he continued in this service for six years, from 1906 to 1912, serving also under Surgeon-General Stokes. During 1906 and 1907 he was attending physician at the White House. He acted as fleet surgeon of the Atlantic Fleet from 1912 to 1914, when he became Surgeon-General of the Navy with the rank of rear admiral. He has been decorated twice by foreign governments—first by the emperor of Japan and later by the president of Venezuela. Admiral Braisted is especially noted for the interest he has taken in preventive medicine. He has given particular attention to the control of venereal diseases. Under his administration the Department of Medicine of the Navy has made a most enviable record, as indicated by the remarkably low mortality and morbidity records of the men in the naval service. The election of Admiral Braisted at this time is especially fitting: it recognizes the service without whose aid the winning of the war would not have been possible.

Rear-Admiral William C. Braisted
Surgeon-General, U. S. Navy
President-Elect of the American Medical Association

MALNUTRITION CLINICS AND STUDENTS OF DIETETICS

Not long ago reference was made in The Journal to what may be accomplished in the case of malnourished or delicate children by the class method of dietetic and hygienic treatment described by Emerson[1] in 1910 and more recently by Smith.[2] The procedure is similar in many ways to that pursued in the classes for the tuberculous, and it aims at personal education and realimentation with the cooperation of both the patient and his family. There can be little question today that the problem of bringing many underweight children up to normal is largely one of diet. At the University of Chicago the needs of underweight children selected after competent medical examination from cases at the Central Free Dispensary of Rush Medical College were made the subject of attention of advanced students in academic courses in applied dietetics. According to Lydia Roberts,[3] who supervised the work, the children were all given thorough examination and all necessary medical treatment by the physicians, who then referred those in need of dietary help to the diet specialists, exactly as eye and ear cases were turned over to their respective clinics. Children in need of medical supervision reported to the physician each week before coming to the diet class; others with nothing at fault but diet and hygiene came directly to the class. The children met once a week on Saturday mornings. At the clinic the student took special charge of her own cases, listened to the discussion of the others, and helped prepare food exhibits, diet slips, and recipes needed in the class. She made at least one home visit each week, saw that the child attended the clinic regularly, and was held personally responsible if he lost or failed to gain. The results from such beginnings in an enterprise beneficial alike to patient and to student are reported to be gratifying. Parents have been educated, poor hygiene has been corrected, home living conditions have been improved, and, above all, gains of weight have been induced. Food, particularly milk, sleep, and better dietary habits, have contributed most to the favorable outcome. This success, though representing only the beginnings of what may become a large sociological and hygienic enterprise, furnishes an added illustration of the mutual advantage of contact between a student and a patient in the modern scheme of clinical instruction.

FAT ABSORPTION IN INFANCY

The consideration of the quantity of "fat," in the form of either neutral fat, fatty acid or soap, in the stools of infants takes a prominent part in the clinic of diseases of childhood. There have been periods within the past few decades when the question of the digestion and absorption of fats in the alimentation of infancy has almost seemed, to those not solely concerned with problems of this sort, to receive an emphasis out of all proportion to its comparative significance. The starting point for the estimate of good, tolerable or deficient utilization of fats and the diagnosis of any disorders consequent on a disturbance of this function lies in a knowledge of what constitutes the normal condition in health. In the case of the adult, the statistics on this point are concordant and conclusive for a considerable number of fats of both animal and vegetable origin. Ninety-five per cent. or more of ingested fat ordinarily is absorbed, so that even when it is consumed in amounts above 100 gm. (3⅓ ounces) the utilization of fat may be regarded as excellent in the healthy person. These established findings are now supplemented by new statistics from breast fed infants in this country. Analyses made by Holt, Courtney and Fales[1] of New York on the feces of thirty well nourished infants who were gaining normally shows a range of fat absorption of from 90 to 99 per cent. of the intake. The fat of the stools averaged 34.5 per cent. of the dried weight, and frequently was as high as 50 per cent. About one third was in the form of soaps. In absolute amounts, the daily fecal excretion of fatty material rarely exceeded 2 gm., and was sometimes less than 0.5 gm. Here, then, is another illustration of the danger of thinking in terms of percentage composition when small quantities are involved. A stool may be half fat, and yet that half may amount to only a gram or two in absolute quantity, when little alimentary residue appears as feces. According to the New York investigators, no constant relation was shown between the percentage of fat in the mother's milk and the percentage of total fat in the stool.

SHOCK AND FAT EMBOLISM

Among the numerous theories to account for the production of shock as observed at the front during war time the hypothesis that it is due to fat embolism has been frequently mentioned. Porter, who visited the battlefields of France to study shock, has strongly championed the explanation cited. In his essay on "Shock at the Front"[1] he wrote:

> I have myself examined more than a thousand wounded. Save a few wounds of the abdomen, in which the blood vessels or their nerves in that great vascular region were probably directly injured, there has been no case of shock except after shell-fractures of the thigh and after multiple wounds through the subcutaneous fat. In these, closure of the capillaries by fat-globules is known to take place. This is strong support for my discovery that shock may be produced in animals by injecting fat into the veins.

Numerous investigators, however, have taken exception to this seemingly simple explanation of how shock originates. For instance, the investigation of what actually happens to animals subjected to severe concussion of the sort that provokes "explosive shock" has included a study of the possible presence of fat in the blood vessels. Intravascular fat in the form of droplets of widely varying sizes has been commonly found. Unfortunately for the embolism hypothesis, intravascular fat has been found in the same localities in normal animals of the same species. McKibben,[2] at the Army Neurosurgical Laboratory at the Johns Hopkins Medical School, demonstrated the presence of fat in the blood vessels of all the animals examined, no matter whether they had been shocked by air concussion or not. No quantitative or qualitative differences have been detected between the fat found in the vessels of the shocked animals and the intravascular fat of normal ones. The same is true with respect to the intravascular fat found in prolonged anesthesia. Any hypothesis of shock by fat embolism must take cognizance of these facts.

ANDREAS CAESALPINUS

The present year marks the four-hundredth anniversary of the birth of Caesalpinus, the botanist and writer on medical topics, to whom, along with Servetus, Realdus, Columbus and others, the discovery of some of the fundamental principles of the circulation of the blood has been ascribed in days gone by. It has been remarked that all great men have their detractors. Harvey, the real discoverer of the circulation of the blood, has been no exception to this statement. Nevertheless, his fame rests so securely in our day, and the immense significance of the method of study which he employed in relation to the circulation is so generally admitted, that the alleged claims of others to priority need give us no concern. At most, the circuit of blood through the lungs had been only vaguely defined before Harvey published his epoch-making work. Caesalpinus was among those who entertained ideas about the movement of the blood. To his credit, it may be said that he was bold enough to shake off the domination of galenic theories. Caesalpinus seemingly grasped the possibilities of the pulmonary circulation. He "recognized that the flow of blood to the tissues took place by the arteries and by the arteries alone, and that the return of the blood from the tissues took place by the veins and not by the arteries." With Sir Michael Foster[1] we are inclined to believe, however, that the conclusions of Ceasalpinus were the result of controversial argument rather than of patient research, such as characterized Harvey's transcendent discoveries. There is no record of observations or experiments in the writings of Caesalpinus. We may therefore point to his failure to reach a real goal as an illustration of the incomparable superiority of the true scientific method. Even today, more than three centuries after the events recorded, the foremost reason why Caesalpinus failed whereas Harvey succeeded deserves to be brought home anew to those who tread the paths of the medical sciences.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending June 13, there were 13,931 officers in the Medical Corps, a decrease of 975 from the previous week. The Medical Reserve Corps contained 2,414 officers. The total number of medical officers discharged since the beginning of the war is 18,056.

Bulletin A. E. F., Final Number

(June 2, 1919)

Some interesting figures are presented as to pathologic studies made by the pathologists of the A. E. F. The records include 14,000 protocols made by 450 pathologists. Two hundred and sixty-eight of the pathologists have been graded as good or very good on the basis of their scientific and technical knowledge; 180 were classified as fair, and two as very poor. The record will be kept on file in Washington, and will be available for study.

STATISTICS ON TYPHOID AND PARATYPHOID

The complete figures on typhoid and paratyphoid fever in the A. E. F., including Italy and Russia, are published in this issue of the Bulletin. The tabulation follows:

	Typhoid		Paratyphoid	
	Cases	Deaths	Cases	Deaths
1917*—

* No cases or deaths reported in July, 1917.

MONTHLY REVIEW

The onset of fair weather in April, continuing throughout May, has caused a reduction in all communicable diseases.

Appropriation for Medical Department, U. S. Army

The sum of $5,000,000 is authorized to be expended for supplies for the medical and hospital department of the United States Army during the fiscal year beginning July 1, 1919, in the Army appropriation bill now under consideration by Congress. This appropriation includes many specific items necessary to the operation of the Surgeon-General's department. The Surgeon-General is authorized to spend an additional $20,000 for the purchase of books and periodicals for the library of the Medical Department and $10,000 is authorized for the purchase and preservation of specimens for the Army Medical Museum. The Surgeon-General is directed to expend $60,000 for the care of officers and enlisted men in hospitals in the Canal Zone. For paying nurses, $80,000 is authorized; for contract surgeons, $90,000; for reserve veterinarians, $350,000; for hospital matrons, $3,600.

HONORABLE DISCHARGES, MEDICAL CORPS, U. S. ARMY

Note.—In the following list, L. signifies lieutenant; C. captain; M., major; L. C., lieutenant-colonel, and Col., colonel.

ORDERS TO OFFICERS OF THE MEDICAL CORPS, U. S. ARMY

On account of lack of space, due to publication of proceedings of the Annual Session, "Orders to Medical Officers" are omitted in this issue.

Birth Statistics.—The U. S. Census Bureau's preliminary report for 1917 shows that in the birth registration area of the United States 1,353,792 infants were born alive in 1917, representing a birth rate of 24.6 per thousand of population. The total number of deaths in the same area was 776,222 or 14.1 per thousand. The births exceeded the deaths by 74.4 per cent. For every state in the registration area, for practically all the cities and for nearly all the counties, the births exceeded the deaths, in most cases by considerable proportions. The mortality rate for infants under 1 year of age averaged 93.8 per thousand living births. The birth rate for the entire birth registration area fell below that for 1916 by two-tenths of one per thousand population, but the death rate was less by six-tenths of one per thousand than in 1916. Thus the excess of the birth rate over the death rate for 1917, which amounted to 10.5 per thousand, was somewhat greater than the corresponding excess for 1916, 10.1 per thousand, although it fell slightly below that for 1915, 10.9 per thousand. If the birth and death rates prevailing in any one of these three years were to remain unchanged, and if no migration were to take place to or from the area to which they relate, its population would increase at the rate of slightly more than 1 per cent. per annum, or a little more than 10 per cent. in a decade. This would be about half the rate, 21 per cent., by which the entire population of the United States increased between 1900 and 1910.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALASKA

Influenza Epidemic.—Influenza in most serious form is reported to be epidemic in Alaska. The Bristol Bay section is most seriously involved. The epidemic appears to be attacking both whites and natives with a high percentage of mortality. In one small settlement sixty deaths are said to have been reported in one day. The ships of the Pacific Squadron of the Navy, and the Coast Guard Service have been given hurried orders to proceed to Alaska with additional medical officers and hospital corps men.

CALIFORNIA

Personal.—Dr. Ray Lyman Wilbur, president of Leland Stanford University, has been elected president of the California State Conference of Social Agencies. President Wilbur has always taken particular interest in the sociological problems connected with diseases, and brings to his new duties a wide practical experience and a splendid record of past accomplishments.——Henry S. Kiersted, M. C., U. S. Army, Burlingame, was elected surgeon of the California Commandary Military Order of Foreign Wars of the United States at its meeting for organization at San Francisco, May 8.

DISTRICT OF COLUMBIA

Senate Committee on Public Health.—The membership of the full Senate Committee on Public Health and National Quarantine has been announced. The members are Senator Joseph I. France, Maryland, chairman; Senator Charles E. Townsend, Michigan; Senator Joseph S. Frelinghuysen, New Jersey; Senator Boies Penrose, Pennsylvania; Senator Warren G. Harding, Ohio; Senator L. Heisler Ball, Delaware; Senator Joseph E. Ransdell, Louisiana; Senator Duncan U. Fletcher, Florida; Senator Robert L. Owen, Oklahoma; Senator Oscar W. Underwood, Alabama; Senator William J. Harris, Georgia. The first six are Republicans and the last five Democrats. Strange as it may seem, the House of Representatives has no committee on public health, medical bills being referred to a number of committees, largely to military affairs and the judiciary committee. It is to be hoped that the medical profession will insist that a committee to act on medical legislation matters be named by the House at no far distant date.

ILLINOIS

Personal.—Dr. William M. Hanna, Aurora, has been elected medical director of the Grand Army of the Republic for Illinois.——Dr. Irving H. Neece, Palmyra, assistant surgeon, U. S. P. H. S., has been appointed health officer of Decatur.

Drugs at Great Lakes.—Joseph W. Robinson, said recently to have been an enlisted man at Great Lakes was arrested, June 14, while carrying a cigar box containing nearly $1,000 worth of cocain and opium. It is believed that the arrest of Robinson may be the link needed for solving the mystery in a number of "dope cases" which occurred at the U. S. Naval Training Station, in April.

Chicago

Personal.—Norman M. MacNeill, Capt., C. A. M. C., formerly resident physician at St. Joseph's Hospital, has been appointed adjutant of the Granville Canadian Hospital at Buxton, Derbyshire, England.——S. N. Trockey, Capt., M. C., U. S. Army, has returned after service with the British Forces in France.

Alumni Elect Officers.—At the annual meeting of the Northwestern University Medical Alumni Association held in Chicago, June 16, under the presidency of Samuel C. Stanton, Major, M. C., U. S. Army, the following officers were elected: president, Dr. William E. Quine, '69; secretary, Dr. Alexander A. Goldsmith, '01; and necrologist, Samuel C. Stanton, Major, M. C., U. S. Army, '92. On the mornings of June 16 and 17, instead of the usual clinic week, addresses were delivered to the Alumni at the school, by members of the faculty and alumni who had been in war service.

INDIANA

Tuberculosis Hospital Items.—New buildings are to be erected at Sunnyside, the Marion County Tuberculosis Hospital. There is to be a cottage for tuberculous children and a service building with kitchen, dining room and workshops. It is also hoped to erect soon a cottage for incipient cases with a capacity for twenty patients. The buildings will have all the latest improvements for the treatment of tuberculous patients. Dr. Harry S. Hatch, the superintendent, says that the needs are urgent for the better care of tuberculous children, as the work in checking tuberculosis is more effective among children than with the more advanced cases among adults.——The Indiana State Tuberculosis Hospital, Rockville, has been renamed the Indiana State Sanitarium. Dr. Amos Carter of Plainfield was chosen for superintendent, succeeding Dr. Raymond B. T. Sweany.

IOWA

Personal.—Dr. Harold L. Beye, assistant professor of surgery at the State University of Iowa, Iowa City, who has been on duty with the American Expeditionary Forces in France and who was gassed, has been released from the hospital and has returned home.——Dr. Alford J. Farnham, Traer, has been elected president, and Dr. Percy L. Parsons, Traer, secretary, of Tama County Medical Association.

New Health Laws.—A housing law has just been passed in Iowa. The law proposes minimum specifications for future building in cities of 15,000 population or over; also the reconstruction or rehabilitation of tenements or dwelling houses; the control of yard space, air space in living and sleeping quarters and other regulations tending toward the preservation of health of the people. This law is primarily a health measure which connotes economic and social welfare. Another law authorizes boards of supervisors, city and town councils, and boards of education to employ public health nurses. A venereal disease bill was passed and an appropriation of $15,000 made for the education of people on venereal diseases and their control. The government appropriates dollar for dollar, making an additional $15,000 for this work. The campaign against tuberculosis is admitted to have contributed no small influence to the passage of this legislation.

MARYLAND

Hospital Overcrowded.—Because of the abandonment of the hospitals for wounded soldiers at Cape May, N. J., and at St. Louis, whose patients are to be transferred to U. S. Army General Hospital No. 2, Fort McHenry, the capacity of that hospital will be taxed to its utmost, as there are already about 2,000 patients under treatment at the fort. About 1,000 men are expected from the two discarded hospitals.

Hospital Site Chosen.—A site adjacent to the Eudowood Sanatorium, Towson, has been selected for the new state tuberculosis sanatorium for negroes. The selection was made by the board of managers of the State Tuberculosis Sanatorium, Sabillasville. The last legislature appropriated a total of $75,000 for the sanatorium, of which $50,000 is available during the current fiscal year and $25,000 during the next. There will be about $50,000 left after the purchase of the land and this will be used to build first units of the hospital.

Personal.—Charles M. Remsen, Major, M. C., U. S. Army, Baltimore, who sailed for France last August and was connected with Evacuation Hospital No. 2 during the fighting in the Argonne region, has been promoted to the rank of lieutenant-colonel, and is now with the army of occupation at Coblenz.——Dr. William Kelso White, Baltimore, who for the past year has served overseas with the Medical Corps, U. S. Army, has returned and is now stationed at Camp Dix, N. J., awaiting discharge.——Dr. Henry A. Naylor, Pikesville, who served with the rank of captain in the Medical Corps, Sixtieth Pioneer Division, has received his discharge.

MASSACHUSETTS

Division of Public Health.—The Massachusetts State Department of Health announces the creation within the division of hygiene of a subdivision of public health nursing. Included in this subdivision will be the nurse health instructors of the division of hygiene.

Lawrence Establishes a Community Welfare Council.—May 14, the health and social agencies of Lawrence, united to form a community welfare council with the president of the chamber of commerce as chairman. The council intends to coordinate the work of the established organizations and to serve as a committee to develop the public health work of the city.

New England Child Welfare Conference.—At Boston, May 15 and 16, the New England Conference on Child Welfare was successful in bringing together from all the New England States about one thousand representatives of organizations devoted wholly or partly to children's work. This is one of the series of regional conferences on child welfare which have been arranged by Miss Julia Lathrop, Chief of the Federal Children's Bureau, to take place in different sections throughout the United States. The exchange of ideas and experience among English, Belgian, French, Japanese, Italian, Servian and American delegates is giving added strength to public opinion in favor of the efforts of child welfare organizations.

NEW YORK

Special Meeting on Narcotic Situation.—As a result of a petition of members of the Medical Society of the County of New York, a special meeting of the society has been called for June 23 to discuss the narcotic drug situation, especially with reference to the amendment to the sanitary code proposed by the commissioner of health.

Personal.—Charles S. Little, Capt., M. C., U. S. Army, superintendent of Letchworth Village, has returned from France, and on his discharge will resume his former position. ——Dr. Erick H. G. Restin, Liberty, has been appointed medical superintendent of Rockland County Tuberculosis Hospital.——Dr. Robert H. Irish, Troy, has been selected as head of the Tuberculosis Dispensary and the Visiting Nurse Service of Troy.

Victory Meeting of Buffalo Alumni.—The forty-fourth annual meeting of the Alumni Association of the Medical Department of the University of Buffalo was held in Buffalo, June 19 to 21, under the presidency of Dr. William F. Jacobs, Buffalo. The first day there was a symposium on war medicine and surgery by members of Base Hospital No. 23. In the evening class reunions were held. On the second day the alumni oration in medicine, on "Facts and Theory in Practice," was delivered by Dr. Frederick Peterson of New York City, and the fraternity reunions were held. On the third day of the meeting, the alumni victory dinner was given in the banquet hall of the Hotel Statler.

Narcotic Pledge by Bay Ridge Physicians.—At the regular meeting of the Bay Ridge Medical Society, June 5, a resolution was adopted whereby the members pledged themselves to try in every possible and reasonable way to cure addicts and alcoholic inebriates and pledged themselves not to prescribe drugs or alcoholic liquors merely for the purpose of satisfying a craving therefor. The establishment by the government of hospitals for the treatment of alcoholic and drug addicts was also recommended. The society approved a contribution of $5,000 toward the proposed Victory Memorial Hospital, Bay Ridge, which is to cost $100,000 and is to be erected as a tribute to the service men of Bay Ridge, living and dead, and the following officers were elected: Dr. Rollin Hills, president; Dr. Joseph W. Malone, vice president; Dr. James W. Fox, secretary, and Dr. John J. Masterson, treasurer.

New York City

Osteomyelitis Service.—A special service for the treatment of osteomyelitis is being conducted at U. S. Embarkation Hospital No. 4, 345 West Fiftieth Street, under the direction of Dr. Pedro Chutro, formerly director of the Hospital Buffon, Paris, and George W. Hawley, Lieut.-Col., M. C., U. S. Army. Lectures and demonstrations are given daily, except Saturdays, from 2 to 4; ward dressings daily from 9 to 11 a. m.; and operations are performed every Monday, Wednesday and Friday at 10 a. m.

OHIO

Venereal Disease Cases Reported.—Figures given out by the state health department, June 9, showed that the enforcement of the regulations requiring physicians to report to the department all cases of venereal disease in their practice are producing results. During the months of April and May, 1,693 venereal disease cases were reported, while during the corresponding period last year there were 626 reports of the disease.

Personal.—Fred Fletcher, Major, M. C., U. S. Army, Columbus, has been promoted to the rank of lieutenant-colonel, and is in charge of Base Hospital No. 38, at Nantes, France.——Dr. W. N. Unkeefer, Piqua, underwent an operation at the Memorial Hospital, June 3, and is reported to be doing well.——John D. O'Brien, Lieut.-Col., M. C., U. S. Army, Canton, chief of the medical services at LeMans, France, returned home, May 31.——Dr. Edward D. Allgaier, Cincinnati, has been appointed surgeon to the eye, ear, nose and throat service of St. Francis Hospital, succeeding Dr. John Ranly, deceased.

OREGON

Damages Against Physicians.—In a suit brought by Fred Barton against Drs. Ralph C. Matson and Ray W. Matson, Portland, in which $20,000 damages were asked on account of serious injury alleged to have resulted from leaving of a drainage tube in the lung, the plaintiff, May 28, is said to have been awarded $2,000 damages.

University of Oregon News.—The seventh annual meeting of the Alumni Association of the Medical Department of the University of Oregon will be held in Portland, June 23 to 25, immediately preceding the meeting of the Oregon State Medical Association, which is to be held June 26 to 28. From June 30 to July 10, the faculty of the university will give postgraduate courses for which a small fee will be charged.

PENNSYLVANIA

Personal.—Henry M. Thissell, Lieut., M. C., U. S. Army, Philadelphia, Pennsylvania Reserve Militia, has been relieved from active service and transferred to the supernumerary list.——Dr. Alphus W. Gregg, Kennett Square, was acquitted, June 4, of charges of improper medical treatment preferred by William and Anna Scott.

Philadelphia

Personal.—Surg.-Gen. L. Melis of the Belgian army, Prof. Jules Deusberg and Dr. Pierre Nolf, all of whom are from Liege, Belgium, were guests of the City Club at luncheon, June 7.

Medical Club Reception.—The Medical Club of Philadelphia gave a reception, on the evening of June 18, at the Bellevue-Stratford Hotel, in honor of Senator Robert L. Owen, Oklahoma, and the foreign delegates to the American Medical Association.

Hahnemann to Admit Women Students.—For the first time in seventy-one years women will be admitted to Hahnemann Medical College according to the announcements of Dr. Henry M. Eberhard, member of the faculty, and the admission of women to the institution will be made possible through the gift of $40,000 by W. E. Hering, whose father, Dr. Constantin Hering, was one of the founders of the college. This substantial fund was added to the Hering foundation funds and the interest on this additional endowment will be used for both men and women who could not otherwise afford a medical education. Living expenses as well as tuition will be provided by this fund.

TEXAS

Personal.—Dr. Dabney Berrey, San Antonio, has been appointed health officer of Bexar County.——Dr. Henry B. Decherd, Dallas, has been elected vice president of the University Club, Dallas.——Dr. Alden Coffey, Fort Worth, suffered severe bruises in an automobile collision, June 5.

North Texas Physicians Hold Meeting.—At the seventeenth semiannual meeting of the North Texas Medical Association held in Dallas, June 4, Fort Worth was selected as the next place of meeting and the following officers were reelected: president, Hugh Leslie Moore, Dallas, for the eighteenth term; vice president, Dr. Sidney J. Wilson, Fort Worth, secretary, Dr. David L. Bettison, Dallas, and treasurer, Dr. Martin L. Wilbanks, Greenville.

Health Department to Be Reorganized.—Complete reorganization of the health department of Dallas was authorized, May 16, at the session of the board of city commissioners, when ordinances were approved creating a board of hospitals and a board of health, and designating its duties. In the hospital board, which will consist of the mayor and nine members, there will be a superintendent of hospitals and a superintendent of emergency and home service. The health board, which consists of the mayor and twelve members, will conduct the work of the director of public health, and will be directly in charge of four branches of the city health office, namely, the city health officer, city sanitarian, city chemist and city registrar. Drs. Thomas J. Crowe, Joseph W. Bourland, Calvin R. Hannah, L. V. Lataste and Albert A. Jackson, Mexia, who resigned from the original board of health, have been reappointed members of the board of hospitals together with Dr. William C. Swain, and three laymen. The board of health consists of Drs. John W. Embree, Samuel M. Freedman, John. G. McLaurin, Oscar M. Marchman, J. J. Simmons, all of Dallas, and six laymen.

WASHINGTON

Personal.—Dr. Ernest F. Pope, Spokane, who returned to America from France, in April, is under treatment in the Peter Bent Brigham Hospital for thrombosis following pneumonia.——The charges of alleged misconduct made against Dr. Ralph Hendricks, city health officer of Spokane, have been investigated and have been found not to have been sustained.——Dr. Andrew M. Flynn, Tacoma, was held up and robbed in front of his residence, May 4.——Dr. Charles E. Eaton, Seattle, has been discharged from the Army after two years' service and has resumed practice.——William L. McClure, Major, M. C., U. S. Army, North Yakima, on duty in France, has been promoted to the rank of lieutenant-colonel.

WISCONSIN

New Officers.—At the annual meeting of the Wisconsin Surgical Association held in Milwaukee, May 8, Dr. William C. F. Witte, Milwaukee, was elected president; Dr. Karl W. Doege, Marshfield, vice president, and Dr. Daniel Hopkinson, Milwaukee, secretary-treasurer.

Personal.—Dr. John G. Barnsdale, Superior, convicted of violating the antinarcotic act, and denied further hearing, was taken by United States Marshall to Fort Leavenworth, June 11, where, in addition to a three year term in the penitentiary, he has been sentenced to pay a fine of $6,000.

WYOMING

New Hospital.—The new hospital for Laramie County, to be erected at Cheyenne, is to be known as the Frances Pershing Memorial Hospital in accordance with a contribution of $25,000 toward its cost to be made by Senator Francis E. Warren and Fred E. Warren. The hospital will cost $200,000, $75,000 of which is to be raised by the sale of the hospital bond issue and the remaining $100,000 by a special tax levy. Work on the building, which will occupy a portion of the grounds of the present Laramie County Hospital, will be commenced as soon as plans can be completed.

CANADA

Ontario Government to Manufacture Arsphenamin.—The Ontario Board of Health has been advised that the federal government at Ottawa has approved of its application to manufacture and sell arsphenamin. Dr. John W. S. McCullough, Toronto, chief officer of health for Ontario, claims that this privilege will be of the greatest importance in combating syphilis in Ontario.

Centers for Research in Ontario.—Hospital superintendents from Ontario met recently in Toronto at the call of the provincial secretary under whose department the hospitals of the province are administered. The efficiency and standing of these public institutions were discussed, and it is now the intention of the department to rebuild and staff those hospitals which were depleted of regular scientific help during war time. One of the largest and finest of these institutions, the one at Whitby, was handed over to the Department of Militia and Defense early in the war period; and the Central Prison at Guelph was also made use of as a convalescent hospital for returned soldiers. The Whitby institution will revert to the department at the end of June, and it is planned further to improve this institution and make it one of the finest hospitals for mentally afflicted in the world. In each hospital district of the province a medical center will be located.

GENERAL

President Wilson Congratulates New President of Association.—In recognition of the recent election of Surgeon-General William C. Braisted to the Presidency of the American Medical Association, President Wilson on June 17 cabled to him from Paris his personal congratulations.

Appropriation for Study of Influenza.—The Committee on Scientific Research of the American Medical Association has made an appropriation for the preparation of a critical summary of the epidemiology and bacteriology of the influenza pandemic. The work has been placed in charge of Prof. Edwin O. Jordan of the University of Chicago. It is requested that reprints of articles and statistical records on influenza be forwarded to Professor Jordan as soon as published.

Bequests and Donations.—The following bequests and donations have recently been announced:

Loomis Sanatorium, Saranac Lake; N. Y., $10,000, Association for Improving the Conditions of the Poor, New York City and Monmouth, N. J., Memorial Hospital, each $5,000 by the will of Mrs. Henrietta Kingsland.

To endow the Jane Dowst Emergency Hospital, Waukegan, Ill., $150,000, on the death of his sister, by the will of Charles Dowst, Waukegan.

Health Education Legislation.—"Health extension education" is provided for in a measure introduced by Senator Sheppard of Texas. The work would be directed by the U. S. Bureau of Education and the Public Health Service. A general work of education of civic and public health nature is to be conducted in all states accepting the service and a federal appropriation of $10,000 is provided for each state. The work would be carried on through the extension departments of the state universities. The purpose of the measure is to "establish and promote civic, social and health extension education."

Increase in Drug Addicts.—The special investigating committee of the Treasury Department in its final report, submitted, June 13, states that the nation-wide use of narcotic drugs for other than legitimate medical purposes has been steadily increasing in the United States during the last four years, despite vigorous efforts in the enforcement of the federal law; the number of drug addicts in the United States is estimated to be in excess of 1,000,000, and that imports of opium products and coca leaves into the United States have increased twice as rapidly as the growth of population.

Division of Tuberculosis Under Public Health Service.—The creation of a division of tuberculosis in the Public Health Service is provided for in a bill introduced by Senator Ransdell of Tennessee. The bureau is to be in charge of an assistant surgeon-general. The duties of the bureau are "to study tuberculosis and its causes and prevention and to demonstrate methods for its suppression." The establishment of an advisory council on tuberculosis is provided. The council is to consist of "ten competent men selected because of their special knowledge relating to public health," appointed by the Surgeon-General of the Public Health Service. Two members are to be retired each year. Their compensation would be $10 per diem and expenses. The Hygienic Laboratory Advisory Board, created by the act of July 1, 1902, would be abolished by the bill.

More Social Hygiene Appropriations.—The United States Interdepartmental Social Hygiene Board announces appropriations from its scientific research fund to the following institutions for the purpose of investigating "more effective medical measures in the prevention and treatment of venereal diseases":

University of Nebraska College of Medicine: (*a*) Investigation relative to the development of an internal urinary antiseptic. (*b*) Investigation of the value of certain anilin dyes in the treatment of gonorrhea. Both under the direction of E. G. Davis, M.D., director of pathological laboratory.

St. Louis University College of Medicine: Studies in infection by gonococci. Under the direction of Ralph A. Kinsella, M.D., director of department of experimental medicine.

Woman's Medical College of Pennsylvania: A serologic study of syphilis in pregnant women and new-born children with special reference to the efficacy of the accepted methods of syphilitic treatment. Under the direction of Bertha M. Meine, M.D., director of research department.

Washington University School of Medicine: The laboratory (biologic) investigation of the latent syphilitic as a carrier. Under the direction of Martin F. Engman, M.D., professor of dermatology, St. Louis.

Cornell University Medical College: Serologic study of the gonococcus group. Under the direction of John C. Torrey, Ph.D., professor of hygiene.

Jefferson Medical College of Philadelphia: A series of studies for the recognition and diagnosis of *Spirochaeta pallida* in venereal diseases and the effect of various drugs and materials as germicidal agents against *Spirochaeta pallida*. Under the direction of Randle C. Rosenberger, M.D., professor of hygiene and bacteriology.

FOREIGN

Infant Welfare Clinics in Greece.—The American Red Cross has established a number of infant welfare clinics in Greece where many young women of the highest classes of Greece are instructed in infant welfare, trained as nurses' aids, and are given clinical demonstration as to how children should be treated.

Protection of Students in Dissections and Laboratory Work.—A Spanish medical student, F. Simon, died last March from infection acquired in the class of practical anatomy at the University of Madrid. His father has recently founded an endowment of 12,500 pesetas the income of which is to be expended in protecting medical students against the dangers inherent in dissecting work, in laboratory research, and in aiding at operations.

Organization of Spanish Medical Association.—Among the conclusions voted at the First National Medical Congress, held at Madrid in May, was the organization of the Asociación Médica Española. As there was no opportunity for discussion of constitution and by-laws, a draft closely following the constitution and by-laws of the British Medical Association was adopted temporarily. The medical congress and its annex proved a great success for the first attempt at a national gathering of the kind in Spain. The lay attendance at the exhibition was surprisingly large.

Medical School in China Opens.—The Peking Union Medical College, Peking, China, which has been built under the direction of the Rockefeller Foundation, will open for the instruction of students in October, 1919. The college will give a four years' course in medicine and an additional year of special work in hospitals or in laboratories. The school will be coeducational. There is also a premedical school offering a three years' course preparatory to admission to the medical school. This premedical school was opened in September, 1917.

Prize for Work on Radiology.—The French Society for Medical Radiology founded an annual prize of 300 francs for the best article on some radiologic subject presented in competition. The war interrupted the custom but the society now announces that the prize will be awarded this year, and states that all competing articles must be in the hands of the secretary before Oct. 1, 1919. Address Dr. Haret, rue Pierre-Haret, 8, Paris IX. Full details in regard to the prize offer were given in the *Bulletins de la Société de Radiologie*, March, 1914, p. 112. Five copies of the article must be presented.

Deaths in the Profession Abroad.—Dr. A. Lecha-Marzo, professor of legal medicine at the University of Sevilla, Spain, aged 31. At the age of 18 he published an article on hemochromogen crystals as a means of identifying blood, and later communications on dactyloscopy and on the tear sign of actual death carried his name far and wide.——The *Nederlandsch Tijdschrift* mentions the death of Bernhard S. Schultze, honorary professor of obstetrics and gynecology at the University of Jena, aged 91. He published his paper on the swinging method of artificial respiration for the newly born in 1866.

CORRECTION

Sterility of Catgut.—In the article on this subject published in The Journal, June 14, page 1736, the names of the authors should be C. T. Butterfield and Leo F. Ey.

MEXICO LETTER

Mexico City, Mexico, June 8, 1919.

Association of Medical Students

The medical students have formed an association to work for the intellectual, moral and physical progress of the whole class. The inauguration of the society took place with ceremonies, at which the president of the university and the dean of the school of medicine presided. At the same meeting, honorary diplomas were distributed among the medical students who had obtained them during the school year of 1917.

The Army Medical Board

By direction of the army and navy departments there has been organized a commission composed of army physicians of different rank, for the purpose of studying and proposing reforms that may be necessary in the sanitary service of the army. Dr. J. J. Sánchez, former professor of anatomy in the school of medicine, is the president of this commission.

The Study of Typhus

The University of Harvard has informed the University of Mexico, that provided the required facilities are available, Dr. S. B. Wolbach, professor of bacteriology at Harvard, will come to this country in the near future to make a study on the etiology of the tabardillo (typhus). President Macías answered by telegram that Dr. Wolbach will be most welcome, that all possible aid will be given to him, and that his trip is timely, as there are various questions relating to typhus remaining unsolved, as can be seen from the papers presented at the congress on this disease held here last January. It may be well to remember that about ten years ago, Dr. H. T. Ricketts came to Mexico for purposes similar to those of the Harvard bacteriologist, which unfortunately he could not carry out because of his having contracted the disease and died shortly afterward. Mexico has not been ungrateful towards this martyr of science: one of the laboratories of the *Instituto Bacteriologico Nacional* has in a prominent place on its walls the portrait and the name of this American physician as a tribute to his memory.

Generous Legacy

Information has just been received by the government that Sr. Alberto Parres, who died in Paris and was believed to have left no will, bequeathed $3,000,000 to private benevolent institutions. Sr. Parres was on a pleasure trip in Europe when he died.

Public Poisoning

It has been ascertained that in the city of Saltillo some unscrupulous persons were making bread and pastry dyed with chromate of lead instead of yolks of eggs; other manufacturers were coloring their products with saffron. The first have been prosecuted as poisoners, while the latter will be just fined.

Interest in the English Language

It is remarkable the increasing interest in the English language in Mexico. Three of the newspapers with the largest circulation are written in both Spanish and English; another one in French and English.

BUENOS AIRES LETTER

Buenos Aires, May 5, 1919.

New Outbreak of Influenza

In one of the concentration zones for navy recruits located in the harbor of this capital and very near the Immigration Barracks, there has been observed during the last months an outbreak of influenza of short duration but rather serious, for in some days there were more than 200 cases and six deaths. When the concentration of the naval recruits took place, several outbreaks of influenza occurred in different military zones, especially in the province of Entre Ríos, but they are now on the decline and the mortality has always been very low. In different places (Santiago del Estero, Corrientes, Goya, La Banda, etc.) there have been outbreaks which, while affecting a large portion of the inhabitants, have never assumed much seriousness.

Anthrax

For the last two or three years there has been a notable increase of anthrax in rural sections all over the country. Several official and private organizations have advised the compulsory antianthracic vaccination for animals. At present vaccination is voluntary on the part of the owners. There has also been recommended the appointment of an official controller of vaccination, and a commission studied the matter but without reaching definite conclusions.

Bubonic Plague

After the disappearance of the outbreak of bubonic plague at Salta and Jujuy there have occurred some cases at the railway station at Los Cisnes of the province of Córdoba and also on one of the railway lines that have terminals at the port of Buenos Aires, but both outbreaks have now ceased.

Entrance Examinations to the School of Medicine

The School of Medicine has so many first year students (800) that some measures were needed to limit this excessive number as neither the buildings nor the teaching equipment was sufficient. The staff deemed it, therefore, necessary to require an entrance examination that would permit a selection of the best applicants and decrease somewhat the number of the students. It is authorized to that effect by the law of organization of national universities, but the new students thought they could obtain the revocation of the measure by going on a strike. The board of directors of the School of Medicine would not change its attitude, which received the unanimous support of the students. The movement of the new applicants therefore failed and the entrance examinations remained in force. The dean of the school, Dr. Julio Méndez, who was elected by the students themselves, disapproving of the entrance examinations, when he saw that the students were supporting the board of directors, presented his resignation which was accepted. New elections will therefore be held in the near future to fill the positions of dean and also of a director.

University Appointments

There have been appointed the following professors: Of surgical clinics, Dr. J. Arce; of gynecology, Dr. J. F. Molinari; of pediatrics, M. Acuña; of anatomy, Dr. C. Jakob; of organic chemistry (pharmaceutical), Dr. P. J. Mesigos. Dr. Arce, in his opening address, stated that it is the intention to establish a complete institute of surgical clinics with a research laboratory, etc. In accordance with the new regulations, a number of the substitute professors have commenced to give complete courses which the school considers as valid as those given by the regular professors. A number of other professors have also been authorized to give *cursos libres* (optional courses).

Death of Dr. Penna

Dr. José Penna, the leader in most of the work done in this country against infectious diseases and in charge of the most important sanitary campaigns, and professor of infectious diseases in the School of Medicine, has died suddenly. For nearly forty years no important work was done in public health without his cooperation. He directed and organized the Department of Public Assistance of Buenos Aires and the National Department of Public Health, in which he carried to a satisfactory conclusion the organization of the Bacteriological Laboratory commenced by Dr. Malbrán. Professor Penna published a number of articles on clinical medicine and had an exceptional experience in the diagnosis of infectious diseases.

LONDON LETTER

London, May 28, 1919.

Vital Statistics

Although a considerable decline is recorded in the rate of the mortality in England and Wales during the first three months of this year, as compared with the last quarter of 1918, deaths again exceeded births, the natural decrease of population being 47,002, against 79,443 in October, November and December. The birth rate was unprecedentedly low, representing an annual rate of only 15.6 per thousand of the population. Influenza was either a primary or a contributory cause of death in no fewer than 37,697, or nearly 20 per cent., of the total deaths registered last quarter. Infant mortality, measured by the proportion of deaths under 1 year of age to registered births, was equal to 149 per thousand, being 31 per thousand above the average in the corresponding period of the last ten years.

Smallpox in England and Wales

The danger of the introduction of smallpox into this country by soldiers returning from abroad, which has been apprehended, has been realized. About 100 cases have occurred in England and Wales, including about a dozen in London. The infected soldiers passed through demobilization camps while incubating the disease, and generally the first symptoms were manifested on reaching their homes. On account of the modification produced by infantile vaccination, the nature of the disease was not recognized until it spread to others, especially to unvaccinated persons (of whom, as shown in previous letters, there are large numbers in this country in consequence of the neglect of vaccination). In some cases the disease was introduced by sailors and other persons returning from Portugal, where it is prevalent.

Defective Training of Physicians in Ophthalmology

A report on the teaching and examination of medical students in ophthalmology, issued by the Council of British Ophthalmologists, emphasizes the need of adequate training, particularly in view of the unfavorable position held by Great Britain compared with France, Switzerland, Spain, the United States and many other countries. An analysis of the existing regulations concerning the teaching and examination in ophthalmology in the United Kingdom and abroad shows that Great Britain stands almost alone in granting diplomas to practice medicine without evidence of an adequate knowl- edge of diseases of the eye. There are still three examin- ing bodies that have not even adopted the recommendation of the General Medical Council of 1891 which requires a certificate of attendance at a three months' clinical course. Moreover, at other institutions the interpretation of what is meant by a three months' course varies greatly and should be more accurately defined, as it is by all the American universities. In Great Britain only a small minority of the licensing bodies apply regularly a test of ophthalmic knowl- edge. In Ireland and in the great majority of foreign uni- versities, ophthalmology is one of the subjects of the qualifying examinations, and the examiners are invariably ophthalmic surgeons. The knowledge of ophthalmology possessed by the majority of medical students in Great Britain at the time of their qualification is inadequate to enable them to diagnose and treat efficiently cases of ordinary eye diseases encountered in general practice. The council holds that it is desirable that the training in ophthalmology should be mainly clinical, and agrees that a period of three months is all that can be allotted to the subject in a five years' curriculum. The council recommends, therefore, (1) that attendance at an ophthalmic clinic for not less than six hours a week during a period of three months shall be required of every student, and (2) that such a period of clinical training shall be supplemented by a course of systematic lecture or clinical classes. A serious defect is the absence of any test of the student's knowledge of ophthalmology in the qualifying examinations. Teachers in the medical schools are well aware that without the stimulus of an examination, many students give the least possible attention to ophthalmology and may, and often do, finish their training without gaining even a rudimentary knowledge of the subject. In the opinion of the council, it is most desirable that an examination in ophthalmology should be made an integral part of the qualifying examination by all those licensing bodies that have not heretofore included it in their schedule.

The council recommends that: (1) No student shall be admitted to the final examination qualifying to practice in medicine, unless he has attended an ophthalmic clinic for not less than six hours a week during a period of three months and has attended a course of systematic instruction in ophthalmology, and (2) no student shall be considered to have passed the qualifying examination unless he has shown a sound knowledge of practical ophthalmology in an examination conducted by ophthalmic surgeons.

CUBA LETTER

Havana, May 27, 1919.

New Hospitals and Asylums

The Department of Charities has dedicated a new building in the town of Guanabacoa destined to give shelter to the aged and destitute.

The Grand Masonic Lodge of Cuba will also soon open an asylum for old people called "La Misericordia." The corner stone of the last building of this institution was laid May 20, Cuban Independence Day.

Güines, a town of about 25,000, in the province of Havana, is building a new hospital to cost $100,000.

The Association of the natives of the Canary Islands has purchased the site for their hospital. It will have a beautiful location on the road from Havana to Bejucal.

Plans for Better Dwellings

The old *bohio*, the traditional country dwelling of the Cuban peasant, will, for sanitary and hygienic reasons, soon be a thing of the past. The *bohio* is a small frame dwelling built level with the ground and has a roof of palm leaves and a dirt floor. It has no sanitary conveniences whatever, and usually consists of only one room, in which the family lives, sleeps, cooks and—dances. The Board of Health of the Republic has invited architects to present plans and estimates for the construction of comfortable and sanitary dwellings for the country population, and has offered a prize of $500 for the best plans.

Personal

Drs. Orosman Lopez, Y. Clark and C. Yarini have been appointed professors at the Dental School, University of Havana. Dr. J. A. Hernandez Ybañez has been appointed assistant in physiology at the University of Havana Medical School.

Requisites for Acceptance of Foreign Diplomas by the Cuban Authorities

Heretofore any physician in possession of a medical diploma has been permitted to practice in the Republic of Cuba after passing an examination and paying the appointed fees. A bill just passed by the House of Representatives will impose certain restrictions and conditions on foreign medical graduates. They will have to prove the authenticity of their diplomas, since counterfeits have been quite com- mon. They must also pass an examination in every subject of the curriculum of the medical school. There are thus nearly thirty different subjects in which the applicant must pass. Failure in any one of them deprives him of any further trials.

Marriages

Alford Edwards Budde, Capt., M. C., U. S. Army, North Chicago, Ill., on duty in London, England, to Miss Madeleine de Colnet d'Huart of Bayswater, London, April 16.

Herbert L. Wilbur, Capt., M. C., U. S. Army, Granby, Mo., to Miss Cora B. Scott of Washington, Ind., June 8.

Lesley Tracy Gager, Stonington, Conn., to Miss Josephine Willoughby Chapman of Towson, Md., June 15.

Edward Montgomery Duncan, Govans, Md., to Miss Clara May Owens of Norwalk, Conn., June 2.

Frank Thomas Fort, Louisville, Ky., to Miss Elizabeth Odele Brown, at Baltimore, June 4.

Frank W. Morley to Miss Florence Sneider, both of Toledo, Ohio, May 27.

Elmer Leonard Mertz to Miss Hazel L. Cooper, both of Rockford, Ill., June 7.

Deaths

Victor Clarence Vaughan, Jr. ⊕ **Major, M. C., U. S. Army,** Detroit; University of Michigan, Ann Arbor, 1902; aged 39; on duty with the American Expeditionary Forces in France; was accidently drowned in France, June 10. Major Vaughan was associate professor of preventive medicine and assistant professor of medicine in the Detroit College of Medicine and Surgery; a specialist in internal medicine, at one time was health officer of Detroit, and was a member of the American Association of Pathology and Bacteriology.

Edward Kent Armstrong ⊕ Chicago; Dearborn Medical College, Chicago, 1904; University of Illinois, Chicago, 1905; Northwestern University Medical School, Chicago, 1910; aged 38; a specialist in pediatrics; superintendent of the Municipal Contagious Disease Hospital of Cook County, 1917; who had served in France since April, 1918, and was later assigned to duty in Palestine where he was engaged in repatriation work; is reported to have been killed recently in an automobile accident.

Lewis Merritt Palmer ⊕ Framingham, Mass.; Harvard Medical School, 1881; aged 68; a specialist on diseases of the ear, nose and throat; medical examiner (coroner) for the eighth Middlesex district since 1902; surgeon to the Framingham Hospital, and the Reformatory for Women; trustee of the Massachusetts Training School, and treasurer of the Massachusetts Medico-Legal Society; died at his home, June 4, from angina pectoris.

Warren Schoonover ⊕ New York City; College of Physicians and Surgeons in the City of New York, 1867; aged 81; house physician, secretary and a member of the board of managers of the Northeastern Dispensary since 1873; a member of the American Academy of Medicine and American Public Health Association; died in the Broad Street Hospital, New York City, June 3, after an operation for the removal of an abdominal growth.

Mgrditch Simbad Gabriel ⊕ New York City; Central Turkey Medical College, Aintab, 1881; aged 62; professor of practice of medicine in his alma mater in 1885 and 1886; since that date a practitioner of New York City; president of the Armenian General Progressive Asociation; author of several works on Armenia; editor of an Armenian magazine; died in the North Hudson Hospital, Weehawken, N. J., June 3.

Edward E. Lindeman ⊕ New York City; Johns Hopkins University, Baltimore, 1908; aged 39; formerly acting assistant surgeon, U. S. P. H. and M. H. Service; a fellow of the New York Academy of Medicine; an authority on the transfusion of blood; who was in attendance at the meeting of the American Medical Association in Atlantic City; was accidentally drowned, June 12, while bathing.

Caroline V. Wiley Anderson, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1878; aged 70; one of the foremost negro physicians of Philadelphia; for many years in charge of the medical department of the twenty-ninth ward and vice president of the Berean Manuel Training School; died at her home, June 3, from cerebral hemorrhage.

Adolph Brand, New York City; College of Physicians and Surgeons in the City of New York, 1904; aged 40; a specialist in dermatology; a member of the American Urological Society and New York Academy of Medicine; dermatologist to the Hospital for Deformities and Joint Diseases; chief dermatologist to St. Bartholomew's Clinic, and assistant dermatologist to Bellevue Hospital; died at his home, June 2.

Arthur Howard McCray, Lieut., U. S. N. R. F., Helena, Mont.; George Washington University, Washington, D. C., 1915; aged 38; state bacteriologist of Montana; who contracted Rocky Mountain spotted fever from an inoculated guinea-pig, June 5; died in a hospital in Helena, June 15, from the disease.

Philander S. Root ⊕ Monroe, Mich.; Detroit Medical College, 1881; aged 63; president of the Monroe County Medical Society in 1913, and secretary in 1917; local surgeon of the Lake Shore and Michigan Southern Railroad; also a banker and newspaper publisher; died at his home, June 6, from heart disease.

Denman Rathbun Kinsell, Jr., Columbus, Ohio; Ohio Medical University, Columbus, 1898; aged 57; a member of the Ohio State Medical Association; a member of the associate staff of the Lawrence Hospital, Columbus, and of the American Electro-Therapeutic Association; died at his home, June 3.

William Elzie Terry, Long Beach, Miss.; Kentucky School of Medicine, Louisville, 1897; aged 49; a member of the Mississippi State Medical Association; while returning from a professional call and driving over a grade crossing near Long Beach, May 15, was struck by a train and instantly killed.

Clarence F. Barker, Okenama, Mich., formerly of Chicago; Hahnemann Medical College, Chicago, 1880; aged 67; for twenty years professor of surgery in his alma mater; died in Milwaukee, June 7, from shock following the amputation of a leg, on account of diabetic gangrene.

Henry Clay Day, Bennington, Vt.; College of Physicians and Surgeons in the City of New York, 1870; aged 74; for twenty-five years a druggist of Bennington; a member of the village board of trustees, and school trustee; died at his home, May 26, from acute gastritis.

Oscar Fitzallan Swasey, Beverley, Mass.; Bowdoin Medical School, Brunswick and Portland, Me., 1853; aged 92; a member of the Massachusetts Medical Society; for several years town physician and a member of the staff of Beverly Hospital; died at his home, June 4.

Samuel Smith Shields, Carbondale, Pa.; Medical College of Georgia, Augusta, 1873; aged 71; for many years chief of staff of the Carbondale Emergency Hospital; a fellow of the American Academy of Railway Surgeons; died at his home, May 30, from heart disease.

Elisha D. Beard, Brownsburg, Ind.; Medical College of Indiana, Indianapolis, 1893; aged 52; for fifteen years a practitioner of Indianapolis; while driving his car over a grade crossing near Avon, Ind., May 1, was struck by a fast train and instantly killed.

William M. Floyd ⊕ Henderson, Ky.; University of Louisville, Ky., 1891; aged 52; a specialist on diseases of the eye, ear, nose and throat; once president of the Henderson County Medical Society; died at his home, May 17, after an operation for appendicitis.

Freeman Dodd Bosworth, Coolidge Corner, Mass.; Harvard Medical School, 1906; aged 43; examining physician for the Boston Society for the Care of Girls; one of the founders of Lancaster Hospital, Brookline; died in that institution, June 2.

John G. Brennen, New York City; College of Physicians and Surgeons, Baltimore, 1914; aged 33; a graduate of Columbia University College of Pharmacy in 1905; died in the Manhattan State Hospital, May 16, from general paralysis.

Frederick Kendall Brown ⊕ Philadelphia; Jefferson Medical College, 1890; Medico-Chirurgical College of Philadelphia, 1896; aged 54; assistant ophthalmologist to the Pennsylvania Hospital Dispensary; died at his home, May 31.

Thomas H. Monahan, Salt Lake City; Minneapolis College of Physicians and Surgeons, 1886; aged 51; formerly in charge of the Northern Minnesota Hospital, Crosby; died at his home, recently, from cerebral hemorrhage.

William Parker Mercer, Elm City, N. C.; New York University, New York City, 1879; aged 64; for two terms state senator from Edgecomb County; died at his home, May 28.

⊕ Indicates "Fellow" of the American Medical Association.

William Hoyt, Hillsboro, Ohio; Cleveland University of Medicine and Surgery, 1867; aged 79; a veteran of the Civil War; medical director of the Department of Ohio, G. A. R., in 1903; died at his home, May 31.

William E. Courson, Beulah, Miss.; Southern Medical College, Atlanta, Ga., 1884; aged 55; a practitioner since 1882; who went to California about six months ago for his health; died in Alhambra, Calif., May 22.

J. O. Wharton, Waverly, Ind.; Indiana Medical College, Indianapolis, 1877; aged 67; died in Martinsville, Ind., April 13, from injuries to the chest received in an automobile accident five months before.

Woods Frederick Derr ⊕ Williamsport, Pa.; Johns Hopkins University, Baltimore, 1915; aged 29; a specialist in surgery; died at the home of his parents in Watsontown, Pa., May 27, from tuberculosis.

John Henry Thompson, New York City; New York Medical College, New York City, 1853; aged 84; surgeon of U. S. Volunteers during the Civil War; died at his home, June 7, from arteriosclerosis.

Michael J. Griffith, Washington, D. C.; Georgetown University, Washington, 1869; aged 79; a veteran of the Civil War; deputy registrar of wills for forty-three years; died at his home, May 25.

Charles Biddle Bush ⊕ Philadelphia; Jefferson Medical College, 1885; aged 59; a specialist on diseases of the eye, ear, nose and throat; died in the Orthopedic Hospital, Philadelphia, May 27.

Henry C. Dimond, Philadelphia; University of Pennsylvania, Philadelphia, 1881; aged 63; formerly secretary of the Clark County (Ohio) Medical Society; died at his home, January 4.

Edward B. Schwartz, Buffalo; University of Buffalo, N. Y., 1881; aged 52; consultant to the City Hospital for Women, Buffalo; a musician and linguist of talent; died at his home, May 23.

William Herbert Beazley, Sheppard, Texas; New Orleans School of Medicine, 1867; aged 81; a member of the State Medical Association of Texas; died at his home, May 18.

Charles P. King, Newark, Ohio; Jefferson Medical College, 1867; aged 78; died at St. Anthony's Hospital, Columbus, Ohio, May 28, from cerebral hemorrhage.

George Robert Spooner, Worcester, Mass.; Hahnemann Medical College, Philadelphia, 1870; aged 72; a veteran of the Civil War; died at his home, May 24.

Jacob C. Knowles, Seaford, Del.; College of Physicians and Surgeons, Baltimore, 1897; aged 53; died at his home, May 23, from carcinoma of the liver.

James Calvin Stem, Goldsboro, Pa.; Cincinnati College of Medicine and Surgery, 1878; aged 64; died in York, Pa., May 18, from cerebral hemorrhage.

Thomas Benton Brooks, Lynch, Ky.; Kentucky University, Louisville, 1903; aged 49; died at the home of his wife's parents in Valley, Ky., May 20.

John C. Dalton, Pasadena, Calif.; Starling Medical College, Columbus, Ohio, 1874; aged 69; died at his home, May 19, from arteriosclerosis.

Stephen L. Strickler, Boggstown, Ind.; Eclectic Medical Institute, Cincinnati, 1879; aged 65; died at his home, May 23, from cerebral hemorrhage.

Solomon Lewin, Chicago; Ensworth Medical College, St. Joseph, Mo., 1892; aged 62; died in Los Angeles, May 24, from aneurysm of the aorta.

Clarence C. Bullard, Opelika, Ala.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1891; aged 55; died at his home, June 1.

Charles E. Angell, Delphi, Ind.; Jefferson Medical College, 1880; aged 68; died at his home, May 15, from cerebral hemorrhage.

Bertha Emma Zahn, Bascom, Ohio; Ohio Medical University, Columbus, 1898; aged 48; died at her home, about May 24.

Joseph B. Eversole, Adeline, Ill.; Rush Medical College, 1866; aged 86; died at the Ogle County Home, Ore., May 24.

J. Allen Harrison, Philadelphia; Hahnemann Medical College, 1892; aged 46; died at his home, May 25, from influenza.

Perry C. Johnson, Lakeland, Fla.; Eclectic Medical Institute, Cincinnati, 1889; died recently at his home.

Edward D. Hope, Macon, Ga.; Atlanta (Ga.) Medical College, 1891; aged 58; died at his home, May 18.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

MORE MISBRANDED NOSTRUMS

Samaritan Nervine.—Shipped about January, 1913, by the Dr. S. A. Richmond Nervine Co., St. Joseph, Mo. Analysis showed the preparation to contain nearly 19 per cent. of potassium bromid, with indications of atropin. Falsely and fraudulently represented as a specific for epilepsy, seminal weakness, every form of kidney disorder, pulmonary affections, rheumatism, gout and heart disease, and as a cure for scrofula, syphilis, loss of hearing and paralysis. Fine, $45 and costs, imposed Sept. 18, 1917.—[*Notice of Judgment No. 6309; issued May 10, 1919.*]

Phenol Sodique.[1]—Shipped about July, 1915, by Hance Bros. & White, Philadelphia. Falsely and misleadingly claimed to be non-poisonous, when in fact it contained phenol (carbolic acid), and to be effective as a disinfectant when used according to directions, when as a matter of fact placing the product in shallow vessels or sprinkling a solution of it about the apartment would not disinfect impure and unhealthy localities or prevent the spread of yellow fever, typhoid fever, scarlet fever, cholera, etc. It was declared misbranded also, in that it contained no ingredients or combination of ingredients which would cure catarrh, erysipelas, piles, sprains, ulcers and various other ailments mentioned in or on the trade package. In June, 1918, Hance Bros. & White consented to a decree, and judgment of condemnation and forfeiture was entered. On the order of the court the product was delivered to the company on the payment of the costs and execution of a bond.—[*Notice of Judgment No. 6313; issued May 10, 1919.*]

Nuxcara.—Shipped about April, 1916, by Reuben B. Kelley, president of the Nuxcara Mfg. Co., Atlanta, Ga. Analysis showed the product to contain over 11 per cent. of alcohol, together with cascara, strychnin and berberin, and small quantities of other vegetable material. Falsely and fraudulently represented as a positive remedy for indigestion, dyspepsia, catarrh, bronchitis, rheumatism, neuralgia, etc., and as a cure for kidney and liver trouble, chronic appendicitis, etc. Fine, $25, imposed November, 1918.—[*Notice of Judgment No. 6340; issued May 10, 1919.*]

Dr. A. Upham's Valuable Electuary.—Shipped about October, 1916, by John Green Hall and Augustus Steele Hall, copartners, trading as J. G. & A. S. Hall, Oxford, N. C. Analysis showed the preparation to be a tablet composed essentially of cream of tartar, potassium nitrate, resins, sugar, sulphur, gum and vegetable extractives. Falsely and fraudulently represented as an infallible remedy for internal, external, blind and bleeding piles, and as a remedy for all affections of the bowels, liver complaint, dyspepsia, etc. It was also fraudulently represented as a remedy for paralysis, apoplexy and measles, and as a cure for tumors, inflammation of the stomach, kidneys, etc. Fine, $100 and costs, imposed June, 1918.—[*Notice of Judgment No. 6349; issued May 10, 1919.*]

Malaria.—Malaria is derived from two Italian words, *Mal* and *Aria,* which mean bad air. The record of malaria reaches back to Hippocrates, who lived 400 years before Christ. Hippocrates divides the disease into the "every-day chills" and the "every-other-day chills."—*Malaria Circular,* North Carolina Board of Health.

---

[1] A report of the Council of Pharmacy and Chemistry on "Phenol Sodique" was published in this department of THE JOURNAL, Nov. 9, 1907. The Council declared that the claims made at that time for Phenol Sodique were "unscrupulous" and "a positive menace to the public health."

Correspondence

"THE GOLDENROD AND 'HAY-FEVER'"

To the Editor:—I have read with approval and interest the defense of goldenrod as a cause of hay-fever in The Journal, May 31, by my distinguished confrère, Dr. John Noland Mackenzie of Johns Hopkins University.

As an old practitioner of otolaryngology I have seen the various nostrum serums, infusions, etc., "have their day and cease to be," and have noted "how fast does system follow system from sunlight to the sunless land."

It was in 1891 that I first developed well-marked hay-fever, while on a visit to Manitou Springs, Colo., of more than 6,500 feet elevation, at the foot of Pike's Peak, where the commonly believed pollens of hay-fever are not found. I was then practicing medicine in Kansas City, and up to that time had only a supersensitive schneiderian membrane, sneezing frequently, under varying conditions of slight nasal irritation, changes from heat to cold, sunlight, etc. I spent several weeks in Manitou, afflicted with typical nasal hay-fever, and went on to California and up to British Columbia, remaining about two weeks, during which time all symptoms disappeared. But I had no sooner come into the high lands of Wyoming on my way home, when all the old symptoms returned, and they continued annually ever since from mid August to near October 1, though through all the year I am as of old more or less subject to sneezing on slight provocation. During my "season" I dare not use any applications, for even the mildest and most "soothing" seem to set up irritation. Menthol has always been very irritating. During the year 1893 I was in London, engaged in the study of my specialty, and returned to America, September 1, landing at New York. I had no symptoms until I reached Washington, D. C., a few days later.

About five years ago I spent the summer, until September 1, on the Mississippi Sound at Pass Christian. I started to St. Louis the last day of August, and felt no distress until I arrived in Memphis next day. During the summer of 1918 I was major chief of the Head Section of Base Hospital, Camp Beauregard, La. This camp is in the center of the state, 192 miles northwest of New Orleans. The Red River cuts across the county in which the camp was located, from East to West, and marks sharply the north line of the sugar belt. North of the river are high hills clad with pines, oaks and most of the indigenous trees of the South or Central states. Below the river the topography is as different as if one were in two different countries. There we had vast flat lands covered with cotton, cane, corn, with swamp forests and low lands adjacent. There is no flora growing in and around St. Louis that does not flourish in this section; and, as might be imagined, there are many varieties that are not found in the uniformly high lands around St. Louis; yet I had not even a sniff of hay-fever during my incumbency at this camp.

About fifteen years ago, Dunbar, whose serum nostrum has had so much advertising and patronage with the profession, visited St. Louis. The otolaryngologists were celebrating him, for his star was at that time in the ascendent. No one cared to say anything critical of the distinguished professor. Among his adulators was an otolaryngologist of St. Louis, well known throughout America. It was then late August in the midst of the hay-fever season. At the special meeting of the local society, which Dunbar addressed, this otolaryngologist hazarded the statement that he was then treating twenty cases of hay-fever with Dunbar's serum, with complete or partial relief to nineteen. I do not quote this as intending to be critical, but I have often felt an amused desire to ask how many cases he is curing now. Having a suburban home, it happened that the day of this meeting I had some high blue-grass pasturage cut, the grass, of course, being mixed with goldenrod, ragweed and all the rest of the indicted flora. I wanted to present myself before Dunbar as a "horrible example," so I went out and wallowed in the new mown hay, then plucked a fresh sprig of "the bride of the autumn sun," and none the worse, presented myself at the meeting and told Dunbar and his adulators that his remedy was based on assumption and empiricism.

Dr. Mackenzie well says that "the true character of this remarkable disorder is still elusive, baffling and far off. Through the uncertain and changing atmosphere which surrounds it we as yet see dimly." The mystery of this most mysterious disease! Rational, considering men who are not swept from their mental moorings by preconceived desire and ephemeral circumstance, or brow-beaten by inconclusive hypothesis, say to each other, as did the intellectual Iago: "Virtue! a fig! 'tis in ourselves that we are thus or thus"; or as did the far-visioned Hamlet: "There are more things in heaven and earth, Horatio, than are dreamt of in your philosophy."

Fayette C. Ewing, M.D., St. Louis.

COMFORT AND COLD

To the Editor:—It is a never-ceasing source of wonder that certain fundamental principles are so slowly grasped by the human mind. The article of Major Head (The Journal, May 3, 1919, p. 1268) is an admirable example of the misunderstanding of fresh air treatment of pneumonia, and Major Head is particularly to be commended for his frank statement of the case. The results as shown should have been expected, and it is hoped that the conclusions that he draws will be indelibly limned on the minds of the medical profession with the cause accentuated so that such errors may never again be repeated.

Those who have been accustomed to the use of the fresh air treatment of tuberculosis and pneumonia will agree that the fundamental truth to be insisted on is that the patient shall never be uncomfortable; that discomfort is incompatible with rest; that shivering is nature's method of fighting discomfort and raising temperature; that depression is to be avoided at all times; that it is quite possible to be in the cold and yet not be cold; that if the patient is uncomfortable it is due to his not being properly taken care of—that some minor technic has been overlooked by the nurse, and that the nurse is in a majority of cases the one responsible for failure. I myself have found this so much to be the case that I regard the comfort of the nurse, and attention to her clothing, shoes and surroundings as the first things to provide, after which I could expect her to take care of the patient; but if the nurse is uncomfortable I should count on the patient's being neglected.

The requirements are so simple that sufficient stress has not been laid on them. Outdoor treatment has not been carried out in its entirety even in sanatoriums where such treatment should have been familiar. I have known of hospitals where the climate was expected to be cold so constructed and outfitted that cold weather caught them unprepared for just such emergencies.

If patients are properly protected below the mattress as well as above, the pillows properly arranged, proper nightcaps supplied, and bed socks and shields prepared, they can stand almost any climatic change with comfort—their bodies in the climate of Florida while their noses may be in the arctic regions. As Major Head says, "The skins must be red, *not blue; they must be warm, not cold.*" *Only* cold will beat down their fever, stimulate their hearts, and supply them with unprebreathed air. Breathed or exhausted air can produce no more heat than the ashes of coal or wood. Rain, fog and excessive breeze should all be deflected; and as to the windows and doors, that is a matter of orientation and architecture that varies in every case.

The vision of my old, French-Canadian guide rising ruddy and refreshed from his bed of spruce between the heavy logs that he had cut for himself, and shaking off the 3 inches of snow that had fallen in the night, while I could hardly venture from my heated tent, comes before me. He had taken care with the logs on each side and at the head and foot to cut off the entrance of air to his body; while, he being wrapped in his blanket and his cap pulled down, the rising vapor of his breath kept an *open chimney through* the snow to the outer air. Eighty years of life in the open had taught him the value of fresh air.

If there is one principle that was demonstrated by the mass of statistics in the War of the Rebellion, it was that the old campaigner who knew how to take care of himself in a tent withstood his pneumonia better than in the closed ward of the hospital, while the raw recruit who did not know how to keep himself warm suffered.

The architecture of our camp hospitals has improved very much since those days, and the proper ideas of ventilation have been widely accepted.

But bearing in mind the principles outlined above of the absolute comfort of the patient being the essential thing, plus the unprebreathed, undeoxygenated air, much that seems strange in Major Head's statistics would be explained.

J. Clinton Foltz, M.D., Chestnut Hill, Philadelphia.

"SEROLOGIC CURE (?) IN THE LIGHT OF INCREASINGLY SENSITIVE WASSERMANN TESTS"

To the Editor:—In The Journal (May 24, 1919, p. 1526) Wile and Hasley discredit the Wassermann as a therapeutic guide, saying: "As a guide to therapeusis the Wassermann reaction does not have a leg to stand on. We stand today with regard to the treatment and cure of syphilis as did the syphilologists of the pre-Wassermann day." To these statements I cannot subscribe, and I wish to point out wherein Wile and Hasley appear to me to be in error. They have attempted to draw a parallel between the Wassermann reaction and the tuberculin test. This adds nothing to the force of their argument because: First, it has never been proved that in the presence of a positive tuberculin test there are not living tubercle bacilli; and, second, as stated, we do not know the exact mechanism of the Wassermann reaction. We do know, however, that with certain well known exceptions, the Wassermann reaction is diagnostic of syphilis. In other words, we know that, with these exceptions, it never occurs in a person who has not at some time harbored living spirochetes.

Most syphilologists and serologists will admit that the Wassermann test performed with ice-box incubation is more delicate in detecting the "Wassermann bodies," both in untreated and in treated patients. This does not mean *a priori* that because it is more delicate the test is not an indication of living spirochetes, which we know must be present to produce it in the first place. And even Wile and Hasley admit, and show by their statistics, that the Wassermann test as carried out by the ice-box incubation method is sometimes completely negatived by treatment (over 15 per cent. of their cases, as against 50 per cent. by the older method). Furthermore, because the ice-box incubation creates a more delicate test than the water-bath incubation, it does not follow that eventually a technic will be developed which will be so delicate as to detect all persons who have ever had syphilis, regardless of whether or not a cure has been accomplished.

We know that certain of our patients whom formerly, by the older methods of performing the Wassermann test, we considered as probably cured have come back to us in one or more years with positive tests. Wile and Hasley have not shown that cases in which the ice-box Wassermann test was negatived eventually, by treatment, become positive. But even if this does occur, and I think it probable, why should we tell these patients that they are cured, provided, of course, a clinical cure exists, when we have evidence of a positive test which we know never exists without at least a previous active syphilis?

There are certain cases which are "Wassermann fast." The discovery of more of this type of case by the ice-box method is merely an indication that we are getting fewer complete cures than we formerly thought we were, and that these patients should all be treated as syphilitics, receiving courses of treatment periodically throughout their lives.

In so-called primary syphilis the Wassermann test never becomes positive on account of the treatment the patient receives. If treatment will keep a patient from developing a positive Wassermann test which, in untreated cases, is an indication of the presence of living spirochetes, and we assume the syphilis has been cured in such patients, a constantly negative test following treatment of a patient who formerly had a positive test is an indication of cure. It is, in fact, the only indication, except, of course, a clinical cure.

Until it can be shown that a person who has been completely sterilized of spirochetes (and who can prove that this has occurred?) still gives a positive Wassermann, a positive Wassermann test, no matter how delicate, is an indication of the probable presence of living spirochetes, and the patient should be treated on these grounds.

As far as I know, no syphilologist ever relied on a negative Wassermann test alone as a cure for syphilis, but insisted on a clinical cure also, or, perhaps better, insisted on a clinical cure plus a negative Wassermann. Instead of being no better off than the syphilologists of the pre-Wassermann day, we are infinitely better off, particularly since the work of Wile and Hasley has shown us that the Wassermann test performed by the ice-box incubation is more delicate in detecting the "Wassermann bodies" following intensive therapy than were the older methods. In other words, we are going to keep more uncured syphilitics under treatment, or at least under close surveillance than we formerly did.

Loyd Thompson, M.D., Hot Springs, Ark.

PREVENTION OF RELAPSES IN CASES OF ARRESTED TUBERCULOSIS

To the Editor:—Since the publication of my article on the "Prevention of Relapses in Cases of Arrested Tuberculosis Among Soldiers" (The Journal, Feb. 22, 1919, p. 539), I have delivered addresses on this subject on a lecture tour extending from the Atlantic to the Pacific. I received many suggestions and criticisms in the discussions which followed the reading of my paper as well as in letters. I desire to reply to the most important criticism, which is in reference to respiratory exercises.

The thought was expressed by a number that respiratory exercises would stimulate the tuberculous process to greater activity. Another criticism was to the effect that a mistake might be made by the less experienced clinician in declaring a case arrested when in reality it was still active. To these criticisms I would reply that I was not prescribing respiratory exercises for the tuberculous patient, but for the cured individual whose tuberculous process had been arrested. But I failed to point out in my lecture the inestimable advantage to be gained by letting the patient take gradual breathing exercises before allowing him to resume physical labor of any kind. Relapses occur frequently in certain cases in which the physical examination does not reveal any activity and there are no symptoms. The patient is pronounced an arrested case and allowed to leave the sanatorium. Yet he relapses after a few days or a week of physical labor. I believe we have all made mistakes in allowing patients to go to work too soon. But now, instead of telling the patient to go to work as soon as all the active symptoms have quieted down and only the physical signs of an arrested case remain, I start gradual breathing exercises and the patient is examined frequently, so as to determine whether or not an activity is reawakened. After from four to six weeks' preparation by massage, hydrotherapy, and respiratory therapy, when frequent examinations do not reveal any renewed activity, we may be reasonably certain that the disease is sufficiently arrested to allow the patient to resume physical labor with safety.

As long as the patient is on the reclining chair, he breathes but little and very quietly. Any physical exertion or labor will accelerate the respiratory movements, and it would seem unwise to allow his respiratory system to be submitted brusquely to so great a change as is inevitable when the patient begins to do physical labor which cannot be regulated, particularly when he is away from the sanatorium. Even for graded labor, which is of inestimable advantage, the careful preparation by breathing exercises is a valuable and safe procedure, because the patient can begin very slowly while yet on the reclining chair.

S. Adolphus Knopf, M.D., New York.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

REQUIREMENT AS TO HOSPITAL RECORD UNDER HARRISON LAW

To the Editor —Please render an opinion on the following matter: A and B are regularly licensed physicians patronizing the same hospital. A contends that each time he instructs a nurse to give a hospital patient a hypodermic injection of morphin, or any other drug coming under the Harrison Narcotic Act, he should leave not only a written and signed order but should place after his signature his registration number. B says that it is unnecessary to add the registration number to the signature each time.

W. B. T., Texas.

Answer.—According to Internal Revenue Regulations No. 35, regarding hospital records, "No special form of record is required, but it (the record) must enable an inspecting officer to quickly ascertain the quantity and kind of narcotic drugs used and show the names and addresses of patients to whom administered and indicate the authority for such administration. The initials of a physician giving directions for the administration of a narcotic should appear on the chart of the patient, or separate prescriptions should be required by the pharmacist in charge of the drug room before the narcotics leave his possession." From this ruling it would appear that it is optional with hospitals whether they require each order for hypodermics to be initialed by the physician or separate prescriptions to be written for file in the drug room. If the first plan is followed, the initials of the physician are sufficient. His full signature and registration number are not necessary. If the second plan is followed, then the prescriptions must show the name and address of the patient, the date and name and address of the physician, and his registry number.

DECORATIONS THAT MAY BE WORN BY THOSE ENGAGED IN THE PRESENT WAR

To the Editor:—With the exception of medals bestowed for acts of bravery, there seems to be a lack of information on the subject of medals, buttons, bars, etc. Will you please publish a list of decorations that overseas men are entitled to have and to wear; also a list of the decorations to which discharged soldiers who did not go overseas are entitled? How are such victory medals, service medals, bars, etc., procured—by purchase or as a gift from the government?

L. A. Denis, M.D., West Hoboken, N. J.

Answer.—G. O. No. 48, War Department, April 9, 1919, is all that has been published on the subject of medals and ribbons for the present war. This order provides that a war service medal, to be known as the Victory Medal, will be awarded to all officers and enlisted men who served on active duty in the Army of the United States at any time between April 6, 1917, and Nov. 11, 1918, and whose service was honorable. Battle clasps will be awarded to officers or enlisted men who have actually participated under orders in the following engagements: (*a*) Somme, defensive, between March 21 and April 6, 1918. (*b*) Lys, between April 9 and April 27, 1918. (*c*) Aisne, on the Chemin des Dames and northeast of Rheims between May 27 and June 5, 1918. (*d*) Montdidier-Noyon, between June 9 and June 15, 1918. (*e*) Champagne-Marne, between July 15 and July 18, 1918. (*f*) Aisne-Marne, between July 18 and Aug. 6, 1918. (*g*) Somme, offensive, between Aug. 8, and Nov. 11, 1918. (*h*) Oise-Aisne, between Aug. 18 and Nov. 11, 1918. (*i*) Ypres-Lys, between Aug. 19 and Nov. 11, 1918. (*j*) St. Mihiel, between Sept. 12 and Sept. 16, 1918. (*k*) Meuse-Argonne, between Sept. 20 and Nov. 11, 1918. (*l*) Vittorio-Veneto, between Oct. 24 and Nov. 4, 1918.

Clasps will be awarded to each officer and enlisted man who served overseas and is not entitled to a battle clasp under paragraph 2, for service in France between April 6, 1917, and Nov. 11, 1918; for service in Italy between April 6, 1917, and Nov. 11, 1918; for any service in Siberia; for any service in European Russia, and for service in England between April 6, 1917, and Nov. 11, 1918.

A bronze star, three-sixteenths inch in diameter, will be placed on the service ribbon for each battle clasp awarded. When an officer or enlisted man has been cited in orders issued from the headquarters of a force commanded by a general officer for gallantry in action not justifying the award of a medal of honor, distinguished-service cross, or distinguished-service medal, he will wear a silver star for each such citation.

Pending the procurement and issue of the Victory Medal, organization commanders are authorized to permit those serving under them to wear the service ribbon and stars to which they are entitled as shown by their records.

The War Department has also issued a circular concerning victory buttons. A lapel button to be known as the Victory Button, for wear on civilian clothes, will be issued to all officers, enlisted men, field clerks and members of the Army Nurse Corps who served honorably on active duty in the Army of the United States for a period of fifteen days at any time between April 6, 1917, and Nov. 11, 1918. The button will be of silver for those wounded in action and bronze for all others.

The various medals, battle clasps, bronze stars, ribbons and Victory Buttons mentioned are not as yet ready for issue and will not be for some time, nor have instructions been issued as to how such decorations are to be distributed when available. When the decorations are ready for issue and instructions regarding such issue have been promulgated, the matter will be given wide publicity in the press.

PRESCRIBING ALCOHOL—PAREGORIC NOT INCLUDED UNDER NARCOTIC ACT

To the Editor —1. Is there a new law preventing a physician from prescribing absolute alcohol for medical purposes? 2. Is it necessary to put a registry number on a prescription containing camphorated tincture of opium?

F. E. Dostal, M.D., Chicago.

Answer.—1. No. 2. No.

"INTERCOSTAL PAIN FOLLOWING HERPES ZOSTER"

To the Editor —The question asked by J. W. W. regarding the treatment for severe intercostal pain following herpes zoster (The Journal, May 31, 1919, p. 1635) leads me to write of the experience I had with this condition four years ago. A woman suffered from this condition for a period of four or five months. She was more than 70 years old, and all remedies used were of no avail. She was constantly kept under the influence of opiates. Examination revealed no signs of cord lesion. It occurred to me that injection of alcohol into the region of the posterior root ganglion might be tried. This was done. For nearly twenty-four hours the pain was intensified, and then suddenly disappeared, the patient remaining well until about three years ago, when she died.

This method, if carefully done, is probably without any particular danger. The plexus surrounds this ganglion, and the aim should be, as happened in this case, to strike this plexus, drawing back on the piston of the syringe and obtaining blood. This shows that the region of the ganglion has been reached. The needle is withdrawn slightly and the injection made. I used in this particular case 2 c.c. of 80 per cent. alcohol. In such a painful condition this treatment might be worth trying before surgical methods are resorted to.

S. R. Salzman, M.D., Toledo, Ohio.

A Lesson of the War.—We all hope that we are done with war and with soldiers, at least for a generation. We can, however, derive certain broad lessons applicable to the conditions of peace from the experiences and intense activities of war, when almost unlimited funds were obtainable for research and the experiences ordinarily scattered over years were crowded into a few months. One of these lessons is that scientific men need to develop the capacity to become heads of large enterprises without ceasing to be scientific, without degenerating, as is too often the case, into the superclerk, who seems to be the American ideal of the high executive official. It is not enough for the scientific man to become the expert adviser to the unscientific administrator. If the latter has the *responsibility* he will use his power as he and not as the scientific man sees fit.—Yandell Henderson, *Science,* May 9, 1919.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Alabama: Montgomery, July 8. Chairman, Dr. S. W. Welch, State Capitol, Montgomery.

Arizona: Phoenix, July 1. Sec., Dr. Allen H. Williams, 219 Goodrich Bldg., Phoenix.

California: San Francisco, June 23-26. Sec., Dr. Charles B. Pinkham, 904 Forum Bldg., Sacramento.

Colorado: Denver, July 2. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

Connecticut: New Haven, July 8-9. Sec., Regular Bd., Dr. Charles A. Tuttle, 196 York St., New Haven; Sec., Homeopathic Bd., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven; Sec., Eclectic Bd., Dr. James E. Hair, 730 State St., Bridgeport.

District of Columbia: Washington, July 8-10. Sec., Dr. E. P. Copeland, The Rockingham, Washington.

Kentucky: Louisville, July 1-3. Sec., Dr. J. N. McCormack, Bowling Green.

Louisiana: New Orleans, July 1-3. Sec., Dr. E. W. Mahler, 141 Elk Place, New Orleans.

Maine: Augusta, July 1-2. Sec., Dr. Frank W. Searle, 776 Congress St., Portland.

Massachusetts: Boston, July 8-10. Sec., Dr. Walter P. Bowers, State House, Boston.

Mississippi: Jackson, June 24-25. Sec., Dr. W. S. Leathers, University.

Nebraska: Lincoln, June 30-July 2. Sec., Dr. H. J. Lehnhoff, 514 First National Bank, Lincoln.

New Mexico: Santa Fe, July 14. Sec., Dr. R. E. McBride, Las Cruces.

New York: Albany, Buffalo, New York and Syracuse, June 24-27, Mr. George M. Wiley, director, Exam. and Inspections Div., State Edu. Bldg., Albany.

North Carolina: Raleigh, June 23. Sec., Dr. H. A. Royster, 423 Fayetteville St., Raleigh.

North Dakota: Grand Forks, July 1-4. Sec., Dr. G. M. Williamson, 860 Belmont Ave., Grand Forks.

Oklahoma: Oklahoma City, July 8-9. Sec., Dr. J. J. Williams, Weatherford.

Oregon: Portland, July 1-3. Sec., Dr. Frank W. Wood, 559 Morgan Bldg., Portland.

Pennsylvania: Philadelphia and Pittsburgh, July 8-10. Sec., Nathan C. Schaeffer, State Capitol, Harrisburg.

Rhode Island: Providence, July 10-11. Sec., Dr. B. U. Richards, State House, Providence.

South Dakota: Deadwood, July 8. Sec., Dr. P. B. Jenkins, Waubay.

Texas: Austin, June 24-26. Sec., Dr. M. F. Bettencourt, Mart.

Utah: Salt Lake City, July 7-8. Sec., Dr. G. F. Harding, 407 Templeton Bldg., Salt Lake City.

Vermont: Burlington, June 26-28. Sec., Dr. W. Scott Nay, Underhill.

Washington: Seattle, July 1-3. Sec., Dr. C. N. Suttner, 415 Old National Bank Bldg., Spokane.

West Virginia: Huntington, July 8-10. Sec., Dr. S. L. Jepson, Masonic Bldg., Charleston.

Wisconsin: Milwaukee, June 24-26. Sec., Dr. J. M. Dodd, 220 E. 2nd. St., Ashland.

Wyoming: Cheyenne, June 23-25. Sec., Dr. H. E. McCollum, Laramie.

REGULATIONS GOVERNING MEDICAL PRACTICE IN AUSTRALIA AND NEW ZEALAND

New South Wales.—The candidate for registration is required to communicate with the secretary of the Medical Board of New South Wales, Sydney, at least five days before a monthly meeting, which is held on the second Wednesday in every month, and to submit his diploma or other certificate of qualification. The candidate is required to prove to the satisfaction of the board: (1) that he is a doctor or bachelor of medicine of some university, or a physician or surgeon licensed or admitted as such by some college of physicians or surgeons in Great Britain or Ireland; or (2) that he has passed through a regular course of study of not less than five years' duration in a school of medicine, and that he has received from some university, college or other body duly recognized for that purpose in the country to which such university, college or other body may belong, a diploma, degree or license entitling him to practice medicine in that country; or (3) that he is a member of the Company of Apothecaries of London or of the Apothecaries' Hall, Dublin; or (4) that he is a medical officer of His Majesty's sea or land service, or (5) that he is a person placed on the separate register under Section 8 of the Act (Nov. 29, 1912). The penalty for using the title of physician, Doctor of Medicine, Licentiate in Medicine and Surgery, or Bachelor of Medicine is about $250, and in case of continuing offense, $25 a day from the date of the first offense or imprisonment for a term not exceeding twelve months.

Queensland.—The candidate for registration must submit his diploma or other certificate for approval to the Medical Board of Queensland, at Brisbane. The board meets on the first Thursday of every month. A candidate must have passed through a regular course of medical study in a school of medicine and received from some college, university or other body, duly recognized for that purpose in the country to which such university, college or other body may belong, a diploma or license entitling him to practice medicine in that country, or must be a person who is, or has been, a medical officer, duly appointed and confirmed, of His Majesty's sea or land service. In dealing with diplomas and certificates of qualification, the essential point is that the board must be satisfied. The penalty is similar to that of New South Wales.

South Australia.—Any person who wishes to be registered as a medical practitioner must give to the secretary of the Medical Board of South Australia, Adelaide, at least three days' notice of his intention to apply. This board meets on the second Thursday in every month. He must submit his diploma and produce a declaration, signed before a justice of the peace, to the effect that he is the person whose name appears on the diploma. The fee for registration is about $5. The applicant must have a medical degree, diploma or license to practice, granted by a university, college or licensing body of any British colony or possession or by any foreign university, college or licensing body which in the opinion of the medical board is equal to the qualification entitling the holder to be registered in the United Kingdom. He must satisfy the board that he has passed through a regular graded course of medical study of not less than four years' duration in a British or foreign school of medicine, and has received from such college, school or university or body duly recognized for that purpose in the country to which such institution may belong, a medical diploma or degree certifying to his ability to practice.

Tasmania.—No one is deemed a legally qualified medical practitioner who is not the holder of a certificate of qualification from the Medical Council of Tasmania, Department of Public Health, Hobart, Tasmania. Applicant shall present to the council (which meets on the first Tuesday in each month) the testimonium, diploma, license or certificate from some university, college or other body duly recognized for such purposes in the country to which such university, college or other body may belong. Subject to the foregoing qualifications, the council may register duly certified holders of British registrable degrees. The registration fee is about $15.

Victoria.—The office of the Medical Board of Victoria is the Chief Secretary's Department, Spring Street, Melbourne, Victoria, and the monthly meeting for registration takes place on the first Tuesday of every month. To be entitled to registration, an applicant must have passed through a regular course of medical and surgical study of five or more years' duration. Persons holding British registrable degrees may be registered. No university or college or other body in any country other than the United Kingdom or a British possession is recognized by the board unless registered legally qualified medical practitioners of Victoria are, by virtue of being so registered, and without further examination, entitled to practice their profession in such country, either on registration or otherwise. The fee for registration is about $15. The penalty is similar to that of New South Wales.

Western Australia.—Applicants must submit their degrees, diplomas, certificates or other proofs to the Medical Board of Western Australia, Public Health Department, Perth, West Australia, together with proof of good character and qualification, skill, and ability to practice medicine or surgery. Only persons holding British, Australian, Tasmanian or New Zealand qualifications and those holding the registration certificate of the General Medical Council of Great Britain can be registered.

New Zealand

In order to be registered the applicant must cause at least one month's notice of his intention to apply to be published in the *Gazette,* and also in some newspaper circulating in the district in which the applicant intends to practice; and at least one month before the date of his application for registration he must deposit his diploma or other evidence of qualification, or a true copy thereof certified as correct, in the office of the registrar nearest to the place where he intends to register. The applicant may then apply to the registrar-general, Wellington, New Zealand, for registration, forwarding with his application a copy of the advertisement and *Gazette* notice. The applicant must satisfy the board that he is (1) a graduate in medicine and surgery of the University of New Zealand; or (2) registered on the register of medical practitioners in the United Kingdom; or (3) eligible for registration on such, or (4) the holder of a diploma approved by the board. The board may refuse to approve any diploma unless the graduates in medicine and surgery of the University of New Zealand are by virtue of such graduation, and without further examination, entitled to be registered in the country in which is situated the university or other institution by which this diploma has been granted. No person is entitled to be registered if he has been convicted of any offense punishable by imprisonment with hard labor for a term of two years or upward or is otherwise not of good character.

A fee of about $15 is payable when the diploma or other evidence of qualification is deposited. There is a slight charge for a certificate of registration or for alteration or addition to qualifications to register. The act took effect, March 1, 1915.

New Mexico January Examination

Dr. W. E. Kaser, secretary of the New Mexico Board of Health and Medical Examiners, reports that 7 candidates were licensed on credentials and 1 candidate was licensed through reciprocity, at the meeting held at Sante Fe, Jan. 13-14, 1919. The following colleges were represented:

College	LICENSED ON CREDENTIALS	Year Grad.	No. Licensed
Rush Medical College		(1906)	1
Kansas City Medical College		(1895) (1903)	2
Willamette University		(1907)	1
Medical College of Ohio		(1900)	1
Western Pennsylvania Medical College		(1901)	1
Vanderbilt University		(1900)	1

College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
University of Arkansas		(1916)	Arkansas

Colorado April Examination

Dr. David A. Strickler, secretary of the Colorado State Board of Medical Examiners, reports the written examination held at Denver, April 1, 1919. The examination covered 8 subjects and included 80 questions. An average of 75 per cent. was required to pass. Of the 16 candidates who took the physicians and surgeons examination, 14, including 8 osteopaths, passed and two osteopaths failed. Seventeen candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Hospital College of Medicine, Louisville		(1901)	80.6
Eclectic Medical University		(1910)	75
Washington University		(1918)	82.3
Jefferson Medical College		(1915)	87.2
Vanderbilt University		(1916)	80.6
University of Tennessee		(1912)	80.3

College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
College of Physicians and Surgeons, Chicago		(1902)	Illinois
Keokuk Medical College		(1898)	Illinois
Tulane University		(1912)	Louisiana
University of Maryland		(1915)	Washington
University of Michigan Homeo. Medical College		(1906)	Michigan
College of Physicians and Surgeons, St. Louis		(1897)	Missouri
University Medical College		(1897) Iowa; (1903)	Kansas
University of Kansas City		(1884)	Missouri
Washington University		(1917)	Missouri
John A. Creighton Medical College		(1901)	Nebraska
Bellevue Hospital Medical College		(1889)	Iowa
Western Reserve University		(1905)	Ohio
Tennessee Medical College		(1894)	Kansas
University of Nashville		(1907)	Tennessee
Baylor University		(1909) Texas; (1916)	Texas

Book Notices

Human Infection Carriers: Their Significance, Recognition and Management. By Charles E. Simon, B.A., M.D., Professor of Clinical Pathology in the University of Maryland School of Medicine and the College of Physicians and Surgeons, Baltimore, Maryland. Cloth. Price, $2.25. Pp. 250, with illustrations. Philadelphia: Lee & Febiger, 1919.

This book gives the impression that it has been written rather hurriedly, the consequence being that while many facts in regard to human infection carriers are included, yet the book does not constitute a well digested and thorough summary of our present knowledge of this subject. The use of the terms "active" and "passive" carriers, to denote that in one case the carriers have actually been infected with the germs in question and that in the other the germs have played a purely passive rôle, seems unfortunate because the impression may be conveyed that the carrier himself may be active or passive. In the chapter on carriers in epidemic meningitis, no reference is made to the standard technic of meningococcus carrier detection adopted by the medical departments of the United States Army and Navy and by the United States Public Health Service, and which represents an earnest effort to formulate a satisfactory technic for general practical use. The chapter on influenza proceeds as if the Pfeiffer bacillus had been accepted definitely as the cause of a certain type of pandemic influenza. It is remarkable that in a book published in 1919 the only reference to the literature on influenza should be to German contributions. In fact, in connection with no disease discussed in this book does it appear that the literature has been studied thoroughly and systematically; and yet to know what has been done in any field will ever be the only basis for a satisfactory presentation of the problems of that field. American medicine would be held in greater respect if hastily prepared books with little evidence of scholarship were not published.

Aspect of Death and Correlated Aspects of Life in Art, Epigram, and Poetry. Contributions Towards an Anthology and an Iconography of the Subject. Illustrated Especially by Medals. Engraved Gems, Jewels, Ivories, Antique Pottery, etc. By Frederick Parkes Weber, M.A., M.D., F.R.C.P. Third edition. Cloth. Price, $7.50 net. Pp. 786, with 145 illustrations. New York: Paul B. Hoeber, 1918.

This edition of a most interesting work has been greatly enlarged and thoroughly revised. It is a veritable anthology of death, the author having gathered together all that is beautiful, romantic, witty, humorous, pessimistic or artistic concerning the end of human life. Peculiarly, the book is not pessimistic in tone, but gives the distinct impression that mankind in mass has ever viewed death philosophically. The book contains thousands of quotations from literature and more than one hundred interesting illustrations. The reader, in fact, is left with the impression given by the old English couplet

> To look on life with placid eye,
> And neither fear nor wish to die.

War Surgery of the Face: A Treatise on Plastic Restoration after Facial Injury. By John B. Roberts, A.M., M.D., F.A.C.S., Professor of Surgery in the University of Pennsylvania Graduate School of Medicine. Prepared at the Suggestion of the Subsection on Plastic and Oral Surgery Connected with the Office of the Surgeon General. Cloth. Price, $4.50. Pp. 442, with 256 illustrations. New York: William Wood & Co., 1919.

The author has endeavored to correlate the literature arising from the experiences of general and oral surgeons in the army and navy services of the various nations recently at war, adding to this material the results of civil practice in traumatic surgery of the face. The book is therefore of decided interest in the field of industrial surgery, since reparative surgery of the face following wounds received in warfare is identical with the treatment of wounds caused by industrial accident. The work is divided into three parts, the first part consisting of a comprehensive outline of the surgical anatomy of the face. The pathology and treatment of facial wounds of every description is considered in the second part. The third part takes up the reconstructive treatment of war injuries of the face. The book completely covers the field of war or accidental surgery, and is readable and instructive.

Vital Statistics: An Introduction to the Science of Demography. By George Chandler Whipple, Professor of Sanitary Engineering in Harvard University. Cloth. Price, $4. Pp. 517, with illustrations. New York: John Wiley & Sons, Inc., 1919.

This text has been prepared by the author especially for students in courses on public health. It tells what statistics are, how to express vital facts by figures, how to tabulate them, how to compute birth rates and death rates, how to adjust and standardize death rates, and how to make life tables. It contains also the international list of causes of death and an excellent table of logarithms for making computations. This book shows why figures sometimes lie and also tells the reader how to tell which figures lie and which figures tell the truth. The text is very fully illustrated with numerous diagrams, charts and tables. While not strictly a medical book, this handbook is one which every physician who is at all interested in public health will find of particular value.

Medicolegal

Board of Health Closing Schools for Influenza

(Globe School District No. 1 v. Board of Health et al. (Ariz.), 179 Pac. R. 55)

The Supreme Court of Arizona affirms a judgment in favor of the defendants in this action, wherein the plaintiff board of school trustees of the school district of the city of Globe sought to enjoin the local city board of health and the city officers from enforcing a health order or regulation closing the schools during the epidemic of Spanish influenza. The court holds that the measure adopted by the local board of health, closing the schools of the Globe school district, was, at the time adopted, a valid, enforceable order and regulation for the purpose of reasonably protecting the public health, under the statutory authority to make and enforce all needful rules and regulations for the prevention and cure, and to prevent the spread of any contagious, infectious, or malarial disease among persons; that during the existence of said Spanish influenza in epidemic form in said community said regulation was binding on the educational administrative officers, and continued binding so long as such epidemic continued in such form, and no longer.

The court says that to concede that any board of health has been delegated the legislative power to declare what is or what is not a nuisance is to concede that boards of health may be delegated legislative power, and this cannot be done. Such boards of health may abate nuisances, and in so doing, if they mistake that for a nuisance which is not in fact a nuisance, then the board acts without jurisdiction, because the existence of a nuisance in fact gives the board the power to act. No portion of the health laws of Arizona attempts to or could grant to health boards the authority to arbitrarily declare a given condition a nuisance. An attempt by such board to declare what is or what is not a nuisance is futile, null and void. Therefore, that portion of the resolution of the defendant board of health which attempted to define nuisances, and which declared certain assemblies, including school sessions, nuisances, was without authority of law and of no force or effect.

But the material thing here was the order closing the schools; and it seems clear to the court that the statute and the public exigency were sufficient to justify the order of the local board of health prohibiting the educational officers from holding sessions of school. But the exigency is met and satisfied by the disappearance of the infectious or contagious disease. As a matter of police regulation, the authority of the board of health over the schools ends with the necessity of the regulation. The court has found no adjudicated case that denies the power of public bodies exercising the authority of supervising the public health, such as boards of health established by the laws of Arizona, to make a valid order closing schools at times when infectious or contagious disease is epidemic in the community, as was admittedly the situation at Globe when the orders here in question were made. The court does find, on the other hand, cases wherein the courts treat, as a matter of course, the right of health officers to close schools at times of such emergency.

While school trustees and educational administrative officers are invested with power to establish, provide for, govern, and regulate public schools within their respective jurisdiction, they are in these respects nowise subject to the direction or control of the state or county or city boards of health, yet when the necessity arises to close the schools for the protection of the public health such emergency, while it exists, is a superior power to that given the school administration officers, and the law of necessity controls the situation during the existence of the emergency giving rise to the power. And while local boards of health are no authority conferred on them to legislate, they are granted power within their jurisdiction to make rules and regulations to facilitate the enforcement of the health laws, and in exercising such powers they may adopt such measures as are reasonable to carry out such health laws according to the true spirit and intent of the legislature.

Physician Contracting for Salary and Employer Fees

(Sherrill v. Union Lumber Co. (Texas), 207 S. W. R. 149)

The Court of Civil Appeals of Texas affirms a judgment in favor of the defendant company, which was sued by the plaintiff, a physician, for $1,753 which he claimed was due him for medical treatment rendered to injured employees of the company during the first week of their injuries, in accordance with the workmen's compensation act of the state, notwithstanding an alleged contract between him and the company that he should receive a salary or designated compensation for his services, leaving for the company the medical fees which should be paid by the insurer carrying the risk on the employees for medical services rendered during the first week of their injuries. The court says that if, as was substantially found by the jury, the plaintiff, on entering the employ of the defendant as a physician at its mill plant, entered into an agreement or understanding with the defendant to the effect that he should be paid a certain cash compensation for his services in treating the employees of the millyard, with the further understanding or agreement that he would forbear to claim the fees for which the insurer might become liable to him for his services to injured employees during the first week of injuries, under the workmen's compensation act of the state then in effect (Act of 1913), and, further, that such fees might be collected and retained by the defendant, then the court can see no reason for holding that such contract was in violation of the public policy of the state, and it therefore declines to so hold. But if the court is wrong in this view of the question, and if the necessary tendency of such contract was vicious and against sound public policy, still there would be a serious question as to whether the court ought to sustain the plaintiff's assignment of error on this point, for the reason that if the contract was made he was undeniably a party to it, and if the same was vicious, and necessarily tended to injure the public generally, or any class or members of the public, or was against the public welfare in any respect, and therefore against sound public policy, then it must be admitted that the plaintiff was in pari delicto or equal legal fault with the defendant in entering into the contract. It seems to the court that the plaintiff should not be permitted to profit by the contract to the extent of receiving and retaining the compensation that was allowed him by the defendant under its terms, and at the same time repudiate that portion of the contract which gave to the defendant the right to collect and retain the fees paid by the insurer, and which were held by the defendant under the terms of the claimed contract. If it should be held that the plaintiff could assail this contract so far as it permitted the defendant to have and receive the money to be paid by the insurer on the ground of public policy, then it would be to hold, in effect, that the plaintiff might take advantage of a vicious and illegal contract to which he was undeniably a party, so far as it was beneficial or favorable to him, and repudiate it in all respects where not so. For this reason alone the court would be inclined to overrule the assignment of error, even if it were of the opinion that the tendencies of the contract were such as to make it against public policy.

Unnecessary Roentgenoscopy Not Required

(United States Fidelity & Guaranty Co. et al v. Wickline (Neb.), 170 N. W. R. 193)

The Supreme Court of Nebraska holds that a claimant for compensation under the employers' liability act pursuant to Section 3675 of the Revised Statutes of Nebraska of 1913, cannot be denied a recovery because of a refusal to submit to a roentgen-ray examination or to have a roentgenogram taken of the person, where the uncontradicted evidence shows that neither was necessary. Section 3675 provides that, after an employee has given notice of an injury he shall, if so requested by the employer or the insurance company carrying such risk, submit himself to an examination by a physician or surgeon furnished and paid for by the employer or the insurance company, and refusal of the employee to submit to such examination shall deprive him of the right to compensation during the continuance of such refusal. The court says that under the statute the request for an examination must be reasonable, and it did not appear to have been in this case. The testimony before the court showed affirmatively that neither a roentgen-ray examination nor a roentgenogram was necessary. No physician nor other person testified that either was necessary, nor did it appear that a request was made to the court to require the employee to submit to either. In the present advanced state of the science of roentgen-ray examinations and the taking of roentgenograms of the person there appears to be no reason why such examination or roentgenogram should not be permitted by a claimant for compensation under the employers' liability act, on request by the employer or insurer, unless the request is shown to be unreasonable.

Liability of Physicians and Manufacturer of Ether

(Moehlenbrock v. Parke, Davis & Co. et al. (Minn.), 169 N. W. R. 541)

The Supreme Court of Minnesota affirms an order denying the defendant company's separate motion for either a judgment in its favor or a new trial, in this action against two physicians and the company to recover damages for the death of one Moehlenbrock, in which a verdict was returned in favor of the plaintiff, as administrator, against all of the defendants. The court says that Moehlenbrock, a man 21 years old, robust and apparently in good health except for diseased tonsils, died just after being operated on for the removal of his tonsils. One of the defendant physicians operated, and the other administered the anesthetic, using a brand of ether manufactured by the defendant company. While the ether was being given, it was noticed that the patient became cyanotic, and it was necessary to stop and revive him to some extent before proceeding. After the tonsils were removed, he lapsed into the same condition several times, and finally, within about three hours from the commencement of the operation, all efforts to revive him failed and he died.

The plaintiff claimed that the physicians contributed to the fatal result by their negligence in the administration of the ether, and that the company also contributed thereto by its negligence in manufacturing and placing impure and dangerous ether on the market for anesthetic purposes. Under the charge thus made, of distinct and differing acts of negligence concurring to bring about Moehlenbrock's death, the physicians and the company were placed in a peculiar antagonistic position. For, in addition to other defenses, it was a good defense for the physicians to show that the fatal outcome was due wholly to impurities in the ether, a defect they could not anticipate; and for the company to show the carelessness of the physicians as the sole cause. That made the defendants, in a measure, adverse parties to each other; and because of such antagonistic positions the company was accorded a wide range in cross-examining the physicians, even though called by the plaintiff for cross-examination.

Complaint was made of rulings allowing the defendant physicians to express an opinion as to the cause of death, confirmed, as they admitted it was in part, by information acquired afterward, concerning an analysis of ether made by a chemist; but the court thinks there was no error here. As professional men, the physicians were competent to express an opinion as to the cause of death. The value of that opinion was for the jury; they determining whether the physicians were justified in relying, for corroboration of the opinion expressed, on the presence in the ether as administered to Moehlenbrock of the impurities testified to by the chemist.

The identification of the ether analyzed as that administered to Moehlenbrock, and to another patient the next day, being sufficient, and the evidence sufficient that there had been no change in the condition of the ether during the twenty-four hours between the two operations, it would be proper, both for the experts and the jury, to consider the similarity of the effects of the ether on the two patients in determining the cause of death. It is common knowledge that human beings are physically sufficiently alike so that we may reason that when a drug or substance produces a marked effect on one person it will, to a certain extent, similarly affect another, taking into account age, strength and other conditions present. In fact, the healing art is largely predicated on this similarity of cause and effect in different persons.

The physicians were not the agents nor servants of their patient, so that their negligence could be considered his negligence, to be taken advantage of as a defense by one who, by an independent act of negligence, also proximately contributed to the injury. Nor was the company entitled to regard the operation as a joint enterprise on the part of Moehlenbrock and the physicians, so as to escape liability for its own negligence. In the actual conduct of the operation Moehlenbrock could take no conscious part. It was the joint enterprise of the physicians only.

It was not necessary to prove that the dangerous condition of the ether was known to the company. It was its duty to know that the article it placed before the medical profession did not contain dangerous and unsafe impurities, and was so put up that these impurities could not form in the container, when kept according to directions.

Admissibility of Evidence as to Operations in Hospitals

(Sparer v. Travelers' Insurance Co. (N. Y.), 173 N. Y. Supp. 673)

The Supreme Court of New York, Appellate Division, First Department, says that, in this action on a life insurance policy issued by the defendant on the life of one Sparer, who died in a hospital after an operation for cancer of the stomach, the defendant sought to prove by the operating and assistant surgeon at the hospital, and by the hospital records, the condition the insured was in at the time of the operation; but this was properly excluded under Section 834 of the Code of Civil Procedure, prohibiting disclosures by physicians and surgeons. However, the defendant then called a physician who at the time of the operation was a medical student and in that capacity attended the operation, and he was permitted to testify that when Sparer's body was exposed on the operating table he saw a scar on his abdomen and when the abdomen was opened it showed that an operation known as posterior gastroenterotomy had been performed. The defendant tried to put in evidence another hospital's record of the case, which, it is held, was properly excluded. But the court thinks it was erroneous to exclude an offer of proof by a surgeon that, at such other hospital, between certain dates, he performed an operation on the body of the insured. He could not have described the operation, or any condition that he observed which was necessarily disclosed by an inspection of the body of the insured; but he could have testified that he at a certain time performed an operation on the insured at the hospital.

Social Medicine, Medical Economics and Miscellany

Health and Hours of Labor

The human factor in industry is subject to certain limitations. One of these is that a man or a woman cannot work continuously to good effect except within limits. Beyond a certain number of hours of work in a given day a worker's efficiency and production rate decrease. Long hours maintained for weeks or months impair the health of the worker. The day's work may be so long or so arduous that the worker does not have time or energy to devote to cultural, recreational or family interests. These are facts concerning which there is more or less general agreement.

How many hours shall constitute a day's work, considered in the interests of health and efficiency, is not easy to determine. Industry, interested primarily in production, would regulate hours in relation to output. This does not mean that individual employers and firms are not sometimes prompted by humanitarian motives in matters relating to the welfare of their employees. Yet in general the attitude of industry toward measures for the promotion or protection of the health and comfort of workers seems to depend on the relation of these measures to efficiency and cost of production. Studies have been made in various industries to determine what should be the standard work day or work week.

An investigation made in the silk manufacturing industry by the National Industrial Conference Board has shown that, as a whole, maximum output lies at some point between fifty and fifty-four hours a week. Similar studies made in the cotton manufacturing and the wool manufacturing industries indicates that the point of maximum production falls below a fifty-four hour week. As to health, there was found no perceptible difference between the health of employees who worked fifty hours a week and that of those who worked fifty-two or fifty-four hours. Public interest in the length of the work day or the work week lies chiefly in the relation between the hours of work and the health of the worker. The maximum number of hours which an individual may work per day or per week without endangering health depends largely on the age and sex of the worker and the character of the work. Little effort has been made to regulate by law the length of the working day of men except in certain industries and as regards overtime. Two states, Oregon and Mississippi, have ten hour laws for male workers in most industrial employment. In all but one or two states, the hours of child workers between the ages of 14 and 16 or 17 are regulated by law. Thirty-eight states (including the District of Columbia) have laws regulating the length of the work day and the work week of women. In seven states there is an eight hour day; in eleven states a nine hour day; in twenty, a ten to eleven hour day. Two states make the maximum work week *forty*-eight hours; fifteen make it from fifty-four to fifty-five hours; eleven make it from fifty-six to fifty-seven hours; eight, from sixty to sixty-three hours, and two permit a seventy hour week. Fifteen states regulate night work of women, ten prohibiting it altogether.

In Illinois, which now has a ten hour law for women workers, a state commission headed by Dr. James B. Herrick has recently made a study of the relation between hours and health of women workers. A majority of the commission has reported in favor of an eight hour day and a forty-eight hour week and has recommended their establishment by law, such regulation to apply to all industries covered by the ten hour law now in force, "including all office workers and excepting graduate nurses" (Report of the Illinois Industrial Survey, December, 1918). The commission based its recommendations, so far as the health of employed women is concerned, on the fact that a longer day than eight hours and a longer week than forty-eight hours affect health primarily as they produce fatigue.

Fatigue is generally recognized as being the most important effect on the worker of either long hours or intensity of occupation. It may be considered in both its temporary and its cumulative effects. Temporary fatigue, by its effect on vision, hearing, attention, muscular control and reaction rate, tends to lessen production and to increase the danger of accidents. Cumulative fatigue frequently results in illness, with resultant absence from work and attendant loss to both employer and employee. Investigations of the effect of rest periods in reducing temporary fatigue and preventing cumulative fatigue (as reported in Rest Periods for Industrial Workers, Report of National Industrial Conference Board, January, 1919) lead to the conclusion that for certain occupations short rest periods of from five to fifteen minutes in the middle of both the forenoon and the afternoon may be beneficial to the health of the employee and tend to increase his production.

International Red Cross Conference

Representatives from the Red Cross societies of the United State, France, Great Britain, Italy and Japan met at Cannes (France) in April to propose to the Red Cross organizations of the world an extended program of future activities in the interest of humanity. One of the delegates of the Red Cross of Great Britain was Sir Arthur Newsholme, K.C.B., M.D. At a meeting held May 2 at the national headquarters of the American Red Cross in Washington, D. C., Sir Arthur reported briefly on what was done at the Cannes conference.

The conference held a number of general meetings in which the general policy to be pursued was discussed and then divided itself into sections dealing with the following subjects: preventive medicine, child welfare, tuberculosis, malaria, venereal diseases, nursing, information and statistics. These sections were not selected as covering the entire ground of preventive medicine, but as forming branches of work in which early investigation and action appeared to be most desirable. The conference agreed that the new work of the Red Cross would naturally divide itself into two parts: an international bureau and national organizations. The international bureau, in the scheme proposed for the consideration of the conference—which received general approval—would act as a great center for collecting information on various public health subjects, and for digesting it and subsequently distributing it by means of special publications, or periodical journals, or on application from those requiring specialized information. It would also act as a means of educating the general public on urgent problems affecting its welfare; and it would be utilized as a center, organizing in less favored communities missions which would undertake local investigations and remedial work. These surveys and activities would be intended rather as demonstration centers than as permanent organizations, the intention being to withdraw them as soon as the necessary work could be carried on by local Red Cross or other organizations.

It was suggested that the central bureau should comprise a number of branches dealing with epidemic diseases, tuberculosis, venereal diseases, child welfare, nursing and other subjects, collating and analyzing information and distributing it through the medium of the national Red Cross of each country. Such a central bureau will be of the greatest value to all social and public health workers, while not clashing with any existent agency. The relation of the central bureau to national Red Cross societies will be one of mutual cooperation. The central bureau will provide information and facilities for national work; the actual work will need to be carried out in each country nationally and in the main from funds supplied by that country. It is not intended that the National Red Cross shall undertake, much less compete with, work already being carried out either by local authorities or by existing voluntary associations.

Among the more urgent problems of preventive medicine, priority was given to advocacy of combined efforts for the prevention of the major pests of mankind, of the provision of laboratory assistance in the diagnosis of disease and in securing more accurate vital statistics and improvements in public health legislation. In child welfare work, the importance of health visiting, of child welfare centers, of an improved midwifery service and of continuous observation of children under school age as well as scholars was emphasized. In regard to tuberculosis, stress was laid on the essential point that measures against this disease must embrace the whole of the sick lifetime of the patient, and must include, when necessary, measures for obviating the results arising from the fact that the partially recovered patient commonly is unable to earn an economic wage. In the prevention of venereal diseases a similarly wide outlook was advocated, including the necessary social and moral as well as medical measures against their spread.

Inequality of the Pupils

The question of the meaning of inequality of the pupils is always being raised for diagnostic purposes, especially in affections of the thorax. According to many authorities, "inequality of the pupils is always pathologic"; but many observers are not so dogmatic, and admit that the condition occurs in from 1 to 10 per cent. of all cases.

In order to gain some idea of the frequency of this condition, T. Stewart Barrie examined, for this peculiarity, in the course of his work as an ophthalmic surgeon in the Glasgow recruiting area, the eyes of 326 men who had been sent for special examination. The results are given in the *British Medical Journal,* Nov. 9, 1918. Inequality of the pupils was found in thirty-five cases, a proportion of 10.73 per cent. In none of these cases was there any sign of ocular disease or manifestation of disease of the central nervous system. The pupils reacted readily to light, and the consensual and convergence reflexes were normal; in each case the inequality persisted in the contracted state.

The inequality in every case was indisputable, the difference between the diameters of the two pupils being from 1 to 2 mm. This difference is not large, but as pupils are compared by areas it was easier to note differences than to measure them. For example, pupils having diameters of 3 and 2 mm., respectively, have areas in the proportion of 9 and 4.

An analysis of these thirty-five cases gave the following results:

1. The left pupil was the larger in twenty-one cases, the right in fourteen.
2. The visual acuity without glasses was the same in ten cases; the right eye had the higher visual acuity in eight cases, the right pupil being the larger in four; the left eye had the higher visual acuity in seventeen cases, the left pupil being the larger in thirteen.
3. The refractive condition of the thirty-five cases was as follows:

Emmetropia	2
Hypermetropia	2
Hypermetropic astigmatism	2
Myopia	11
Compound myopic astigmatism	1
Mixed astigmatism	3
Anisometropia	9
Not recorded	5

The conclusions that may be drawn from this investigation are:

1. Inequality of the pupils is frequent.
2. It is associated with all refractive conditions, with a tendency to be more frequent in myopic conditions.
3. The visual acuity is not affected adversely by the fact that one pupil is slightly larger than the other.
4. The left pupil is more frequently larger than the right.
5. Inequality of the pupils occurs as a physiologic condition.

Tuberculosis Among Industrial Workers

The Medical Research Committee, London, England, has made a study of the effect of occupation on the morbidity and mortality of tuberculosis among industrial workers because of the increase in both, especially among women workers in munition factories (Special Report, Series 22, 1919). While the death rate among certain groups of occupations was unusually high as compared with other occupations, it was felt that it was not so much the occupation itself as the environment and poor hygiene which were responsible for the higher death rate. The incidence of the disease is still too heavy to be explained as a by-product of inferior physique independent of the factory environment itself. The data with regard to the women workers were too insufficient to permit of arriving at any satisfactory conclusions, but statistics from other countries, particularly Germany and Austria, where women have been engaged in heavy occupations for many years, show a higher incidence of tuberculosis among the workers, thus bearing out the observations made thus far in England. The greater incidence of tuberculosis among town dwellers could not be accounted for by the general lowering of health associated with living in cities, whereas industrial employment does account for such an increase because it introduces a special factor making for the development of tuberculosis. Special attention was paid by the committee to factory conditions and the observations made previously by other similar commissions were fully verified and confirmed. A very terse summary of the recommendations of the committee might be made as follows: Improve the hygienic conditions of factories; prevent overcrowding in industrial dwellings; take every precaution to remove and prevent the development of specific trade habits which favor the spread of tuberculosis from person to person; make every effort to enforce the measures of prophylaxis against the disease.

Discussions on Influenza in Japan

An occasional correspondent sends us from Japan the following report of several recent meetings devoted to discussions of the influenza epidemic:

Society of Internal Medicine of Japan.—At a recent meeting of this society, held in Kyotto, R. Miki stated his conviction that Pfeiffer's bacillus is the primary cause of the last influenza epidemic, and that diplococci occur as secondary invaders. Dr. Onodera laid stress on the meteorologic relation of the occurrence of influenza epidemics, the latter running parallel with the severe cold that returns at about thirty year intervals. Dr. Yabe has always found a diminished leukocyte count in cases of influenza. Dr. Tsuneoka found that the disease, as well as vaccine made from the Pfeiffer bacillus, confers immunity.

Society of Hygiene of Japan.—A meeting of this society was held in Tokyo, April 3. Dr. Ishiwara and his associates demonstrated the influenza bacillus in from 45 to 69 per cent. of all cases of influenza and in from 35 to 55 per cent. of the cases of measles, scarlet fever and diphtheria. Therefore, they do not believe that it is the specific cause of influenza.

Pathological Society of Japan.—At a recent meeting of this society, held in Kyoto, Dr. Katsurada stated his belief that the Pfeiffer bacillus is not the specific cause of influenza; nor is a filtrable virus. He has found a micrococcus, however, to which he ascribes an etiologic relationship to influenza.

Alumni Meeting of Kitasato Institute for Infectious Diseases.—At this meeting it was stated that the institute accepts Pfeiffer's bacillus as the cause of influenza and that immunized horse serum is a most efficacious remedy for the disease. An exotoxin produced by the bacillus has been isolated.

Standards for Milk and Cream

Food inspection decision 178, of the United States Department of Agriculture, issued April 17, 1919, promulgates the following definitions and standards for milk and cream, as adopted by the joint committee on definitions and standards July 30, 1917:

1. Milk is the whole, fresh, clean, lacteal secretion obtained by the complete milking of one or more healthy cows, properly fed and kept, excluding that obtained within fifteen days before and five days after calving, or such longer period as may be necessary to render the milk practically colostrum free.
2. Skimmed milk is milk from which substantially all of the milk fat has been removed.
3. Cream, sweet cream, is that portion of milk, rich in milk fat, which rises to the surface of milk on standing, or is

separated from it by centrifugal force. It is fresh and clean. It contains not less than 18 per cent. of milk fat and not more than 0.2 per cent. of acid-reacting substances calculated in terms of lactic acid.

4. Whipping cream is cream which contains not less than 30 per cent. of milk fat.

5. Pasteurized milk is milk that has been subjected to a temperature not lower than 145 F. for not less than thirty minutes. Unless it is bottled hot, it is promptly cooled to 50 F. or lower.

6. Buttermilk is the product that remains when fat is removed from milk or cream, sweet or sour, in the process of churning. It contains not less than 8.5 per cent. of milk solids, not fat.

7. Homogenized milk or homogenized cream is milk or cream that has been mechanically treated in such a manner as to alter its physical properties, with particular reference to the condition and appearance of the fat globules.

SOUTH DAKOTA STATE MEDICAL ASSOCIATION

Thirty-Eighth Annual Session, held at Watertown, May 20-22, 1919

The President, Dr. D. L. Scanlon, Volga, in the Chair

Pyelitis

Dr. J. P. Isaac, Freeman: The routes of infection in pyelitis are commonly accepted to be hematogenous, urogenous and by contiguity. While bacteria are always the primary cause, other accessory factors are important. In the diagnosis of pyelitis, a careful study of the urine is essential. Pus and bacteria, especially the colon bacillus, in the urine, together with pain in the flank resembling lumbago, chills and high fever with remissions to the normal without any definite cause should justify the diagnosis of pyelitis. A further diagnostic aid in adults is ureteral catheterization to determine whether it is the kidney, pelvis or the bladder that is involved. In children, ureteral catheterization is not desirable; but the cystoscope may be used to exclude the bladder as the cause of infection. In the treatment of pyelitis, water must be given freely, and in some cases a milk diet for a few days is advisable. Rest in bed for a time is usually indicated. In medication, hexamethylenamin is most frequently used. In advanced cases, pelvic lavage is much practiced.

Catabolins in Disease

Dr. B. T. Green, Brookings: Nearly every departure from health is complicated to some degree by a toxemia due to the retention in the body of catabolins. These products of retrograde metamorphosis are definite chemical compounds and are mainly tissue poisons.

The extent to which different individuals may be affected by these morbific agents varies greatly. While disease is the usual cause of catabolic toxemia, other factors may produce the condition. Rest reduces the rate of tissue disintegration and permits the emunctory processes to rid the body of the accumulated poisons. On the other hand, weariness results with continued inactivity of brain or muscle. The body fluids stagnate, and catabolins are retained. Prophylaxis consists in the preservation of physiologic balance, and treatment should be directed toward: (*a*) the reduction in the rate of tissue destruction by proper treatment of the disease condition that has increased it; (*b*) the establishing of normal chemical changes by the regulation of physiologic processes; (*c*) the rendering of the reaction of the body fluids normal by indicated corrections in diet or by the administration of acids or alkalis as required, and (*d*) the securing of normal activity of the emunctory organs by proper attention to the existing pathologic condition.

Otolaryngology and the Mortality Rate

Dr. J. G. Parsons, Sioux Falls: Fully 50 per cent. of all deaths are due to tuberculosis, pneumonia, diseases of the kidney, heart and blood vessels, meningitis and a few acute infections, all of which are directly or indirectly concerned with an infection which gains access through the nose and its accessory sinuses and the throat. The presence of chronic pneumococcus, streptococcus and staphylococcus infections makes it possible, under favorable conditions, for pneumonias to develop. Middle ear infections are nearly all secondary to nose and throat infections, and, with their mastoid and intracranial complications, produce 2 per cent. of the mortality. Focal infections, so largely responsible for the death rate in middle life from cardiac, renal, circulatory and organic disease, are found in the tonsils, the nasal accessory sinuses and the ear. Thorough removal and drainage of these focal infections is indicated.

Health Conservation

Dr. D. L. Scanlon, Volga: Properly to conserve the health of the people we must have a thoroughly organized corps of expert public health workers, supported by an adequate appropriation. I recommend that a commission on public health be appointed by the governor for the purpose of studying the needs of our state and thus offering a tangible basis for the necessary legislative action. A matter of such importance as this is worthy of mention in a message from the governor to the legislature.

Leukocyte Count in Chronic Tonsillar Infections

Dr. J. M. Walsh, Rapid City: Among 200 cases, only two patients at the time of operation had a white blood count of less than 10,000. The highest white blood count was 38,000. Twelve had a count of 25,000 and more. The postoperative count in every case was lower than 9,000.

Operation for Acute and Subacute Mastoiditis

Drs. H. I. Lillie and R. A. Barlow, Rochester, Minn.: In cases of definite mastoiditis, operation is indicated reasonably early. The mortality is practically nil. Preservation of the hearing function is fairly certain. A second operation should not be necessary, except for a complication, such as sinus thrombosis or brain abscess.

Myomectomy Versus Hysterectomy

Dr. E. O. Giere, Watertown: In the woman past the age of 45 it is doubtful if myomectomy offers a single advantage over hysterectomy. On the other hand, myomectomy carries with it certain distinct disadvantages which must not be ignored, regardless of the age of the patient. Myomectomy does not make recurrence impossible. Myomectomy leaves possible the occurrence of malignancy. Considering the advantages and disadvantages of both operations, it does not appear justifiable to make myomectomy the operation of choice as a general rule in dealing surgically with myoma of the uterus. Myomectomy should be limited to patients in the child-bearing period; and the younger the woman, the more urgent should be this particular operation and, exceptionally, to women of any age where the tumor is single and pedunculated, provided there is a reasonable assurance that there may not be present small, undeveloped growths, and where malignancy can be ruled out beyond a question of doubt.

Treatment of Empyema

Dr. Arthur T. Mann, Minneapolis: In the army hospitals, where comparatively large numbers of empyemas could be given intensive study, it was soon found that early operation led to a high mortality. These men, as a rule, were already so ill from the influenza and from an extreme toxic condition accompanying the pneumonia which preceded the empyema that they were not able to withstand the shock of the operation and of the pneumothorax which accompanied the operation. These experiences quickly led to aspiration of the early cases of empyema and to repeated aspirations, as often as seemed necessary, until such a time as the patients were in a condition to undergo an operation with every reasonable chance of success. A drop in the mortality, more than could be accounted for by a decrease in the virulence of the infecting organism, was immediately noted. In fact, it was noticed that some patients got well under the aspiration treatment, though the majority of them still came to operation.

At the base hospital at Camp Dodge we undertook the problem of trying to sterilize the infected fluid accumulations and the forming pus at the time of the aspirations. This we did by injecting from 1 to 2 ounces of an active antiseptic fluid at the end of each aspiration. We used three different preparations in this work, namely, surgical solution of chlorinated soda, dichloramin-T and the 2 per cent. solution of liquor formaldehyd in glycerin. The first gave the best results; therefore we discontinued the other two. In selecting the proper time for operation, one must take into consideration the general toxic condition of the patient and the stage of the pneumonia. As a rule, an open operation should not be done until after the crisis is past and the affected areas are undergoing resolution. After watching the good effects of early aspiration in reducing the mortality in the cases which came to operation later when the patient's condition had improved and the pus had become too thick to be withdrawn properly through the aspirating needle, the impression was created that the method of Mozingo would be an improvement on the open method of operation which provides for drainage of pus, but which allows more or less collapse of the lung from the pneumothorax. I am enthusiastic about the method.

Medical Treatment of Gastric Ulcer

Dr. Owen King, Aberdeen: The first and one of the most important things in the successful treatment of gastric ulcer is absolute rest in bed for a period of at least three weeks. This lessens the gastric secretions, thus promoting a more rapid emptying of the stomach. The action of hydrochloric acid on the raw surfaces causes a spasmodic action of the pylorus and hence inhibits the normal emptying of the stomach. The principle of medical treatment is to produce conditions in the stomach in which the stomach contents are neutral or alkaline in reaction in order to remove the irritation at the pylorus. When this condition is obtained and the stomach can empty in a normal period, Nature will heal the ulcer if properly aided. Every case treated surgically should be followed by appropriate medical treatment in order to give the ulcer every oportunity to heal. I do not say that every case of peptic ulcer will respond to medical treatment. There are, no doubt, cases of marked pyloric obstruction from old scar tissue of healed ulcers, and these patients must have surgical treatment. There is an actual mortality of from 3.5 to 4 per cent. in gastro-enterostomy under the best surgeons, and 10 per cent. mortality with the average surgeon, while in the medical treatment there is practically no mortality.

Surgical Treatment of Gastric Ulcer

Dr. R. L. Murdy, Aberdeen: Surgical treatment in the hands of a skilful surgeon gives less mortality than medical treatment. Timely surgical treatment will avert the fatal complications and prevent morbidity in a very large percentage of cases. Excision of the ulcer takes the operation out of the realm of simplicity and adds materially to the danger without securing sufficient compensating advantages to justify the measure. The occasional excision, particularly in deep infiltrated and chronic ulcers with a cancerous tendency and in some others, is desirable and urgent. The location of the ulcer, together with local and general conditions, will also, in a measure, determine the advisability of excision. Ulcers on the greater curvature of the stomach and near the pylorus that can be brought under the alkaline secretions of the duodenum show a greater tendency to heal spontaneously after gastro-enterostomy than those that cannot be alkalized. The observation of Dr. Charles H. Mayo, that gastro-enterostomy greatly lessens the acid of the stomach, and that cancer seldom occurs where the tissues are bathed in this alkaline secretion, can be put to practical use in this connection.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

American Journal of Insanity, Baltimore

April, 1919, 75, No. 4

Work of Psychiatrists in Military Camps. E. S. Abbot.—p. 457.
Nursing Problem as Related to Psychopathology. R. Dewey, Wauwatosa.—p. 467.
Community Mental Health Movement and Its Probable Dependence for Success on a Higher State Hospital Standard for Ward Employees. S. D. Wilgus, Rockford.—p. 473.
Symbolism and Synesthesia. F. L. Wells, Waverly, Mass.—p. 481.
Psychoses in Mental Defects. A. Gordon, Philadelphia.—p. 489.
*Correlation Between Mental Defect and Anomalies of Hard Palate. I. Case, Chicago.—p. 501.
*Correlation of Neurology, Psychiatry, Psychology and General Medicine as Scientific Aids to Industrial Efficiency. J. D. Ball, Oakland.—p. 521.

Correlation Between Mental Defect and Anomalies of Hard Palate.—The analyses of cases examined by Case and others shows that because the palate is imperfect, it does not necessarily follow that mentality is imperfect, i. e., there is no necessary connection between the degree of mental capacity and a high palate.

Correlation of Neurology, Psychiatry, Psychology and General Medicine as Scientific Aids to Industrial Efficiency.—Ball is of the opinion that the establishment of medicopsychologic laboratories as the principal department of employment bureaus of every large industrial organization would be an economic asset and desirable. The establishment of a central employment clearing house with medicopsychologic laboratory which would act for groups of industrial organizations too small to economically conduct their own bureaus is suggested.

Experimental Alteration of Brain Bulk. L. H. Weed and P. S. McKibben, Baltimore.—p. 531.

Epinephrin from the Suprarenals Not Indispensable.—Stewart and Rogoff found that in dogs and monkeys, as previously shown for cats and rabbits, the liberation of epinephrin from the suprarenals is not indispensable for life and health.

Gastric Response to Food.—The subject of the experiments reported by Bergeim et al. was a normal man, 31 years of age, who had the unique ability to deliver samples of stomach contents at will. Not only could this man completely empty his stomach at any desired stage in the process of digesiton but he could also give small samples at short intervals throughout the entire gastric cycle, so that a fractional examination of his stomach contents could be made. Milk drunk rapidly left the stomach sooner and produced a smaller curd mass than milk drunk slowly or "sipped." Raw whole milk formed firm white curds which had "rubberlike" characteristics. The maximum curd formation took place at about one hour after the milk had entered the stomach. These large curds were apparently formed through the coalescing of numerous smaller curds. At this period curds as large as a man's thumb and weighing at least 15 grams may be formed. Milk which had been boiled five minutes curded in an entirely different manner. In this case the curds were small, soft, flaky and of a yellow color. The largest curds were about the size of a small pea. These curds left the stomach sooner and were much more digestible than the tough curds resulting from the ingestion of the raw milk. Dietetically, therefore, boiled milk is to be preferred to the raw product. Particularly tough, hard curds of large size were formed in the human stomach after the entrance of raw skimmed milk. When the skimmed milk was boiled, the resulting curds were not as large and tough as were those of the raw skimmed milk nor as small and soft as were the curds of boiled whole milk. The addition of 2.5 gm. of sodium bicarbonate to 500 c.c. of raw whole milk caused the formation of curds which were smaller and softer than those produced in similar milk in the absence of bicarbonate. There was a definite curd formation at five minutes although the stomach content remained alkaline for thirty minutes. That the bicarbonate treatment was not as effective as was boiling in producing small soft curds was shown by the fact that the curds of the boiled whole milk were smaller and softer than were the curds in the milk after bicarbonate had been added. The boiled milk also left the stomach sooner than the bicarbonate milk. As a general rule, the character of the milk curds was influenced in a very direct way by the fat concentration, i. e., the more fat the less curd. Not only was there less total curd formation but the curds which were formed were smaller and softer the higher the fat concentration. In fact, when 40 per cent. cream was drunk no curds were formed during the first half hour and even then the largest curds were only about the size of the head of a pin and they did not coalesce to form larger curds as was the case in milk of low fat content. The milks of high fat concentration were also very slow to leave the stomach.

Mechanism of Absorption from Intestine.—The apparent property of the intestine of passing dissolved substances in but one direction has been especially difficult of interpretation. This seeming power of the intestine to direct the stream of dissolved substances through the intestinal wall in but one direction, has been a subject of much investigation. Experiments were made by Goldschmidt and Dayton to determine this matter. They found that the colon is not characterized by a strictly one sided permeability. There is a threshold of the colon, below which chlorids diffuse from the blood stream into the intestinal contents. The blood content of chlorids is a factor in determining the height of this threshold. The chlorids diffusing into distilled water or very low concentrations of sodium chlorid in the colon have their origin in the blood.

Id.—Hypertonic solutions of sodium chlorid which readily pass through the intestinal wall were seen to attract fluid into the intestine above a certain threshold value, approximately 1.20 per cent. with a Δ of 0.786. At the same time chlorids pass in concentrated solutions into the blood. The concentration of the solute (sodium chlorid) and the Δ at the threshold point, that is the point at which the fluid balance just ceases to be in favor of the colon, shows a striking constancy in a long series of experiments. There is evidence that increased blood chlorids may effect this threshold value.

Id.—Solutions of sodium chlorid above or below blood level come into a chlorid partial pressure equilibrium with the blood. Increase of blood chlorids affects this equilibrium. There is an attempt at total osmotic pressure equilibrium between the colon contents and the blood. Evidence is at hand which indicates the other blood constituents diffuse into sodium chlorid solutions in the colon. This is more apparent as the concentration of the solution approaches the level of the blood chlorids.

Id.—The colon behaves toward solutions of sodium sulphate essentially like a semipermeable membrane. Water is absorbed from hypotonic solutions, and the increases to blood level. With hypertonic solutions the volume increases, the concentration decreases and the Δ approaches blood level. Solutions of concentration nearly iso-osmotic with the blood show little change in volume and the Δ closely approximates that of the blood. Hence, there is free passage of water with pracically no diffusion of sulphae. The deficit of sodium sulphate is very small and bears no constant relationship to the total amount of sodium sulphate introduced, nor is it dependent on the length of stay in the colon, and therefore seems to be due to adsorption rather than to diffusion. Magnesium sulphate shows even less absorption from the colon than sodium sulphate. The failure of absorption of these salts from the colon emphasizes the specific importance of the large intestine in saline cathasis.

Id.—When sodium sulphate or magnesium sulphate is added to solutions of sodium chlorid and introduced into the colon, the concentration of chlorids diminishes rapidly and the amount present approaches a zero point. The concentration of sodium or magnesium sulphate approaches a value of a concentration equi-osmotic with the blood. The final Δ of the solution approximates that of the blood. Less chlorids diffuse into weak solutions of sodium sulphate than into distilled water and this amount decreases with increasing concentration of sodium sulphate. Sodium sulphate speeds the rate of absorption of sodium chlorid through the colon wall when the two are introduced simultaneously. This increases with increasing concentration of the sulphate. It occurs in hypotonic as well as in hypertonic solutions. After sodium sulphate has been present in the intestine the subsequent absorption of sodium chlorid and water to some extent increases. It is never decreased. Other factors such as mechanical washing, introduction of various strengths of sodium chlorid, notably distilled water, do not affect the subsequent absorption of sodium chlorid or fluid in the colon. Analogies of the effect of sodium sulphate on chlorid, in other parts of the body, are presented from the literature.

Id.—Calcium lactate in increasing concentrations first accelerates, then inhibits the absorption of chlorids from solutions of sodium chlorid in the colon. There is an indication that this action bears a relationship to the ratio of calcium to chlorine. The first stage of the action of calcium lactate on sodium chlorid resembles that of sodium sulphate on the salt. The last stage presents the opposite effect to that of sodium sulphate.

Blood Diastase and Placental Function.—When the blood vessels of the kidneys are tied or when nephritis is caused by the injection of uranium, a retention of diastase in the maternal blood is produced and there is an increase of diastase in the fetal blood. In the case of nephritis after the injection of uranium, there is no change in the quantity of diastase in the amniotic liquid. When takadiastase and pure glucose are injected simultaneously into the vein, blood sugar increases both in the maternal and fetal bodies, but no change is produced in the amniotic liquid and there is no change in the diastase of the maternal blood, but we find a little increase of it in the fetus and in the amniotic liquid. From the above facts the authors conclude that the placenta is permeable to the diastase ferment. They do not explain the reason why the diastase ferment passes into the amniotic liquid while sugar does not. In the case of the parenteral injection of a ferment it is lost in the animal body, which seems to be due not to the toxic influence of the ferment or to the regulation of the placenta, but to the regulating function of some other part of the body. As regards the origin of the amniotic liquid, there are many complicated relations, and it is difficult to explain it by the simple results of the present experiments.

Antineuritic Vitamin in Wheat and Corn Kernel.—According to Voegtlin and Myers the germ or embryo of the wheat and corn kernel contains all of the antineuritic vitamin of these cereals. Wheat flour or corn meal containing the germ is, therefore more nutritious than the corresponding highly milled products. Consideration of the distribution of the antineuritic substance in the wheat and corn kernel and in the animal body suggest that this accessory food is necessary for the metabolism of the growing plant as well as the animal body. It appears that cells with an especially active metabolism are also rich in antineuritic vitamin.

Cerebrospinal Fluid Pressure.—Weed and McKibben claim that intravenous injections of Ringer's solution cause no lasting change in the pressure of the cerebrospinal fluid. Intravenous injections of hypotonic solutions (distilled water) are followed by a marked and sustained rise in the pressure of the cerebrospinal fluid. Intravenous injections of hypertonic solutions (concentrated sodium chlorid, sodium bicarbonate, sodium sulphate and glucose) cause initial rise in the pressure of the cerebrospinal fluid followed immediately by marked fall in this pressure, often to below zero.

*Complications of Influenza from Roentgenologic Standpoint. R. H. Boggs, Pittsburgh.—p. 239.
Caldwell Portable Roentgen-Ray Outfit. C. N. Moore, Schenectady.—p. 243.

Roentgen-Ray Study of Epidemic Influenza and Bronchopneumonia.—Twenty-eight cases of influenza and pulmonary congestion were studied by Honeij by serial roentgenography. The examinations varied in number from one to ten. In the case of influenzas and congestions these examinations often were taken every day while the bronchial changes progressed, until the patient recovered, or until a pneumonic process developed, examination being less frequent after a definite diagnosis of the process was made. In the case of a pneumonia being diagnosed on first examination, repeated examinations were then made to determine the progress of the disease until the final stage had been reached. A detailed report is given of the findings in these cases.

Complications of Influenza from Roentgenologic Standpoint.—According to Boggs the roentgen rays as a means of diagnosing and recording the changes in the lungs and pleura are not directly diagnostic; but when compared with inspection, palpation, percussion and auscultation they yield much more accurate information than can be obtained by physical signs alone. It is a more accurate method than percussion alone, because even deep percussion is not accurate more than 2½ inches below the surface, and the density in the lungs and pleura can be compared better with the normal surrounding or adjacent organs and tissue. Stereoscopic plates taken anteriorly and posteriorly show the density and thickness of a pneumonic lung or a layer of fluid in the pleural cavity. By knowing the thickness and density of the pathologic lesion in the lung or pleura, or both together, with its position, one can usually tell what kind of breathing is heard by the stethoscope. The fluoroscope is a valuable aid to the roentgenologist for chest examinations in showing that much of the function of the lungs is disturbed by the pulmonary disease; but it cannot take the place of a good pair of stereoscopic plates taken posteriorly and anteriorly.

Influenza and Streptococcus Hemolyticus.—In the laboratory of General Hospital No. 14 there came up the question of what could be the cause of a number of undiagnosed pyrexias, which ran a course of a few days and then dropped down to normal and stayed normal. With the temperature there was also a slight irritation of the throat. The bacillus "influenza" was present in great quantities in case after case. A majority of men operated on for appendicitis acquired a primary infection of streptococcus. One set of cultures proved to be valuable, and that was a set made from the wall of one of the operating rooms. It contained *Streptococcus hemolyticus*. The habit in that hospital was to have a number of adhesive plasters cut and stuck to the wall of the operating room. After the patient was operated on, sterile pads were put on the wound and the strips of adhesive plaster from the wall were put on to hold the dressing. It was concluded that the infection was introduced by the adhesive plaster from the wall. The walls were washed and repainted and the habit of sticking adhesive strips to them was stopped. The almost postoperative epidemic ceased.

Chronic Septic Inflammation in Bone Following Gunshot Wound.—In the presence of nonunion, the fact that the wound is septic, Gallie says, is not a contraindication to active treatment of the fracture as well as of the osteomyelitis. Gratifying results may be anticipated from thorough freshening of the ends and adjusting of the fragments, providing efficient drainage is secured. The best time to correct malunion in septic cases is at the time of the operation for the cure of the disease in the bone.

Tuberculosis as Causative Factor in Disordered Action of Heart.—The subcutaneous tuberculin test was done by seven medical officers in 300 unselected cases of disordered action of the heart and the results are reported by MacIntyre. Positive reactions were obtained in thirty-two cases; negative reactions in 268 cases and local reactions only in ninety-seven cases.

Comparison of Wassermann Tests.—One hundred and seventeen serums in all were tested by Thomas and Simon, the two tests being performed side by side with the same gross complement, amboceptor and washed sheep's corpuscles; all serums were inactivated at the same time and the tests performed under similar conditions of temperature and pressure, in this way eliminating sources of error as much as possible. Ninety serums gave negative reactions with both methods. Twenty serums gave a strongly positive reaction, i. e., complete inhibition of hemolysis with clear supernatant fluid in both tests, and in no case did a serum give a strongly positive reaction with Kolmer's method and not so in the test as described in No. 4 standard method. In only one case was a serum slightly positive or doubtful in one and negative in the other. In no case was there marked divergence in the results; in only four out of 120 cases was there a slight difference in the readings of the two methods. In long treated cases serums tested by No. 4 method give a more delicate reaction. The authors believe that the varying number of units of complement used in No. 4 method tend to eliminate sources of error by nonspecific complement fixation.

Postmortem Findings and Bacteriologic Examination of Influenzal Pneumonia.—A small gram-positive diplococcus was found by Little in the lung sixty-two times, in the spleen nine times and in the heart's blood twenty-three times. It was the predominating organism, and is regarded by the author as of etiologic significance, especially in pneumonia supervening on influenza. He suggests that it is probable that the initial infection of the upper air passages is due to the *B. influenzae*, and the graver complications are due to the small gram-positive diplococcus as an intermediate type between the pneumococcus and streptococcus. It differs from both in animal experimental inoculations. It did not agglutinate the three types of pneumococcus serum in a higher dilution than 1 in 10. It was the only organism found in pure culture. Little is satisfied from animal experiments that a vaccine prepared from it proves of prophylactic value. There was no systemic effect; there was, however, a slight local reaction at the site of inoculation.

Roentgen-Ray Examination of Liver in Arsenic Poisoning and Jaundice.—The angle formed by the junction of the liver and vertebral shadows on the right side is usually a right angle. Less frequently it is an obtuse angle. Nine of ten cases of acute liver atrophy examined by Strathy and Gilchrist showed the upper surface of the liver more dome shaped than normal and the liver vertebral angle an acute angle. The atrophy of the liver was due to arsenic poisoning in seven of the cases and to catarrhal jaundice in the other three. In the leftsided pleural effusions and marked cardiac hypertrophy the liver vertebral angle tends to be somewhat acute, but the shadow of the liver is not more dome shaped than normal. The angle in these cases is due to pressure on the left lobe of the liver slightly tilting the organ.

Nephritis in Returned Soldiers.—McCordick and Robbins analyzed 2,400 records of returned soldiers. In only seventeen instances was there no record of any urinary examination. There were eighty-seven cases of nephritis in only three of which was the nephritis a definite complication of other conditions (tuberculosis and syphilis). A preexisting nephritis was suspected from the history in seven cases. Nine men had seen service only in England, never having gone to France. Sixty-eight soldiers had seen active service in France. These sixty-eight cases were definite cases of so-called trench, or war nephritis. According to the authors this so-called "war nephritis" is mild in type; runs an inoffensive course; produces no serious cardiovascular changes; does not destroy kidney structure to any extent; and 50 per cent. of the cases, at least, progress favorably to a cure.

Anomaly of Fundus Oculi.—On examining the right fundus of a soldier, the picture seen by McKee was as follows: At the area of the optic disk instead of the disk was a rectangular pearly white membrane, attached by bands to the retina at each coroner except at the superior temporal. This membrane hung in front of the retina like a curtain. It was a good deal larger than the normal optic disk, and at the superior temporal corner slightly more than 1 millimeter from the underlying retina. On the superior border the artery ran along to the temporal part with numerous branches extending to the area above. To the nasal side and below the vessels were also profuse. About this membrane there were seen pigmentary changes denoting almost a complete rupture of the choroid. There were also one or two areas of displaced pigment in other parts of the retina.

*Case of Atypical Scabies. D. W. Montgomery, San Francisco.—p. 317.
Clinical Types of Lichen Planus. J. A. Fordyce and G. M. MacKee, New York.—p. 320.

Eczema in Infants.—The type of infantile eczema which Ravitch and Steinberg think is due to disturbed thyroid secretion does not differ much from other infantile eczemas, except that it is always a dry eczema. The skin is harsh and rough; there may be sweating but no fatty or oily secretion seems to be present. The treatment consists in the administration of iodin, iodid or thyroid gland.

Atypical Scabies.—Montgomery's patient had a minutely vesicular eruption on the sides of the fingers, some scratch lesions on the arms and in the axilla, a finely granular crusted eruption in the supramental groove, which, with the lens, was seen to be also minutely vesicular, and an intense, generalized, sleep-robbing pruritus. The vesiculation on the fingers and face recalled a plant poisoning but the patient denied exposure. Scabies was next considered, but there was no pustulation. There were no lesions between the fingers nor on the front of the wrists, nor on the immediately adjacent portion of the palms which are so frequently affected. The axillae were itchy, but almost entirely free of eruption. The nipples were also itchy, but did not even look irritated. No other member of the family suffered from the same complaint. The lesion on the thumb was examined microscopically in glycerin, and the cuniculus provided with acarus eggs and feces was easily demonstrated. The diagnosis of scabies was fixed beyond a doubt.

Case of Lethargic Encephalitis. J. F. Shaw, F. H. Bartlett, Fairfield.—p. 284.

Endermic Vaccination Against Smallpox.—This method was used exclusively in 280 vaccinations at the Maine School for Feebleminded with satisfactory results. Of the 280 vaccinations, 174, or 62.11 per cent., were successful. Of the 106 failures, eighty-two, or 29.27 per cent., had typical scars resulting from previous vaccinations. One of the failures had smallpox some years ago. Twenty-three, or 8.21 per cent., had never been vaccinated successfully before and failed on this occasion. Only thirty-six, or 12.85 per cent., among 174 successes had scars. In Walsh's opinion the endermic method of vaccination is the best of all the methods. The comparative freedom from complications is apparently a marked feature of this method.

"Filter-Passing" Virus in Certain Diseases.—Bradford claims that Koch's postulates have been fulfilled in six maladies, polyneuritis, lethargic encephalitis (or encephalitis more broadly), trench fever, influenza, nephritis and rabies. In a considerably larger group only the bacteriologic evidence of the obtaining by culture of a virus is reported. These maladies are: mumps, measles, rose measles, typhus, scarlet fever, hemorrhagic chickenpox and vaccinia.

Bacteriology of Certain Filter-Passing Organisms.—Wilson describes the technic followed in studying these organisms found in polyneuritis, encephalitis, influenza, trench fever, nephritis and rabies.

Ulceromembranous Laryngitis of Streptococcic Origin.—Fifty cases are analyzed by Hemmeon. Out of fifty cultures, thirty-five showed streptococci in almost pure growth; ten showed the same as the prevailing organism, and the remainder were indefinite. Of the thirty-five streptococcic growths, twenty-five were classified as *Streptococcus hemolyticus* and ten were *S. viridans*. Further subdivision of these groups was not attempted.

Rôle of Sympathetic Nervous System in Disease.—Brown contends that the stimulation of the sympathetic and of its coadjutors, the suprarenals and thyroid, means the spending of reserves in the supreme struggle for survival. The quickening of all the vital processes may produce, for all time, a feeling of exaltation and well being. This may be regarded as a physiologic justification for Nietsche's injunction to live dangerously. But exhaustion lies in wait if the struggle is unduly prolonged. A vicious circle is the pathologic equivalent of a prolonged struggle. Next, under physiologic conditions the sympathetic acts as a whole, while one of the phenomena of disease is dissociation. Sensory dissociation is seen, for instance, in tabes and syringomyelia. Sympathetic dissociation may play a part in diabetes and in disorders of digestion and circulation. The general plan of the sympathetic and its general action in assisting the struggle for existence is discussed. Evolved in a subconscious plane, it remains forever beyond the control of the will. The higher centers of the brain show their influence on the lower chiefly in the direction of inhibition. Brown says that the highest organism is the most self-controlled, but the sympathetic cannot be thus controlled. Though we may deaden the emotion, we cannot prevent the response to an emotion once evoked. To regulate this we must trust to reserves, inherited and maintained through generations of stable and equable ancestors. "We might modify the dictum that this war will be won by the nation with the strongest nerves, and say it will be won by the nation with the strongest adrenals, for just as character is revealed in the instinctive response which occurs quicker than thought, so the powers of tenacity and endurance may be foreshadowed in the original emotional response."

Action of Flavine and Its Derivatives.—Experiments were made by Tubby and others to determine the minimum lethal dose of proflavine and acriflavine for cats. All injections were made into the external jugular vein under ether or chloroform anesthesia. The effects were largely dependent on the rate of injection. Rapid injection usually produced respiratory failure, the heart continuing to beat. The animal could usually be revived by artificial respiration. The agglutination effect could be reduced to a minimum by giving the injections very slowly. Deep yellow staining of the mucous membranes is produced by the larger doses. It appears within a few minutes, is marked for twenty-four hours, and then fades slowly. As the result of numerous experiments,

The Sympathetic Syndrome.—Ramond and Carrié analyze the symptoms liable to be induced when the sympathetic nervous system is suffering from the action of some poison or other irritation or from inadequate nourishment. The resulting tremor, emotive instability and puffy face are sometimes mistaken for alcoholism or for "emotional nervousness," or the subjects are supposed to have heart disease on account of their tachycardia; or dyspepsia from their disturbances after eating, or an abortive type of exophthalmic goiter is assumed. The tachycardia is not a tachycardia from exertion, and this distinguishes it from actual organic disease of the heart and the tachycardia of convalescence and that with high blood pressure. The tachycardia of the sympathetic syndrome is more like the *névrose tachycardique* to which Gallavardin has recently been calling attention. Only when the most painstaking examination has failed to reveal any local cause for irritation of the sympathetic nerve at any point, are we justified in assuming some general cause, and applying merely general sedative measures, rest, hydrotherapy and other means to soothe the nervous system.

Aerobic Microbian Associations in Influenza.—Richet and Barbier relate that the sputum of their influenza patients contained most frequently the Pfeiffer bacillus associated with the catarrhalis. Next in order of frequency was the association of the Pfeiffer and the pneumococcus, and third in the list, the symbiosis of all three. The Pfeiffer-catarrhalis gave a grave prognosis, and the infections with streptococci always proved fatal. The presence of the pneumococcus did not seem to render the prognosis any graver than with the Pfeiffer-catarrhalis alone. The action of metal salts seemed most pronounced in the pneumococcus cases. A fixation abscess seemed to promote the cure in some of the pneumococcus cases. In conclusion they remark that it may be well to combat these mixed infections by injecting the patient with several of the specific antiserums.

Hemorrhagic Spirochetosis.—Pagniez prefers the term *spirochetose ictérigène*, as the hemorrhagic form is not so much in evidence in France as in Japan. Only in twenty-two of his forty-three cases of this spirochetosis was there any tendency to hemorrhage, and in these cases it took the form of recurring epistaxis, but these were always the severer forms. The blood picture in these graver cases and often in the milder ones showed always a considerable reduction in the number of blood platelets and an exceptionally long coagulation time. This great reduction in the platelet content was evident from the very first, and was independent of the jaundice. This drop in the platelet count is a valuable aid for the differential diagnosis in incipient and dubious cases. The platelets may drop to nine-tenths of the normal number or even below. The red and white cells do not show any such drop in numbers; there is often actual leukocytosis. The platelets finally return to the normal figure, but this may take two or three weeks. Pagniez has not been able to detect a drop in the blood platelets in any other of the principal infectious diseases, such as the eruptive fevers, pneumonia or erysipelas. In typhoid there is a reduction, but it is far from that with this spirochetosis. Only in certain cases of purpura and in pernicious anemia is anything comparable observed, and in these the drop in blood platelets is permanent. He published in 1912 a case of hemorrhagic purpura with complete disappearance of all the platelets from the blood. In the spirochetosis in question, the nonretraction of the clot and the drop in the blood platelets were constant, but not all the cases presented hemorrhage. This suggests that other factors than these are involved in the hemorrhages.

The Feeble Pulse in Idiots.—Laroche and Richard have been impressed with the microsphygmia which seems to be almost the rule in the inmates of a certain asylum for feebleminded where they have been conducting research on the endocrine system in idiots. They theorize to explain the mechanism and causes of the hypertony of the sympathetic nervous system which seems to be responsible for the microsphygmia.

*Scurvy in Infants. J. Comby.—p. 225. Cont'n.
*Walled-Off Meningitis in Infants. R. Marcland.—p. 251.
Congenital Myxedema. G. Schreiber.—p. 256.
*Lethargic Encephalitis. J. Comby.—p. 259.

Scurvy in Infants.—Comby now has a record of sixty cases of Barlow's disease in infants. In all but two there was a painful pseudoparalysis and in forty-six there were ecchymoses on the gums; those infants without the latter were always too young to have had any teeth appear. There were signs of rachitis in about 50 per cent. The symptoms from the scurvy had been ascribed to everything but the right cause in the overwhelming majority of the cases. He cites a case reported by Rotch in which three surgical operations had been made on the infant before the scurvy had been recognized. A common blunder is to ascribe the symptoms to inherited syphilis alone. Burckhardt relates that in the case of one infant of 11 months the diagnosis wavered only between osteomyelitis and sarcoma of the femur. Puncture brought blood and the femur had fractured, but prompt recovery followed when treatment for scurvy was tentatively applied.

Walled-Off Meningitis.—Marcland expatiates on the cure of an infant of 4 months with severe meningitis and visual disturbances from the pyohydrocephalus. This makes the fifth case of the kind on record, he says, in which recovery followed injection of the meningococcus antiserum directly into both ventricles. The pocketing of the process and the stasis were favored by the long intervals between the intraspinal injections, the child living on a remote farm.

Lethargic Encephalitis.—Comby has compiled the prevailing views on this disease.

Bulletin de l'Académie de Médecine, Paris

April 29, 1919, **81**, No. 17

*Compulsory Notification of Tuberculosis. Hayem and others.—p. 516.
*Therapeutics Judged by Figures. L. Grimbert.—p. 540.
*Unrecognized Amebic Dysentery. M. Labbé.—p. 550.
Alleged Solutions of Mercury Benzoate. M. Delépine.—p. 552.
*Health of Schoolchildren in the Regions Occupied by the Germans. J. Genevrier and G. Heuyer.—p. 553.
*Serotherapy of War Wounds. P. Bouchet.—p. 556..

Declaration of Tuberculosis.—The various medical societies of France have been discussing the feasibility and advantages of introducing compulsory notification of tuberculosis. The Académie has devoted a major part of each meeting recently to discussion pro and con, and the larger part of the *Bulletin* for several weeks has been filled with the reports of the discussions. The resolutions voted were given in the Paris Letter, p. 1781.

Therapeutics Judged by Figures of Amounts Used.—Grimbert adds another ten year report to those that were published in previous decades dealing with the drugs used in the public hospitals of Paris. These reports show the trend of the times in therapeutics. During the last decade there has been a constant decline in the use of antiseptics, iodids, bromids, hydrogen dioxid, glycerin, arsphenamin and cod liver oil. The drugs showing a constant upward trend include neo-arsphenamin, tincture of iodin and hexamethylenamin. The lactic ferments, organ extracts for injection, and certain colloidal metals are still on trial.

Blunders with Amebic Dysentery.—Labbé refers to cases of amebic dysentery which are mistaken for some other form of enteritis as they present an atypical course. Some of the persons affected had never been out of France or even out of Paris. There may never have been actual dysentery, and only the discovery of the ameba in the stools cleared up the cause of the chronic enteritis of up to twenty years' standing.

Health of Schoolchildren in Occupied Regions.—Genevrier has been visiting Lille and the other cities in the *régions libérées*, on behalf of the Ligue d'hygiène scolaire. He reports that the results of four years of undernourishment and overwork demand immediate relief for the schoolchildren. See Paris Letter, p. 1558.

Polyvalent Serotherapy in Wounds.—Bouchet emphasizes the importance of a polyvalent antiserum in treatment of wounds and other injuries in war and in peace. He urges its use in traumatic shock, in septicemic conditions, in traumatic infectious processes and industrial accidents. The antiserum with which he has been working is that made by Leclainche and Vallée. In 420 war cases the traumatic shock became much attenuated after injection of the antiserum. In seventeen cases of hemophilia it had a decidedly favorable action, as also in large numbers of ordinary peace injuries.

Streptococci in Influenza Sputum. J. Lochelongue.—p. 79.
Causative Agent of Trench Fever, Influenza and Nephritis. A. Bernard.—p. 79.

The Nature of Cancer.—Audrain comments on the resemblance between the action of the cancer cell and that of the syncytium cell. The latter also destroys all before it until it reaches the vessels in the ovum, and thus brings the young vessels into the pools of blood. But it stops when this is accomplished, whereas the cancer cell keeps on. Audrain suggests that when the cells of the organism are kept in a state of abnormal excitation, it is easy to conceive that after some trauma certain cells may start on a destructive course, like that of the syncytium and, escaping from control, develop cancer. Syphilis seems to keep the tissues in a state of abnormal excitation, and hence this may be a factor in malignant disease although possibly not until the third and fourth generation. He asks in conclusion whether some abnormal general or local superactivity cannot be determined as having long preceded the development of the cancer.

Elimination of Procain Injected Intraspinally.—In twelve of the fifteen cases studied by Achard the procain was eliminated between the second and third hours, and had all been recovered by the sixth hour. The maximum was always at the second hour. The cases in which the elimination proceeded more slowly were the only ones presenting headache.

Revue Médicale de la Suisse Romande, Geneva

March, 1919, 39, No. 3

*Laws on Building and Sanitary Inspection. E. Olivier.—p. 97.
*Undernourishment and Famine Edema. R. Guillermin and F. Guyot. —p. 115.
Dysentery in Southern Switzerland. M. Chapuit.—p. 120.
*Recovery from Multiple Tuberculosis. R. Burnand.—p. 127.

Ordinances on Building and Building Inspection.—Olivier discusses the proposed revision of the legislation on this subject, saying that the principle to be followed is that the rights of property are always subordinate to the rights of life.

Undernourishment and Famine Edema.—Guillermin and Guyot remark "Every physician now and then encounters a case of inanition; it may be an insane person, a cancer patient, a hysteric (or a suffragette) suffering from complete exhaustion from lack of food, but never, until 1915, would any physician have imagined that in the twentieth century he would ever behold the spectacle of famine ravaging whole populations, recalling the famous plagues of Egypt and the lamentable pictures described by our ancestors." Even in Switzerland physicians have noticed a general reduction in the weight of their clients, and the lesser proportion of cases of obesity. The scarcity of sugar and fats is mainly responsible for this. It recalls Erb's saying that with a course at Carlsbad in treatment of obesity, the fact that the meals are served à la carte, in extremely small portions, and at a very high price, explains the benefit from the stay there at least as much as the waters. They describe some cases of "famine edema" in French prisoners of war seen at Berlin and elsewhere, saying, "It suggested the clinical picture of a cardiac lesion with failing compensation. It affected mainly men who had to do heavy work on a ration of from 800 to 1,200 calories. These calories are drowned in food containing 15 per cent. and more of indigestible cellulose, with very little fat and a maximum of 50 gm. of albumin per day. The dropsy, anemia, apathy, muscular weakness and nervous exhaustion were associated with the *facies pestica*." Dogs are said to die when they lose 40 or 50 per cent. of their weight, but with the famine edema a loss of 40 per cent. was common. Digitalis has no influence on this edema. The number of fatal cases in Poland and elsewhere in which no tendency to scurvy was noted seems to indicate that it is a distinct morbid entity.

Recovery from Pulmonary Plus Intestinal Tuberculosis.—Burnand says that the case here reported teaches that in tuberculosis one must never give up hope, and that one may venture even quite hazardous operations when the patient is otherwise doomed. This patient was a woman of 27, and the pulmonary lesion seemed to be arrested by an artificial pneumothorax kept up for twenty-six months. The ten ulcerations found on the large intestine were excluded from the intestinal tract by severing the ileum 20 cm. from the valve of Bauhin, and reinserting it in the lower portion of the descending colon. After the laparotomy all the symptoms subsided and three years and a half passed with apparently perfectly restored health. Then came an intercurrent gastric fever and she wrote to Burnand that she had begun to cough and expectorate profusely and had fever and hemoptysis. He telegraphed her to return to his care at Leysin for another course of treatment. A large cavity was evident in the outer part of the right lower lobe and the pulse was bad. Several attempts to induce pneumothorax failed, while the general toxic condition was growing constantly worse during the two or three months while sanatorium treatment was vigorously applied. Then nine ribs were resected through an incision parallel to the spine, from 8 to 15 cm. being cut from each rib, under general anesthesia, with the aid of the pulmotor. The fever subsided almost immediately, and in three months no further tubercle bacilli were to be found, and at date of writing, eleven months later, the patient shows all the appearances of a clinical cure. Burnand ascribes the success of the plastic operation to the fact that the cavity was a grave localized suppurating lesion rather than a focus in full evolution.

April 3, 1919, 40, No. 27

*Complications of Influenza. F. Bindi.—p. 234.

Complications of Influenza.—Bindi describes both medical and surgical complications as he encountered them, including empyema, of which he has had 13 cases. Five of the patients died, including one with what seemed to be a metastatic peritonitis. All recovered in 10 operative cases of mastoiditis; one was in a child of 4. There were 3 cases of suppurating and 2 of nonsuppurating parotitis. Among the medical complications was a case of ulnar paralysis, one of paraplegia, and some of melancholia with ideas of persecution.

Recent Literature on Traumatic Proliferation of Adipose Tissue in Knee. E. Aievoli.—p. 318.
Recent Literature on Cholesterol in the Blood. G. Moscati.—p. 319.

Course of Typhoid in the Vaccinated.—Pezzi reports that at Milan during 1917 the mortality among hundreds of soldiers with the typhoid bacilli found in the blood was 23.4 per cent. among those who had been given antityphoid vaccination while in the unvaccinated it was 27.8 per cent. In 1918 the corresponding figures were 18.5 and 14.7 per cent.

The death rate was thus slightly higher in the vaccinated over the two years. In one group of 124 vaccinated, 10 per cent. had relapses and only 2 per cent. in 104 nonvaccinated. The total mortality in the 438 cases of typhoid or paratyphoid or both together was 18 per cent. in the unvaccinated; 10.8 in the vaccinated. In the larger sense of typhoid plus paratyphoid, the mortality was reduced by the vaccination.

*Cytotoxic Serums and Tumors. P. Sisto.—p. 253.
*Experimental Tumors of the Brain. D. B. Roncali.—p. 269. Cont'n.
*Cancer of the Stomach. G. Perez.—p. 298.

Action of Cytotoxic Serums on Development of Tumors.—Sisto reports experiments on white mice inoculated with cancer after or at the same time with subcutaneous injection of a cytotoxic serum. The latter was obtained from rabbits that had been treated by intravenous injection of fresh spleen, testicle or liver tissue (triturated in saline) to produce a cytotoxic serum. The spleen-cytotoxic serum showed a pronounced action, the tumor grafts taking root and flourishing exceptionally well in these animals. This seems to indicate that one of the functions of the spleen is to protect against malignant growths. Brancati and Korentschewsky have reported experiments showing that an acquired immunity to tumors was lost after removal of the spleen. This was confirmed in Sisto's mice. Serafini has also reported similar experiences after ligation of the splenic blood vessels. Sisto reports further that liver-cytotoxic serum has a favoring action on tumor growth, while testicle-cytotoxic serum distinctly checked or prevented the growth of the malignant tumor cells. A large number of charts show the findings at different intervals.

Experimental Brain Tumor.—Roncali has published a large number of articles on the parasitic origin of cancer, and now reports that he has succeeded in inducing experimental gliofibro-endotheliomas in the brain. He offers this as a further contribution to the parasitic origin of carcinomatous growths. He introduced the endotoxins and exotoxins of blastomycetes inside the skull of twelve dogs. Actual carcinomas developed in consequence in the first group of five dogs, as he shows by the microscopic findings. In conclusion he emphasizes that the elements of cancer tissue represent at first merely a defensive reaction, but their biochemistry becomes so modified in their struggle for existence with the parasites that they acquire the properties of a parasite and take root anew wherever they may land. He is director of the Instituto di Patologia Speciale Chirurgica of the University of Padua.

Resection of Stomach for Cancer.—Perez reports the ultimate outcome in 12 patients of 20 given operative treatment in 1913-1914 for gastric cancer. There was nothing to suggest syphilis in more than 2 and alcohol could be incriminated only in 3. In the majority there was a history of chronic gastric disturbance, suspicious of gastric ulcer in some cases, polyposis in one, but in no case was there a history of trauma. The father of one woman had died of gastric cancer and the mother of one man of esophageal cancer; in 2 others there was a family history of gastric ulcer. He gives a minute study of the anatomic lesions found as compared with the symptoms, the functioning of the stomach, the radioscopic findings and the ultimate outcome. The results of his extensive resection were very encouraging. Even those in advanced cachexia bore the operation well. One of the patients succumbed to pneumonia, which is the most to be dreaded of all operative complications. One woman in profound cachexia seems in ruddy health now, a year later. A palliative gastro-enterostomy in inoperable cases may be followed by quite long survival as some cancers are very slow in growth.

Brazil-Medico, Rio de Janeiro

*To Correct Retrodeviation of the Uterus. J. Adeodato.—p. 89.

Ligamentary Hysteropexy.—Adeodato declares that the Alquio-Alexander-Adam operation by way of the inguinal canal is not surpassed by any other technic from the anatomic and physiologic standpoint. But when the uterus requires operative measures to bring it into its normal position, the shortening of the ligaments is best done through an abdominal incision. For this, he endorses a modification of Gilliam's method which avoids the danger of possible ileus that is liable with the Gilliam (or Doléris) technic. It occurred in one of his cases nine days after the operation. A loop of intestine had slipped down into the pocket formed in front of the uterus by the round ligament sutured to the aponeurosis of the rectus muscle in the Gilliam operation. The operation otherwise always gives ideal results. To avoid this drawback, he fastens the vertex of the loop of the round ligament not to the median line but to the side of it, striving to keep the fundus of the uterus apart from the incision in the peritoneum, to prevent development of adhesions. If the angle of flexion will not yield to this moderate shortening of the ligaments, he prefers to supplement it with an operation on the isthmus rather than to bring up the fundus too close to the sutured incision in the peritoneum. Local and general treatment before and after the operation is necessary to free the patient from all her chronic disturbances from retrodeviation.

Teething.—Suñer reiterates that the teething period in infants is not pathologic but is a period of stress and adjustment, like puberty and the menopause. Inherited taints may first make themselves manifest at such periods, and various pathologic conditions otherwise may prove refractory to all treatment until the stress of this critical epoch is somewhat mitigated.

Radium Treatment of Superficial Cancer.—Sierra relates that he has realized a complete cure in the last eight years in all but three of the more than 100 cases of epithelioma of the skin in which he has applied radium treatment. The three refractory cases had been previously given roentgen treatment and had had a radiodermatitis. He gives the details of a few typical cases, and warns that roentgen treatment may aggravate the cancer, and it is then extremely difficult to arrest its course.

Radiologic Diagnosis of Gastric Cancer.—Guillén gives a number of colored illustrations showing the interpretation of the various roentgen findings.

Bullet in Parietal Lobe.—Albo relates that the hemiparesis and dysarthria subsided after removal of the bullet from the left parietal lobe under roentgen control. The case is illustrated.

Association of Ameba and Trichomonas. Barlaro and Mujica.—p. 298.
Nerve Elements in Auriculoventricular Bundle. P. Rojas.—p. 299.

The Schick Reaction.—De Elizalde applied the Schick test to 673 children in an asylum and to 221 in a children's hospital and compares the findings with those reported by Kolmer and others in The Journal. He classifies the reaction by ages, commenting on the negative reaction in very young infants as evidently due to the infants' sharing the mothers' immunity. This transmitted immunity is gradually lost, so that by the age of 3 the maximum of reaction is obtained. After 3, natural immunity is acquired so that only from 5 to 15 per cent. of adults give a positive response to the Schick test. The reliability of the test is confirmed by the experience that in the whooping-cough ward 15 of the children gave a positive reaction and the other 23 showed no response. Diphtheria was imported into the ward but only 5 of the children contracted it and these were all in the positive group. His experiences confirm the harmlessness of the Schick test, and also the absolute independence of the reaction from the condition of the general health. The presence of other acute or chronic infectious diseases does not seem to modify the reaction.

Tuberculin Test for Recruits.—López has adopted Vitón's method of extremely minute doses of tuberculin in testing for and treating pulmonary tuberculosis in recruits, and lauds the fine results obtained. It is possible by this means to weed out the tuberculous new arrivals, and to cure many of the soldiers. (Vitón's extremely minute doses were described in these columns recently, page 1581.) López insists that this method of ultra small doses of tuberculin at four day intervals can be applied by any practitioner and the results to date have nearly always surpassed all anticipations.

*Trench Fever. A. Piga and L. Lamas.—p. 49.
*Reconstruction of the Face. A. Cortés Lladó.—p. 64.
*Eclampsia and Evacuation of the Uterus. Vital Aza.—p. 89.
*Syphiloma of the Eyelids. F. Couce and F. Poyales.—p. 92.

Trench Fever.—Piga and Lamas review the various publications on trench fever (Wolhynia fever, five day fever) and emphasize that it may appear elsewhere than in the trenches, and that physicians should be on the alert to recognize it. They do not regard the means of transmission of the disease as having been definitely ascertained although transmission by lice is most probable. Treatment to date can be only symptomatic.

Reconstruction of the Face.—Lladó's twenty-five illustrations show the guiding principles in treatment of deformity resulting from war or other wounds of the face. He describes the French, Italian and other methods of plastic facial surgery, specifying the class of indications for each. He studied the methods directly in the hospitals in France and elsewhere.

Eclampsia and Evacuation of the Uterus.—Aza remarks that evacuation of the uterus removes the source of the toxins but does not suppress the toxins circulating in the body fluids and the toxins fastened in the tissues. Hence evacuating the uterus is not certain to arrest the convulsions. The convulsions may even develop for the first time after delivery, or the woman may die after delivery before the convulsions have had time to develop. When the practitioner is confronted with a case of eclampsia in a woman on the point of being delivered, he should of course hasten delivery if the cervix is sufficiently dilated. But the general practitioner, in the home, is not able always to do cesarean section at a moment's notice, and the injury to both mother and child from forcible extraction through the imperfectly dilated cervix is such that the remedy is worse than the disease. Hence Aza insists that the practitioner should sometimes concentrate his efforts on medical measures, venesection, morphin, etc. He should not attempt surgical measures unless they can be rapid and harmless.

Syphilitic Lesions in the Eyelids.—A large color photograph reproduces the tertiary syphilitic lesion of the inner angle of both eyes, an actual syphiloma in the right eye. The man of 40 has two healthy children; the primary chancre was acquired at 30 and given a course of mercurial treatment. There had been no other signs of syphilis until these lesions in the eyelids developed.

*Umbilical Hernia. J. M. Montoya.—p. 338.
The Vitamins. E. Gómez.—p. 348.
*Syphilis of the Nervous System. E. Campo.—p. 364.

Umbilical Hernia.—Montoya discusses umbilical hernia in children, saying that it is more common than inguinal hernia but, owing to the tendency to a spontaneous cure, it seldom reaches the surgeon. He has operated in thirty-two cases in the last six years. He found in one cadaver that the intestines had formed a hernia into the cord at birth; in such a case the bowel should be reduced at once and the cord ligated. For ordinary umbilical hernia, after reducing the hernia, he straps two-thirds of the abdominal wall with adhesive plaster, first taking up a fold the entire thickness of the wall, with the umbilicus and hernia in the depths of the fold. The adhesive plaster holds the fold firm, allowing the ring a chance to heal. The plaster is renewed by the physician himself every week or two; the child can be bathed as usual in the interim. This method obviates any danger of stretching the ring, which is liable when a small pad is used. He adds that these mechanical measures have to be long kept up; a year is none too long, provided the ring and the hernia show no tendency to grow larger. With careless or negligent parents and when the hernia is exceptionally large, operative measures are preferable and he reviews the various technics available. He applied Mayo's method in eight cases, including one in which the girl of 7 had a return of the hernia six months after it had been treated by merely resecting the ring and freshening the edges of the muscle. He never uses general anesthesia for it in young children; the operation is completed in about six minutes. He gave the older children a few whiffs of ethyl chlorid to supplement the local anesthetic.

Syphilis of the Nervous System.—Campo remarks that he often encounters persons who are victims of tabes or other syphilitic affections of the central nervous system who yet had taken supposedly thorough treatment according to the older methods. The action of the syphilis virus is sometimes reenforced by certain predisposing factors such as an inherited taint, fatigue of the brain and spinal cord, preexisting intoxications, traumatism and cold. These predisposing causes explain why nervous syphilis is more apt to develop between 20 and 40, is more frequent in men than in women, and is more prevalent in the city than in the country. The evidence on hand seems to indicate that the nervous system becomes infected during the secondary period. A mild meningitis may exist for years without making itself manifest, but it may induce infiltration in the meninges close to the posterior roots, and this may entail the clinical picture of tabes from the degeneration which follows the compression of the roots. He reviews the clinical picture of cerebral syphilis, and outlines our knowledge on the subject.

Semana Médica, Buenos Aires

*Serotherapy of Tuberculosis. J. Howard.—p. 305.
General Review of Congestions of the Uterus. Castaño.—p. 313.
*Technic for Resection of Megacolon. A. G. Gallo.—p. 318.
*Postoperative Dilatation of Stomach. O. Copello.—p. 323.
The Bases of a Scientific Education. J. Méndez.—p. 325.

Serotherapy of Tuberculosis.—Howard explains that the bacterium acts on the cells gradually, and in time trains them to produce antibodies. We have thus a durable immunization. Toxins, on the other hand, make a sudden, violent attack on the cells, and a chemical neutralization may follow, but the cells do not get trained, and consequently the immunization is comparatively transient. Vaccination against smallpox lasts for years, while vaccination with an antitoxin protects for only a few months. Immunity, he reiterates, is a process of cellular pedagogy. To realize it, he prepares an antiserum by successive passages of antigens and antibodies through animals, keeping always below the level of supersaturation. A number of cases of tuberculosis are described given a course of this antiserum treatment with very promising results. Full details of the preparation of the antiserum are to be given in a later article. He published in 1916 similar experiences with an antiserum for typhoid but explains that the brief course of typhoid does not allow time for the education of the cells.

Operative Treatment of Megacolon.—Gallo's remarks apply to removal of the sigmoid-rectal portion of the large intestine. He advocates both an abdominal and a perineal incision, and reviews the preferable technic with either long or short colon and mesentery.

Acute Dilatation of the Stomach.—Copello describes the case of a man of 50 requiring an interval appendicectomy that did not take over twenty minutes. The next day severe symptoms of acute dilatation of the stomach developed. The forty-fourth hour after the operation the stomach was rinsed out and the patient was turned to lie on his stomach. The vomiting stopped, but the symptoms returned again later, and yielded anew to the same measures. The pulse kept good throughout and there was no tachycardia. The vomiting was uncontrollable and the vomit was bloodstained at first. Peritonitis was excluded by the absence of pain and tenderness in the abdomen, although the fever suggested peritonitis, especially on the third and fourth days, but it subsided each time after lavage of the stomach. On account of the appendicectomy incision, he refrained from postural treatment except when absolutely required.

Introduction to Study of Operative Surgery. J. G. Capdevila.—p. 294. Cont'n.

Hemorrhages.—Morales describes a number of cases of alarming hemorrhage and the various means he improvised to meet unusual conditions. In one case the vessel broke on which an obese woman had seated herself, and the jagged edges of the fragments cut one of the external pudic arteries. Nothing arrested the hemorrhage until with a large curved needle, threaded with silk, the ends of the artery in the wound were brought together by this *acufilopresion* as he calls it. In one hemophiliac the hemorrhage after extraction of a molar resisted all measures until the cavity was seared with the actual cautery. Even this failed on another occasion, but the hemorrhage was finally arrested by *acufilopresion*, passing the silk over two segments of rubber tubing after lining the cavity with a fold of mucosa from the inside of the cheek. The loop of silk embraced all the mucosa surrounding the alveole. He has found hamamelis a valuable adjuvant in treating rebellious hemorrhage. It seems to act both by inducing coagulation and by contracting the muscular fibers of the blood vessels. In experiments on a dog, the femoral artery on each side was severed, and the hemorrhage arrested at once by application of a bag of ice on one side and by the hamamelis extract on the other. Then he applied a hot compress to the abdomen; this started up the hemorrhage anew on the ice-bag side, but not on the hamamelis side.

*Treatment of Placenta Praevia. G. C. Nijhoff.—p. 768.
Embolism of Pulmonary Artery. A. J. Krijger.—p. 776.

Racemose Phlebosarcoma.—Van Ree's patient was an otherwise healthy woman of 42; the sarcoma in the leg resembled in every respect a group of thrombosed varicose veins. The woman had noticed for some years a small bunch on the inside of her left leg, but for a long time there was no pain. The conglomerate of what looked like thrombosed veins was finally resected, but the contents proved to be sarcomatous, and the leg was amputated. There has been no sign of recurrence during the fifteen months to date. Illustrations are given of this peculiar racemose spindle-cell sarcoma, evidently starting in the intima of the vein, and the case is compared with the few other cases on record of cancer starting in a blood vessel.

Placenta Praevia.—Nijhoff analyzes the experiences in 160 cases of placenta praevia at Groningen since 1898. The mortality of the women was 8.2 per cent. and in four of the thirteen fatal cases the woman was nearly exsanguinated when first seen. The death rate of the children was 44 per cent. These figures compare favorably with Doederlein's compilation of 5,615 cases with 8.05 per cent. mortality for the mothers and 54 per cent. for the children. The lessons learned from this material impress the advantages of cesarean section in serious cases with profuse hemorrhage at the beginning of the first stage of labor. Otherwise it is better to follow the old method of rupturing the membranes, with version, when the os is well dilated. We may well be content if we can get the mortality of the mothers reduced to 5 or 6 per cent. and that of the children to 25 per cent. The details of his cases are tabulated.

Certain Requirements for Practice. I. C. Idenburg.—p. 846.

Sinus Arrhythmia.—Aalsmeer reviews the literature on this subject and describes in minute detail a case in which slight tachycardia was accompanied with sinus arrhythmia evidently traceable to some infectious process. Under digitalis the sinus arrhythmia grew worse and the conduction of the impulse became defective until the drug was dropped. Both the accelerator and the vagus systems seemed to be functioning perfectly, and the cause of the disturbances was evidently some change in the reacting organ itself. The prognosis in this tachycardia form is not so grave as in cases with bradycardia. With the latter, the heart action might become completely arrested.

Superficial Infectious Gangrenous Process.—The gangrenous process on the back of the hand of a man of 60 was traced to symbiosis of *Staphylococcus aureus* and *Bacterium lactis aerogenes.*

Inhibition of Agglutination Test by Fresh Serum.—Dikshoorn discusses van Loghem's assertion that the inhibition which sometimes occurs when fresh serum is used for the agglutination test is due to the presence of some nonspecific substance. By heating or by letting the serum age, this inhibiting effect is overcome. Dikshoorn's experiences with the blood of men vaccinated against typhus showed that the inhibiting action was most pronounced the greater the agglutinating potency. This suggests that probably the increase in the agglutinating property is due to an increase in the amboceptor content and that this, in connection with the complement, in a strong concentration prevents the binding of the agglutinins. With fresh serum there seems to be a mutual binding of amboceptor, complement and antigen which interferes with agglutination.

Total Pneumothorax Without Symptoms. H. Lindholm.—p. 723.
Health Record of Famous Romans. E. Ravn.—p. 735. Conc'n.

Contusion of Hernia.—Hindse-Nielsen reports four cases of rupture of the small intestine from contusion of a hernia. Only one of the patients survived the resulting peritonitis. The danger of such an eventuality should turn the scale in favor of operative treatment of simple hernia. The prognosis of rupture of the bowel in the hernia is somewhat better than rupture otherwise, if the herniated loop does not retract into the abdomen. He cites some statistics showing spontaneous recovery in 4 per cent. of 200 cases and recovery after operation in 28 per cent. of 469 operative cases. In any event, a trauma in the region of a hernia calls for extremely careful examination and exceptional caution.

*Stain for Diphtheria Bacilli. U. Quensel.—p. 384.
Influence of Massage on Pulse and Blood Pressure. R. Friberger.—p. 387.

Tuberculous Origin of Lymphogranulomatosis.—Näslund found nothing to suggest a tuberculous origin at necropsy of a typical and extreme case of lymphogranulomatosis in a boy of 4. None of the internal organs or tissues showed any changes even suspicious of tuberculosis. An emulsion of one of the lymphogranulomatous mesenteric glands was injected into the peritoneum of two guinea-pigs and both died of generalized tuberculosis. The tubercle bacilli found in the guinea-pigs were true to the human type, as also those recovered from white mice and rabbits also inoculated with glandular tissue from the lymphogranulomas. The lesions found in the animals corresponded to those induced with ordinary human tubercle bacilli, but some of the rabbits developed also certain changes which seemed to resemble in every respect typical lymphogranulomatosis, along with the ordinary typical tuberculous changes. The extensive researches reported, with four pages of bibliography, set solid, all tend to confirm the assumption that lymphogranulomatosis is a form of tuberculosis, the individual reacting forces determining the form in which the disease manifests itself. The tubercle bacilli involved are not necessarily attenuated in virulence.

Determination of Solid Contents in Urine.—Blohm's research seems to demonstrate that the refractometer technic gives more reliable findings than the specific gravity or other coefficients. In the sixty-three samples of urine tested, free from albumin and sugar, the range of solid contents was from 4.9 to 72 gm. per liter.

Effect of Massage on the Vessels.—Arnell has the arm placed in a cylinder of water before and after massage, the displacement of water indicating whether the arm has increased in size under the massage. Very little difference was apparent, and even this was not constant. The tests were made on fifteen persons from 18 to 27 years old, including eight healthy subjects.

Friberger's extensive experiments confirm that the slowing of the pulse and the hyperemia when an extremity is given a hot air bath far surpass what can be induced in this line by packing the extremity with hot sand bags; the effect with the latter of equally prolonged action (fifteen minutes) is very weak in comparison, and even this was realized only in 33 per cent. of the twelve persons tested. The diversity of the response in different persons to the tests was striking. Friberger reports also the effect on the systolic blood pressure and pulse rate of mud baths and soap massage baths. In six healthy young men no effect in this direction was apparent, but in fourteen persons from 20 to 63 years old, with chronic rheumatism, sciatica or polyneuritis, there was often a moderate rise in the blood pressure. There seemed to be some connection between the degree of pain induced by the massage in these cases and the amount of the increase in the blood pressure. He theorizes to explain this, and adds the practical warning that the possibility of thus raising the blood pressure should be borne in mind in cases in which there is reason to fear cerebral hemorrhage.

Simplified Stain for Diphtheria Bacilli.—Quensel says that with this stain all the slides with the smears can be left standing in the jar holding the stain until convenient to examine them. The stain keeps well, and the jar of stain can be used over and over again for months. It stains the nucleus as instructively as the Neisser contrast stain. He adds to a concentrated aqueous solution of methylene blue an equal amount of a 10 per cent. aqueous solution of cadmium chlorid. A precipitate is thrown down, and this precipitate is dissolved in water, when it is at once ready for use. The loopful of the culture is spread in a drop of the stain on a slide and air-dried, then placed in the jar of the stain for from two to five minutes or longer. It is then rinsed with water and treated for fifteen seconds with Lugol's solution, and rinsed again.

PROGRESS IN OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY *

THOMAS J. WATKINS, M.D.

CHICAGO

The honor you have conferred on me and the confidence you have expressed in electing me to this office are greatly appreciated. Your indulgence for any errors I may unwittingly commit and your assistance are earnestly solicited.

We are honored by the presence of distinguished surgeons from allied countries. We extend them a sincere welcome and a cordial invitation to participate in our discussions.

This is the Victory Meeting of the American Medical Association. It is an occasion for great rejoicing. Democracy has defeated autocracy. The chief victory celebration is scheduled for our general meeting; it is fitting, however, to make brief mention of the important part taken by members of this section. We point with pride to the vast numbers that rendered meritorious service. We rejoice that most of them have returned to their homes and civil duties. We hold sacred the memory of those who made the supreme sacrifice; we extend to their bereaved ones our sympathy, and pledge them our service.

The radical changes that have taken place in the titles and subject matter of contributions to the literature of gynecology, obstetrics and abdominal surgery during the last few years emphasize the fact that much knowledge has accrued and much chaff has been eliminated. Many of the subjects that were of much value and interest in the making have ceased to furnish opportunities for brilliant, and, at times, acrimonious discussion.

RECENT ADVANCE

A few examples of notable achievements will be touched on in order to illustrate the great advancement which has taken place in our specialties. Much has been accomplished in plastic surgery for the cure of cystocele, uterine prolapse, and rectocele. Operations for complete lacerations of the perineum and for vesicovaginal fistulas are relatively simple and efficient, when flaps are utilized and free separation of tissues, by blunt dissection, is made to obtain approximation without tension.

The importance of lacerations of the cervix has been determined to be chiefly its relation to erosions and leukorrhea. The investigations of Hitschmann and Adler, Sampson, and Curtis have demonstrated that curettage of the uterus is of little value except for diagnostic purposes, and is often attended by considerable danger, especially in septic cases.

The various operative procedures for retrodisplacement of the uterus have lost much of their interest; uncomplicated displacements have been found to be of little pathologic importance. A uterus so crippled that it cannot participate in reproduction should not be suspended; it is then useless and a menace to health.

The treatment of acute pelvic infections has made notable advances. It has become chiefly medical; surgery is largely reserved for relief from the residues of infection. This is especially true of acute puerperal infections. The chief danger to life in acute puerperal infections, excluding virulent streptococcus cases, has been found to be meddlesome, aimless, useless and dangerous traumatisms. Studies of nonoperative treatment of acute pelvic infections has long since revealed much knowledge of the important subject of acquired immunity. This achievement of the gynecologist has exerted an extensive and beneficent influence in the treatment of acute infections in all of the surgical specialties. These principles of treatment have of late been adapted to acute infections of the chest.

We can point with great pride to the accomplishments in abdominal surgery, especially to the fact that much important pathology was discovered by the abdominal surgeon—notably the pathology of the ovaries, fallopian tubes, appendix, gallbladder, and duodenal ulcer.

Study of the ductless glands has elucidated much hitherto obscure symptomatology of gynecologic cases, and has opened up a fertile field for further investigation.

Radium has proved to be a remedy of great value, as will be demonstrated by papers to be presented before this section.

OPPORTUNITIES FOR FURTHER PROGRESS

Notwithstanding all that has been accomplished, there remain many opportunities for research and improved surgery. Daily observations reveal the fact that much poor pelvic and abdominal surgery is done. Results are often disappointing. Subsequent surgery is often required.

Abdominal sections should have definite indications, and when performed, enough should be done to give assurance of a cure. Surgical tinkering with the ovaries, tubes and intestine is often a failure, and is frequently followed by disturbances necessitating further operation; such cases require very thorough study before surgical interference is resorted to. The character of the surgery in abdominal operations is too

---

* Chairman's address, read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

often exclusively determined by the pathologic condition found, instead of being adapted to the individual requirements. Similar pathologic conditions often produce very different symptoms in individual cases. The age, social status, and general health are also often important factors in determining the operative indications. It is highly important for the surgeon to have in mind an accurate history of the patient at the time of operation. I am convinced that the surgeon should keep the patient under observation after operation until the cure is complete. This is especially important for the neurasthenic type of patient.

No adequate opportunity is offered for the development of the younger surgeon. He is too often obliged to learn by independent practice. Assistantships and fellowships for selected men should be established in all of the larger hospitals. The time best suited for such study and development would be at the end of their internships. Many of these men are forced into general practice and commercialized medicine to gain a livelihood.

Division of labor by the surgical staff of most of the larger hospitals would result in much increased efficiency. An excellent example of this is found in the organization established by Halstead at Johns Hopkins, which has proved its efficiency by the development of men prominent in specialized surgery. His organization limits the field of work, permits intensive study, and supplies enough clinical material for extensive investigation.

Brain surgery well illustrates the advantage of such division of work. It should be done by one. The amount of material would be enough to develop one surgeon efficiently, but would be of very little value if distributed to all of the attending surgeons.

Examples of lack of organization are illustrated in the annual reports of most of our larger metropolitan hospitals. One large hospital, which has very little specialized surgery, publishes a volume of detailed technic of organization. Among the history forms is one of twelve pages for gynecology—a twelve-page, "rubber stamp" type of history for pelvic diseases in the female. It is not necessary to tell you that this hospital has no department of gynecology and abdominal surgery. None of us would employ such a history form for gynecologic cases. We might, however, have a form of twelve or more pages of history for nervous diseases, for diseases of the ear, or for any group of diseases which we are not competent to treat, but not otherwise.

Another hospital of about like size and character has a gynecologic department for the care of ambulatory patients, but no such special department for the care of hospital patients—an arrangement which does not suggest an organization established for efficiency. Both of these hospitals have medical college affiliations which have departments of gynecology. The inference would be that they consider specialists necessary for teaching but not essential for practice. These may be extreme cases but are illustrative of much of the lack of hospital organization. The men who are responsible for these conditions not only limit the usefulness of their institutions but restrict their own development.

The establishment of groups for surgical work is progressing and exerting a beneficial influence for better surgery. It is extending specialized surgery to the smaller communities. The combination of talent should bear the same relation to surgery that the combination of capital does to the industries. Such organizations in medicine should be for increased efficiency and not for increased profit. Organized groups established in large cities would result in much increased efficiency by development of more specialized surgeons. Organized groups would relieve the individual surgeon of annoying, time-consuming financial and other details, and would materially lessen commercialism. Groups could be of vast economic value by conservation of accrued accomplishments.

Much has been said relative to the practice of surgery by men with insufficient training. It is not my purpose or intent to offer any excuses for them, but to call attention to the fact that some of the responsibility for poor surgery rests elsewhere, especially with the men accountable to medical institutions of learning.

104 South Michigan Avenue.

CALCIUM CHLORID AS A PALLIATIVE AGENT IN THE TREATMENT OF INTESTINAL TUBERCULOSIS

MAURICE FISHBERG, M.D.
NEW YORK

With the exception of dysphagia and dysphonia due to laryngeal implication, the intestinal symptoms of tuberculosis are the most painful to endure and most difficult to control by our present methods of symptomatic and palliative treatment of the disease. In the advanced stages of phthisis, we very frequently encounter patients who beg for relief of the abdominal pains, exhausting diarrhea and tenesmus. These unfortunates, in despair of ever being completely cured of their malady, often state that if these intestinal symptoms were but controlled, they would be happy; but, unfortunately, until recently we have been practically helpless in many cases. The various astringents, metallic, mineral and vegetable, often prove of little or no value; the administration of silver nitrate, lead, bismuth and tannin and its derivatives, in moderate or large doses, has proved futile in the vast majority of cases; and dietetic treatment is only exceptionally effective in checking the frequency of the stools. Only large doses of opium or its derivatives are at times productive of a semblance of relief; but no sooner are the opiates stopped, often because of the appearance of untoward effects, than the diarrhea reappears, at times more severe and exhausting than before. Since between 30 and 50 per cent. of patients with advanced and active tuberculosis suffer from intestinal complications, it is clear that anything that will relieve these symptoms is a welcome addition to our armamentarium.

About six months ago, Saxtorph[1] published his results with the intravenous injection of calcium chlorid in intestinal tuberculosis. An abstract[2] of Saxtorph's paper was published in The Journal, and inquiries, asking for details of the treatment, were soon published,[3] showing the keen interest of those who have tuberculous patients under their care. Having given this method a trial in my hospital and private practice, I believe that my observations of the action of calcium chlorid in diarrhea of the tuberculous warrant its recommendation as a valuable therapeutic agent in the treatment of this symptom.

---

[1] Saxtorph: Ugesk. f. Læger **80**: 1763 (Nov. 7) 1918.

[2] Calcium Chlorid by the Vein in Intestinal Tuberculosis, abstr., J. A. M. A. **72**: 234 (Jan. 18) 1919.

[3] Calcium Chlorid in Intestinal Tuberculosis, Queries and Minor Notes, J. A. M. A. **72**: 443 (Feb. 8) 1919.

In some cases, Saxtorph's results were fully confirmed. The gastro-intestinal symptoms were almost completely relieved by a single injection of a 5 per cent. solution of calcium chlorid into a vein. The following cases are representative of this result:

REPORT OF CASES

Case 1.—R. G., aged 20, admitted to the hospital, Nov. 20, 1918, had a moderately advanced pulmonary tuberculosis involving both lungs, with fever, cough, night sweats, etc. Gastro-intestinal symptoms were a feature in this case, the patient complaining of severe abdominal pains and diarrhea, from six to eight movements of the bowels occurring daily, and fluid and ill-smelling material being expelled. The symptoms pointed to intestinal ulcerations, but there was no evidence of amyloidosis. The usual treatment with tannin, opium, etc., was not effective in giving the patient the desired relief. Feb. 15, 1919, 5 c.c. of a 5 per cent. solution of calcium chlorid were injected into the median basilic vein. Within several hours the abdominal pains disappeared, and the diarrhea was ameliorated. Only two movements of the bowels a day occurred after the treatment was applied, and the stools became semisolid. The improvement has lasted for more than three months, during which only dietetic measures have been enjoined.

Case 2.—A. B. K., a man, aged 37, admitted to the hospital, Nov. 19, 1918, had symptoms and signs of moderately advanced pulmonary tuberculosis, both lungs being affected. Soon after admission the patient complained of severe abdominal pains and constipation. The usual mode of treatment of these symptoms was not effective in giving him relief. In fact, the abdominal pains increased in intensity and diarrhea made its appearance, from six to eight loose movements occurring during twenty-four hours.

An intravenous injection of calcium chlorid was administered. Immediately after the injection, the patient felt a severe burning pain in the arm and over the precordium, and went into collapse. Stimulating medication revived him, but the pain in the arm continued for two days, when it finally subsided. The intestinal symptoms were, however, completely relieved. The abdominal pains and the diarrhea disappeared, the bowels moving only once or twice daily and the stools being well formed. No repetition of the treatment has been necessary for three months.

Case 3.—M. M., a man, aged 30, admitted to the hospital, March 5, 1919, though showing symptoms and signs of extensive tuberculous lesion in both lungs and a perforated ulcer of the nasal septum, had no severe constitutional symptoms of phthisis. His most urgent need was relief from the gastro-intestinal symptoms, abdominal pains and diarrhea, from four to six loose and watery stools being evacuated daily. There were no signs of amyloidosis. An injection of 5 c.c. of calcium chlorid intravenously was effective in improving his condition. The pains in the abdomen became milder, the movements of the bowels diminished to two a day, and the patient has been feeling quite comfortable for two months.

It appears that in some cases a single injection of the calcium chlorid is insufficient to effect relief of the gastro-intestinal symptoms and a second injection is indicated, as illustrated by these cases:

Case 4.—C. B., a man, aged 28, admitted to the hospital, March 9, 1919, had extensive bilateral tuberculous involvement of the lungs with signs of excavation; the larynx was also involved in the tuberculous process. The patient stated that since October, 1918, gastro-intestinal symptoms had tortured him—abdominal pains and diarrhea, with from four to six stools daily. March 15, 1919, 5 c.c. of calcium chlorid were administered intravenously. Relief of the abdominal pains was noted within a few hours, but the improvement in the diarrhea was not so pronounced. The number of stools was reduced to two daily, but they still remained loose. This improvement continued for about two weeks, when the old symptoms, abdominal pains and diarrhea, returned with the same severity as before the treatment was administered. Another injection of calcium chlorid was made and the diarrhea has been checked, not reappearing for two months. As long as the patient avoids dietetic indiscretions, his bowels move but once or twice daily, and the stools are solid or semisolid.

Case 5.—L. J., a man, aged 30, admitted to the hospital, Jan. 27, 1919, with far advanced pulmonary tuberculosis, stated that for two months prior to admission the gastro-intestinal symptoms had been so pronounced as to be considered by the patient of utmost importance. Constipation, continuing for several days, would alternate with diarrhea, which, checked by medicinal and dietetic treatment, would again be followed by constipation and abdominal pain. Feb. 23, 1919, during an attack of diarrhea that resisted medication, he was injected intravenously with 5 c.c. of a 5 per cent. solution of calcium chlorid. Relief was at once noted, and the gastro-intestinal symptoms were ameliorated within twenty-four hours. The pains disappeared, and the number of stools was reduced to two in twenty-four hours and they became of semisolid consistency. The relief proved short-lived. Three days later the old symptoms reappeared with the former intensity. March 9, a second injection of calcium chlorid was given, and this also was followed by relief in the gastro-intestinal symptoms for two days. March 13, a third injection was administered. The relief obtained was more enduring, the number of stools a day for a month diminishing to two or three. The abdominal pain, however, persisted.

In some cases the treatment failed utterly; repeated injections of calcium chlorid failed to give relief. The following cases are cited as examples:

Case 6.—J. G., a man, aged 21, admitted to the hospital, Nov. 2, 1918, showed symptoms and signs of advanced pulmonary tuberculosis with excavations. He stated that for about one year prior to admission he had been passing from eight to ten stools a day. All efforts on the part of his physician to check the diarrhea failed to afford relief. Feb. 26, 1919, an intravenous injection of calcium chlorid was administered. A slight amelioration in the pain and diarrhea was noted for two days, but then the symptoms returned with the former severity. A second and a third injection also failed to give relief.

Case 7.—A woman, aged 17, admitted to the hospital, Feb. 28, 1919, had advanced pulmonary tuberculosis. For about four months she had been suffering from severe gastro-intestinal symptoms, nausea, vomiting, abdominal pains and constipation alternating with diarrhea. During the first few days of her sojourn at the hospital from six to eight movements of the bowels occurred daily. March 5, 2.5 c.c. of a 5 per cent. solution of calcium chlorid were administered intravenously. No effect on the gastro-intestinal symptoms was noted. Another injection, this time of 4 c.c. of the solution, was given without influencing the diarrhea or the abdominal pains, and a third injection was similarly futile.

COMMENT

On carefully analyzing the cases in which this mode of treatment has been tried, it appears that the calcium chlorid is effective only in cases of early intestinal tuberculosis. When the diarrhea has continued only a few weeks it may be checked much better than with any medication or dietetic changes hitherto practiced. In such cases even the abdominal pains may be removed by calcium chlorid. In cases in which the diarrhea and pains have been present for several weeks, repeated injections of calcium chlorid may reduce slightly the frequency of the stools, but no amelioration is noted in the abdominal pain. It also appears that in cases in which there are symptoms and signs of amyloidosis, enlarged liver, polyuria, etc., the intestinal symptoms are not relieved by the treatment. It may be safe to make the following generalization: When the diarrhea in a tuberculous patient is due to dietetic indiscretions, to the catarrhal condition of the intestinal mucous membrane, or to slight intestinal ulceration, an intravenous injection of 5 c.c. of a 5 per cent. solution of calcium chlorid will give prompt relief. When, however, the intestinal symptoms are due to extensive ulcerations—especially to amyloid infiltration of the intestine—the chances of attaining relief of the pain and annoying diarrhea are remote. Similarly, when the abdominal pains are due to irritation of the intestinal mucous membrane by the contents of the intestine, relief may be attained by intravenous injection of calcium chlorid. When, however, the pains are due to localized peritonitis over deep intestinal ulcers, or to peritoneal adhesions, which are not uncommon in tuberculous subjects, calcium chlorid is impotent to give relief.

The mode of action of calcium chlorid in these cases can only be surmised at the present state of our knowledge of its physiologic action and pharmacology. We cannot explain it on the theory of lime starvation, which is said to be a strong etiologic factor in tuberculosis, because the administration of calcium chlorid has no influence on the other symptoms of phthisis. On the other hand, Loeb found that calcium salts stop contact irritability of muscle and the hypersensitiveness of the nervous system induced by various salts. It has also been found that calcium salts impede and even stop completely intestinal peristalsis; at times they even counteract the action of certain laxative drugs.

ANTIPNEUMOCOCCUS SERUM (KYES) IN THE TREATMENT OF LOBAR PNEUMONIA

JOHN H. McCLELLAN, M.D.
CHICAGO

The relative good fortune of Camp Grant in respect to epidemics from which many of the southern camps were severe sufferers during the winter of 1917-1918 made possible a more detailed clinical study of the cases of lobar pneumonia admitted to the base hospital during this period than could have been attempted under other conditions. The present paper was originally written with this idea in mind. When sent to France for final revision, the manuscript was lost and publication has been delayed. In view of the numerous reports from other camps dealing with the same subject, published during the past year, much of the original material of this article has become of little interest. The paper has therefore been abridged by the elimination of all discussion of bronchopneumonia and empyemas of streptococcic origin, and has been rewritten from the point of view of serum therapy. The figures have also been changed to include all cases in which the same method of treatment was employed, from May 1 to September 21, during which period Capt. Edwin F. Hirsch was in charge of the pneumonia wards.

The report includes only such cases as were beyond a reasonable doubt frank pneumococcus lobar pneumonia. There were 322 such cases which came under observation at the base hospital at Camp Grant, Rockford, Ill., from Oct. 1, 1917, to Sept. 21, 1918. No case was reported as lobar pneumonia nor is here included, which did not show definite lobar consolidation as evidenced by tubular breathing, increased tactile fremitus, bronchophony and flatness. This criterion of diagnosis was followed to eliminate those instances of respiratory infection of short duration and often due to pneumococcus, which simulate lobar pneumonia in that there is a sudden onset with high fever and severe prostration but in which, within twenty-four or forty-eight hours, recovery is rapid and in which at no time distinct consolidation occurs.

An early diagnosis, although frequently difficult, was made on the first or second day following the onset in approximately two thirds of the cases. Hyperresonance with distant breath sounds and slight voice changes occurred not infrequently on the first day. The changes in tactile fremitus and bronchophony were, on the whole, the most reliable and constant physical signs in the establishment of early lobar involvement.

BACTERIOLOGIC EXAMINATION OF THE SPUTUM

In all cases the bacteriologic examination of the sputum included the grouping of the pneumococci found therein according to the four so-called types. When the organisms could be identified as belonging to one of the first three types, the determination was of value in confirming the physical signs indicating pneumococcus lobar pneumonia. Unfortunately, however, two thirds of the organisms classified by means of mouse inoculation and the Avery method fell into Group IV, which in itself is a heterogeneous composite of such strains as do not fall into the first three groups and which offers no sharp distinction between certain pneumococci and certain streptococci. In a great majority of the cases, therefore, the sputum examination added no explicit early evidence as to whether the lung involvement was essentially a pneumococcus lobar pneumonia or a streptococcus bronchopneumonia, and was of corresponding slight clinical aid. The typing was continued systematically throughout the series, however, and Table 1 gives the occurrence of the organisms in terms of the four so-called types.

TABLE 1.—RELATIVE INCIDENCE OF TYPES OF PNEUMONIA

	Group				
	I	II	III	IV	Total
Number of Cases	43	56	13	190	311*
Percentage of cases	11.8	18.7	4.1	65.2	

* This total does not include eleven additional cases not typed.

LEUKOCYTE COUNTS

The daily leukocyte counts were made in all cases during the acute course of the disease, and were of some prognostic value. In general, the leukocytosis ranged between 15,000 and 30,000, but in twenty cases the initial counts were below 10,000. Of these cases, seven terminated fatally early in the attack, two others developed empyema and one a purulent pericarditis. The highest leukocytosis observed was in a case with a late crisis on the thirteenth day. In this case, the leukocytosis advanced from 30,000 to 67,000 during the ninth day. Modification of the leukocytosis by the immune serum treatment will be referred to later.

Approximately two thirds of the cases gave a history of sudden onset with a chill, and in five of these epistaxis occurred and in four vomiting. The history of a "cold" existing for from one to two weeks prior to hospital admission was given in approximately one third of all cases.

Almost without exception the cases at admission displayed a high fever, from 104 to 106 F., and an almost constant symptom was pleurisy, associated with severe respiratory distress. In twenty-one cases there was referred abdominal pain characteristic of diaphragmatic involvement, and in six cases the pain was referred also to the neck.

Herpes on the lips and face occurred in one third of the cases, and jaundice was distinct in fourteen cases, five of which terminated fatally. Cerebral symptoms were present in 12 per cent. of all cases, varying from the characteristic delirium to definite meningismus, the latter leading in three cases to a bacterial diagnosis by lumbar puncture.

USE OF THE KYES SERUM

In the treatment of all cases, systematic use was made of a polyvalent antipneumococcus serum prepared at the University of Chicago by Dr. Preston Kyes and described by him elsewhere.[1] In view of the results obtained by the previous use of this serum in 115 cases of pneumonia in a civil hospital, Major Joseph A. Capps, chief of the medical service, introduced the use of the serum as a routine procedure at Camp Grant, Oct. 1, 1917, and the results obtained were such as to indicate its continued use. It must be borne in mind, of course, that clinical evidence as to the efficiency of any therapeutic reagent is at best indefinite and must be accumulated in great amount and under varied conditions before final conclusions may be drawn. However, in this fairly large series of cases, the serum appeared to modify the course of the disease in several particulars with such constancy that it is the conclusion of those observing its use that the low death rate resulting should be interpreted as being in a considerable measure due to the therapeutic efficiency of the serum. In its action, the serum appears distinctly to reduce the toxemia, to reduce the general level of the temperature and especially that of the pulse. In most instances the leukocytosis is successively increased by injection of the serum; but this is not without exception. The impression is gained that in the large number of cases displaying a crisis on or before the fourth day, the sudden change bears a direct time relation to the injection of the serum.

The serum was employed for the most part intravenously, the usual dose being 2.5 c.c. once or twice daily. The total number of doses given varied from one to twelve with individual patients, in the average case from three to five injections being given.

A disadvantage attending the serum as first obtained was that on intravenous injection it provoked a marked temperature reaction accompanied by a chill of greater or less severity. The first twenty-five cases of this series were treated by serum which regularly produced this result, and the question naturally arose as to how great a part the foreign protein reaction might play in the apparent therapeutic effect of the serum.[2] To avoid this reaction, intramuscular injections of relatively large doses were resorted to for a time as a substitute for the intravenous injection. Later, however, the serum was furnished in a form which allowed its intravenous use without this disadvantage, and this avenue of introduction was then established as a routine.

Of the 322 cases under consideration, twenty-five terminated fatally, the death rate being 7.7 per cent. In two of the fatal cases, extensive preexisting chronic pulmonary tuberculosis was detected at necropsy, in one case general syphilitic arteriosclerosis and myocarditis were revealed, and in one case tonsillectomy had been performed two days before the onset of the pneumonia and three days prior to death.

Table 2 gives the death rate obtained in the cases grouped according to the type of pneumococcus as determined by the sputum.

TABLE 2.—MORTALITY RATE IN THE SO-CALLED GROUPS

	Group				Not Typed	Total Series
	I	II	III	IV		
Cases	43	56	13	199	11	322
Deaths	4	8	0	13	0	25
Mortality, per cent.	9.3	14.2	0	6.5	0	7.7

CONCLUSION

The low mortality in this extensive series of cases, together with the favorable modification of clinical symptoms by the serum, as stated above, would seem to indicate the extension of its use in pneumococcus lobar pneumonia.

122 South Michigan Avenue.

BACTERIAL CARRIERS IN THE UPPER RESPIRATORY TRACT

REPORT OF A SURVEY *

JAMES S. SIMMONS, M.D.
Major, M. C., U. S. Army
AND
ROY E. TAYLOR
Second Lieutenant, Sanitary Corps, U. S. Army
TAKOMA PARK, D. C.

The cases of pneumonia that occurred at the Walter Reed General Hospital between Oct. 1, 1918, and May 1, 1919, were classified bacteriologically from cultures of sputum, blood or organs at necropsy. The number of cases that developed each week are shown in the accompanying chart. Pneumococci were the organisms most frequently found in these pneumonias, and Types II and IV were much more prevalent than Types I and III. *Streptococcus hemolyticus* was relatively unimportant until January, 1919, when the cases showing this organism suddenly increased in number. It was feared that a large number of streptococcus infections might occur, as was the case last year following the measles epidemic, and at the suggestion of Col. F. F. Russell, M. C., U. S. Army, a survey of the post was made to determine the number of normal persons carrying hemolytic streptococci in their upper respiratory passages.

In the survey that was made between Jan. 26, 1919, and May 1, 1919, 3,174 persons were examined. This included the entire hospital personnel, all patients in the infectious disease wards and all patients admitted to the receiving ward. While we were primarily interested only in the prevalence of *Streptococcus hemolyticus,* it was decided to make pharyngeal cultures from the same persons for the pneumococcus and meningococcus. In the last 1,299 cases (March 13 to May 1, 1919) cultures were taken also for Klebs-Loeffler bacilli.

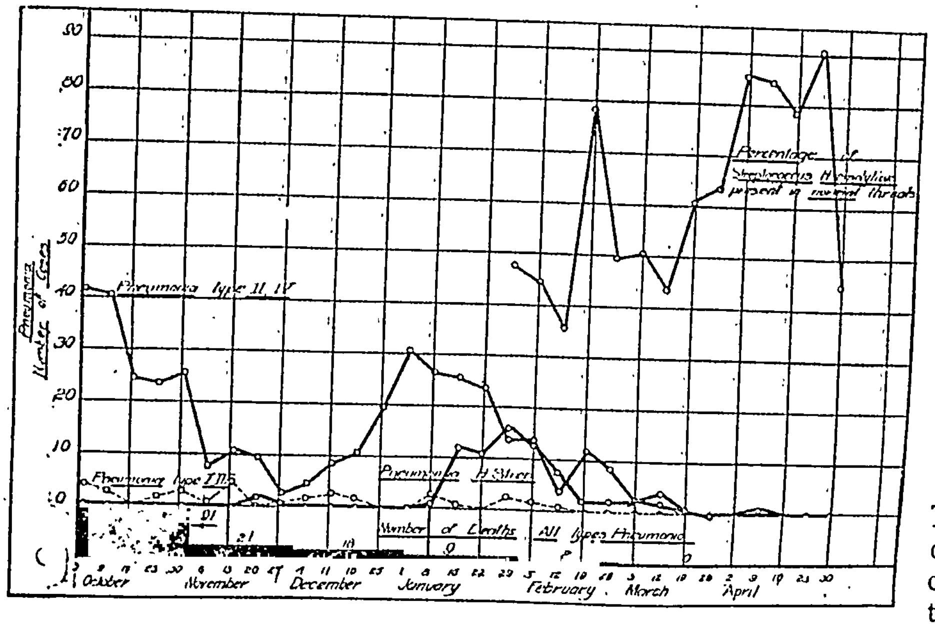
*From the Laboratory of the Walter Reed General Hospital.

TECHNIC FOR TAKING CULTURES

Cultures were taken in each case by means of a long bent wire swab which was first introduced into the nasopharynx to obtain material for the meningococcus plates (glucose serum agar). After these plates were inoculated, the same swab was used to obtain material from each tonsil and this material was transferred to blood agar plates to be cultivated for hemolytic streptococci and pneumococci. This swab was also used for making diphtheria cultures on coagulated serum mediums in some of the cases. By this method we were able to obtain a fairly representative culture of the upper respiratory tract.

The hemolytic streptococci were identified by the morphologic appearance of the colonies and the type of hemolysis produced on plain blood agar plates. Readings were made after twenty-four hours' incubation at 37.5 C., and the number of colonies were recorded as +, ++, +++ and ++++, depending on whether the streptococci represented one-fourth, one-half, three-fourths or the total number of colonies present. The same method was used in recording the number of pneumococci present. No attempt was made to determine the types of these organisms, and the accuracy of the pneumococcus results are therefore questionable. Only nasopharyngeal material was used in making plates for meningococci, as pure cultures are more readily obtained by this method. The latter cultures were incubated in a moist chamber devised and used last fall by Lieut. F. L. Gates, M. C., and Major J. H. Austin, M. C., at Camp Zachary Taylor.



Course of pneumonia at Walter Reed General Hospital.

After eighteen hours' incubation, typical colonies showing gram-negative diplococci were transplanted to be identified and typed by agglutination reactions later. Klebs-Loeffler bacilli were identified and typed by the morphologic appearance of the organisms after twenty-four hours' incubation on coagulated serum mediums.

RESULTS

Streptococcus Hemolyticus.—The total number of throat cultures made for hemolytic streptococci was 3,174, of which 1,774 (56 per cent.) were positive. Seven hundred and ten (22.4 per cent.) of the positive cultures were +, 462 (14.5 per cent.) were + +, 327 (10.3 per cent.) were + + + and 275 (8.7 per cent.) showed pure cultures and were called + + + +. The highest total percentage of carriers was found in the examination of patients admitted to the receiving ward, and the lowest in the hospital personnel on duty. The highest + and + + percentages were obtained from the receiving ward group, the lowest from the infectious disease group; the highest percentage of + + + + readings was from the infectious disease group, and the lowest from the hospital personnel.

TABLE 1.—STREPTOCOCCUS HEMOLYTICUS RESULTS

Group	Total	Total Positive		+		++		+++		++++	
		No.	%	No.	%	No.	%	No.	%	No.	%
Hospital personnel....	1,517	712	47	271	18	183	12	144	9.5	114	7.5
Patients, infectious disease group........	106	54	51	8	7.5	9	8.5	16	15	21	20
Patients, receiving ward group........	1,551	1,008	65	431	27.8	270	17.4	167	10.8	140	9
Total number of cultures...	3,174	1,774	56	710	22.4	462	14.5	327	10.3	275	8.7
Persons in whom cultures were taken after tonsillectomy	66	15	23	6	9	9	13.8	0	0	0	0

The weekly variations in percentages of positives is shown in the accompanying chart. The highest point on the carrier curve occurred, April 23, while only one case of streptococcus pneumonia occurred during the month of April. At this time cultures were made of sixty-six individuals on whom tonsillectomy had previously been performed. Six of these (9 per cent.) were +, nine (13.8 per cent.) were ++, and none were either +++ or ++++.

Pneumococcus.—Twenty-five per cent. of the 3,174 throat cultures were positive for pneumococci. The infectious disease group gave the highest percentage of positives (45 per cent.) while the receiving ward admissions were lowest (20.5 per cent.).

Meningococcus.—Ninety-four (2.99 per cent.) meningococcus carriers were found in the examination of the 3,174 nasopharyngeal cultures. Sixty-one (2 per cent.) of these were normal, thirty (0.94 per cent.) were para and four (0.13 per cent.) were intermediate types. Cultures were taken of forty-one of these positive carriers, none of whom had received any treatment, after eight weeks had elapsed. At this time only three "normals" and one "para" were still positive.

TABLE 2.—PNEUMOCOCCUS RESULTS

Group	Total	Total Positive		+		++		+++		++++	
		No.	%	No.	%	No.	%	No.	%	No.	%
Hospital personnel....	1,517	433	28.5	132	8.7	176	11.6	96	6.33	29	1.7
Patients, infectious disease group........	106	51	48	11	10.4	14	13.2	13	12	13	12
Patients, receiving ward group........	1,551	319	20.5	144	8.7	91	5.9	51	3.3	33	2.1
Total......	3,174	803	25	287	9	281	8.9	160	5	75	2.3

It is of interest to note that at this hospital, where no case of meningococcus meningitis has occurred since Oct. 28, 1918, the total percentage of nasopharyngeal carriers was only 2.99 per cent., while in a large number of nasopharyngeal cultures made from contacts of cases at Camp Zachary Taylor last winter, the positive reached 6.5 per cent.

Klebs-Loeffler Bacilli.—Eighteen (1.4 per cent.) positive cultures were obtained from 1,299 persons examined between March 13 and May 1, 1919. This is approximately the average percentage reported as normal by Goldberger, Williams and Hachtel.

SUMMARY

1. Over half (56 per cent.) of 3,174 persons examined at the Walter Reed General Hospital between Jan. 22 and May 1, 1919, were carriers of *Streptococcus hemolyticus.*
2. After tonsillectomy in sixty-six cases, only 23 per cent. of cultures showed hemolyticus streptococci, and in all of these the number of colonies was small.
3. A comparison of the weekly percentage of carriers with the weekly occurrence of infection failed to show that any direct relation existed between the two. Jan. 29, 1919, the streptococcus pneumonia curve reached its highest point, while the carrier percentage was at its lowest; and as the latter continued to rise, the former fell to the zero line.
4. For other organisms, the total positive percentages were: pneumococci, 25 per cent.; meningococci, 2.99 per cent., and Klebs-Loeffler bacilli, 1.4 per cent.

THE VALUE OF CHEST FLUOROSCOPY

RALPH C. MATSON, M.D. (PORTLAND, ORE.)
Major, M. C., U. S. Army
CAMP LEWIS, AMERICAN LAKE, WASH.

In their article on "The Value of Chest Fluoroscopy," Diemer and MacRae[1] state that their material is based on the roentgen-ray findings in 425 patients rejected on account of pulmonary tuberculosis by the tuberculosis examining board at Camp Lewis, American Lake, Washington.

Considering the fact that I was president of the board and that the tuberculosis examinations of the second-draft men sent to Camp Lewis were carried out under my supervision; furthermore, since a considerable amount of the fluoroscopic work was done by me and I do not find myself in entire agreement with the above-mentioned authors as to the value of chest fluoroscopy, I feel that in order to be fair to both physical diagnostic and to roentgen-ray procedures, the results of a comprehensive study of the examination of the second-draft material comprising 72,985 men should be presented. (The findings on 35,984 first-draft men examined by Major Ray W. Matson are also available, totaling in all 108,967 men examined. The entire report will be published later.)

Moreover, the authors present some figures that represent an analysis of the data from the standpoint of fluoroscopic findings in the rejected cases only, with entire disregard of the findings in the accepted cases, and they have not noted for comparison even physical findings in the rejected cases, consequently the figures presented are misleading and do not represent the rôle played by the roentgen ray, either in the examination of men rejected on account of tuberculosis, or in those who were accepted for military service at Camp Lewis.

NECESSITY OF COMPARING RESULTS

In dealing with a complicated subject matter such as "Value of Chest Fluoroscopy," trustworthy conclusions can be reached only after we have been compelled to look at the facts from opposite points of view, analyzing all the material at our disposition for study rather than a selected portion of it (rejects); and it is very doubtful also whether controversy is an effective means of determining the merits of opposing opinion regarding the value of a method or procedure, because most readers are left in a state of confusion as to where the truth lies and perplexity is certain to be the result of the discussion, unless full materials for controlling opinions are given. The logical weight of the different factors that influence opinions regarding the value of the fluoroscope in chest examinations with special reference to the tuberculosis examinations at Camp Lewis can be arrived at and given their proper value by the reader only when he has been made familiar with the organization and plan of examination followed by the tuberculosis board of Camp Lewis, and also when the fluoroscopic findings, not only of "rejects," but also of "accepts," are placed before him.

THE ORGANIZATION AND PLAN OF EXAMINATION

The organization and plan of examination employed at Camp Lewis has already been described by the writer.[2] The plan was the outcome of observations by Major Ray W. Matson in the examination of the command for tuberculosis at Vancouver Barracks, Washington, August, 1917. During the course of these examinations it became apparent that, in the absence of specially trained tuberculosis examiners, some plan would have to be worked out which would bring masked forms of tuberculosis and those with minimum physical findings to the attention of the president of the board. Accordingly an informal history form was devised and adopted for the work at Camp Lewis (Form 1, Camp Lewis Board).

The Camp Lewis tuberculosis examining board for the second draft was organized to examine 1,500 men daily and comprised twenty preliminary examiners (ten inexperienced) and two refer examiners (the president of the board and his assistant). The roentgen-ray work was done by Captain Diemer and Lieutenant MacRae with considerable assistance by the president of the tuberculosis board. Mention of my assistance is made because, in spite of many years of roentgenologic experience in the examination of the chest, I contributed to the hits and misses as shown by Table 1, and I have every desire to receive my share of the criticism directed against fluoroscopy and the part it alone played in the tuberculosis rejections at Camp Lewis.

SELECTION OF PRELIMINARY EXAMINERS

The preliminary examiners were selected from the infirmaries in the camp, few of them having had any recent training and none of them any special training in physical diagnosis. This should be borne in mind, because it has a very important bearing on the comparative value between the findings of the fluoroscopists and the clinical examiners as noted in Diemer and MacRae's article.

---

[1] Diemer, F. E., and MacRae, R. D.: The Value of Chest Fluoroscopy, J. A. M. A. **72**: 172 (Jan. 18) 1919.

[2] Matson, R. C.: Examination of Recruits for Tuberculosis, New York M. J. **108**: 199 (Aug. 3); 245 (Aug. 10) 1918.

In selecting preliminary examiners an effort was made to get officers who were especially interested in the subject, the idea being to give a considerable number of medical officers service on the board so that organizations going overseas would have at least one medical officer with some special knowledge of the diagnosis of tuberculosis. Therefore, fully half the personnel of the board was constantly changing on account of temporary assignments for duty during the incoming draft increments. The other half constituted a permanent board and was made up of officers who, during their temporary assignment, exhibited special talent. Each permanent member took a temporarily assigned officer under his supervision. The vast majority of the cases of pulmonary tuberculosis not recognized by the preliminary examiners but diagnosed by the refer examiners (many of these cases were diagnosed positively tuberculosis by the fluoroscopists before the case got to the refer examiners) were missed by the officers temporarily assigned.

TABLE 1.—FLUOROSCOPIST AND FLUOROSCOPIC DIAGNOSIS OF 570 REJECTED CASES DIAGNOSED PULMONARY TUBERCULOSIS BY THE REFER EXAMINERS ON THE TUBERCULOSIS BOARD

INSTRUCTIONS TO PRELIMINARY EXAMINERS

The preliminary examiners were instructed to interrogate each man verbally regarding family history, past and present history along the lines indicated in Circular B of this board, and according to the informal history form (Form 1 of this board). The physical examination was then made as suggested in Circular A of this board and Circular 20 S. G. O., following the principles so masterfully outlined by Col. George E. Bushnell, whose work cannot be praised too highly. If the preliminary examiner had reasons to suspect tuberculosis, either from the man's family history, past history, present history or the results of the physical examination, he was required to initiate the blank history Form 1, send the man in for fluoroscopic examination and to the refer examiner for opinion and disposition. In any event, this procedure was carried out in cases presenting any of the following circumstances:

A. History of prolonged contact with, or death in the family from, tuberculosis.

B. Inability to work because of ill health.

C. Well-defined history of previous pleurisy, pneumonia, frequent or protracted colds, typhoid fever or any other past illness of prolonged character, such as prolonged cough accompanied by expectoration, hemorrhage from the lungs or expectoration of bloody sputum, loss of weight or strength, night sweats, fatigue, etc. (A sputum examination was carried out in every case in which cough or expectoration was asserted, or râles of any description were heard on auscultation, except marginal râles.)

D. Existing cervical adenitis, tuberculosis of the bones or joints, or rectal fistula.

E. Asthenia and all cases in which the physical condition is manifestly below par; or lack evidence of stamina or resistance to disease.

F. Cases of chest deformity; scoliosis, kyphosis, funnel chest, pigeon breast, flat chest and barrel chest.

G. Cases in which physical examination reveals:
  1. Impaired resonance on percussion.
  2. Increased transmission of voice sounds over areas in which these are not normally increased.
  3. Abnormal breathing, such as sharpened vesicular or rough inspiration, with prolonged expiration, over areas in which this is physiologically abnormal —even though no râles are detected.
  4. All cases presenting râles, except marginal râles.
  5. Fixation of lung borders or Turban shading.

If the examination as just indicated was distinctly negative and the preliminary examiner was of the opinion that there was no evidence of disease of the lungs, pleura or mediastinum, he accepted the man and indicated this action by placing his number in an assigned space on Form 88 M.D. This enabled us to determine the examiner who was responsible in any case brought to our attention later.

On the other hand, if the man fell into any of the above groups (A, B, C, D, E, F, or G) the History Form 1 was initiated by the preliminary examiner and he filled in the important data bearing on the case. He also wrote in the result of the physical examination. In case of abnormal physical findings the preliminary examiner was obliged to record the results of inspection, percussion and auscultation. A diagnosis was required if a lung abnormality was noted. If tuberculosis was diagnosed the examiner was obliged to indicate the character, location, extent and activity of the lesion. In case of other lung disease, sufficient evidence was given to justify the diagnosis. The preliminary examiner then checked for sputum examination, provided the man stated that he suffered from cough and expectoration, or if any kind of râles, other than marginal, were detected on auscultation. He wrote his recommendation to the president of the board and his reason for referring the case to the roentgenologists and refer examiners; such as, "family history," "past history," "physical findings," "chest deformity," "asthenia," etc. The preliminary examiner signed the blank and placed his number on Form 88, together with an "H" to indicate that a history had been written. The papers were then returned to the conscript, who passed on to the clerk. They completed the history and sent the man in for fluoroscopic examination, which was carried out at once, the findings being typed on the history form, which was then sent to the refer examiner who reviewed all the evidence; namely, the completed history, physical examination by the preliminary examiner and his diagnosis, and the roentgen-ray findings. The refer examiner then either accepted the man on accumulated evidence without examination or the man was brought in for careful reexamination by the refer examiner.

WORK OF REFER EXAMINERS

If 1,500 men were examined by the board in a day it is probable that from three to four hundred fell into some one of the above groups. All records of these men were gone over by the refer examiners but all men were not reexamined, as reexamination of all refer cases was unnecessary. For instance, suppose in a given case the preliminary examiner found the lungs negative, but that there was a family history and contact history of tuberculosis, for which reason the man was referred; the refer examiner would accept the man without reexamination if the record showed the man working steadily, maintaining top weight, without cough or expectoration, in good general condition, good strength and roentgen ray negative or revealing only an abnormality. However, if the roentgenologic test diagnosed positive or suspicious tuberculosis or the man stated he was unable to work on account of sickness or loss in weight amounting to 10 per cent. in the two years previous to entering service, although this might be attributed to hard work, the man was reexamined. A reexamination was done in nearly every case irrespective of roentgen-ray findings, whenever the preliminary examiner noted a lung abnormality, whether diagnosed tuberculosis or not. In fact, reexamination by the refer examiner was carried out in all cases when there was any evidence suggesting tuberculosis either in the past or present history, physical findings by the preliminary examiner or by fluoroscopic examination.

INDICATIONS FOR REJECTIONS

Rejections were made by the refer examiners only and always after reexamining the man. Rejections were based on physical findings supported or unsupported by roentgenology. No man was rejected on roentgenologic findings alone.

This somewhat lengthy introduction was necessary, for one cannot hope to reach a decision in a controversy of this character and avoid lapsing into fallacy unless conversant with the above-mentioned facts.

DISTINCTION BETWEEN PRELIMINARY AND REFER EXAMINERS

From what has been said, it will be seen very clearly that the tabulation of results in Captain Diemer and Lieutenant MacRae's article is a comparison between the findings of the fluoroscopist and those of the *preliminary examiner,* as the rejections were based on the findings of the refer examiner who was the arbiter. The distinction between preliminary and refer examiners and their respective duties is not brought out in their article. The term "special examiners" used in the article should read, "refer examiners," and "clinical examiner" should read, "preliminary examiner." After recalling that the preliminary examiners, aside from the ten qualified, comprised officers for the most part inexperienced in chest examination, whereas the fluoroscopists had had extensive experience, it must be admitted that this comparison is not a rational one.

Of forty-one rejected cases that had been fluoroscoped by other fluoroscopists than Diemer, MacRae and the writer (Table 1) only 24 per cent. were diagnosed positive by them and over 9 per cent. pronounced negative, whereas the average positives were 55 per cent. and the average misses were 4.7 per cent. It will thus be seen that, although they were experienced fluoroscopists, their diagnoses were inaccurate, being vastly inferior to those of the inexperienced preliminary examiners, as will be noted later.

With these preliminary remarks in mind, Tables 2 and 3 become intelligible and reveal, I think, the facts of the situation. Table 2 shows an analysis of the examination of 72,983 second-draft men. We note that histories were recorded and roentgenologic examinations made in 16,589, or 22.7 per cent., for the reasons set forth, they thus falling into some one of the above-mentioned groups. Of this number, roentgenology reports 343 positive cases of tuberculosis (clinical verification unnecessary according to the authors), 1,500 suspicious, 2,349 with an abnormality (abnormalities in the illumination, such as haziness, general or localized, combined with lagging diaphragm, adhesions or obliteration of the pneumocardiac angle, marked calcification areas, etc.) and 12,393 negative. Of the 16,589 whose histories were recorded and who were examined roentgenologically the refer examiners accepted 12,096 on accumulated evidence (history, preliminary examiner's findings and roentgenologic findings). Most of those accepted without reexamination were in groups in which the lungs were found negative by the preliminary examiners and fluoroscopists. Only one of those so accepted without reexamination showed tuberculosis later. This case was one referred on account of a past history of pneumonia. The examiner pronounced the lungs negative, the roentgenologic examination was negative, and as the man had been working steadily with no loss of weight, being in good general condition and nothing otherwise suggesting tuberculosis, the refer examiner accepted him without reexamination. Three months later he was referred back by an infirmary surgeon. Examination revealed chronic active fibrocaseous tuberculosis. The sputum contained tubercle bacilli.

Of the 16,589 men whose histories were recorded 4,563 were reexamined and 570 were rejected on account of active tuberculosis, though according to the roentgenologic examination 1,843 were tuberculous and suspicious.

Diemer and MacRae state that they were unable to claim recognition of all the cases rejected (425—now 570) but that a considerable percentage was missed by the clinical examiners. Clinical examiners should read "preliminary examiners," as the diagnosis of tuberculosis was made by the refer examiner in every case and required no roentgenologic verification.

DISCUSSION OF REJECTED CASES

Let us examine the table of rejected cases (Table 3). Of the 570 rejects on the clinical diagnosis made by the refer examiner we note the roentgenologic examination detected 315, or 55 per cent. positive tuberculosis, while the preliminary examiners diagnosed tuberculosis in 299, or 52 per cent. (this represents the number under G, Table 3, sent to the roentgenologic laboratory, diagnosed active and inactive tuberculosis by the preliminary examiner and confirmed by the refer examiner)—a very slight difference indeed. Table 1 shows that the inexperienced fluoroscopist recognized as tuberculosis only 24 per cent. of the rejects. Let us compare Table 2 with Table 3. It will be seen in Table 2 that 343 were reported by the fluoroscopist as unqualifiedly tuberculous. The clinical verification, which it is stated was not necessary, was indeed necessary, not only to confirm the diagnosis of tuberculosis but to determine its activity, for only 315 were rejected

(Table 3) and twenty-eight were accepted for service with healed lesions. Of the 1,500 reported by the fluoroscopists as tuberculosis suspicious, Table 2, 1,372 were accepted by the refer examiners for full military service and are still intact, while 128 were rejected with unmistakable physical findings of chronic active fibrocaseous tuberculosis (Table 3). Of the 2,349 reported by the fluoroscopists with an abnormality (Table 2), 2,249 were accepted by the refer examiners for full military service and 100 were rejected by the refer examiners for chronic, active, fibrocaseous tuberculosis (Table 3); and of 12,393 reported negative by the fluoroscopists (Table 2) twenty-seven were found with physical findings sufficient to justify a diagnosis of chronic, active, fibrocaseous tuberculosis and they were rejected (Table 3). It is true that this is a small percentage of misses considering the number examined roentgenologically; nevertheless, 4,563 of the 16,589 so examined had to be carefully reexamined by the refer examiners in order to establish a diagnosis.

TABLE 2.—ANALYSIS OF CASES REFERRED TO REFER EXAMINERS—COMPRISING 72,983 SECOND-DRAFT MEN

Reason Preliminary Tuberculosis Examiner Referred Case to Refer Examiner	Number	Per Cent.	Roentgenologist's Report				Accepted by Refer Examiner on Accumulated Evidence Without Reexamination			Results of Examination by Refer Examiner and Disposition									Total Accepted	Per Cent. Rejected

We furthermore note (Table 3) 216 cases of active, pulmonary tuberculosis rejected, in which the refer examiners confirmed the diagnosis of the preliminary examiner, yet only 116 of them, or 54 per cent., were recognized as positive tuberculosis by means of the roentgenologic examination, just 2 per cent. better than the preliminary examiners did in all cases. These were all cases in which the preliminary examiners were able to make the diagnosis on physical findings alone. In the same column (Table 3), we note eighty-three cases sent to the roentgen-ray laboratory with diagnosis of inactive or healed tuberculosis by the preliminary examiner and confirmed by the refer examiner, of which only forty-seven, or 56 per cent., were positively diagnosed under the roentgen ray; and these were all chronic fibrocaseous types of tuberculosis, the very type of which Diemer and MacRae state: "The physical signs in the case of chronic and inactive fibrocaseous tuberculosis are minimal and susceptible of recognition only by the experienced clinician, but the screen findings offer unmistakable evidences of the abnormality in question.". The foregoing statement is certainly not in accordance with my experience, for the physical findings in this type of tuberculosis are invariably positive. As a matter of fact the roentgenologic examination revealed only an average of 54 per cent. positively tuberculous. Forty of the 216 active cases (18.8 per cent.) were pronounced suspicious and in forty, only an abnormality was noted, while in twenty (9.3 per cent.), the fluoroscopist reported lungs negative, failing completely to note fluoroscopic changes departing from the normal. In one of these cases three separate examinations by three fluoroscopists, including myself, were made, and all reported a negative result; yet the physical findings were beyond question.

NUMBER OF SECOND-DRAFT MEN DIAGNOSED TUBERCULOUS

It will be observed that, of the 16,589 second-draft men whose history was recorded and who were subjected to a roentgenologic examination (Table 2), 2,367 were diagnosed tuberculous by the preliminary examiners. In 1,843 cases the roentgenologist reported tuberculosis or "suspicious." The refer examiners, however, confirmed the diagnosis of tuberculosis in 884 cases only, of which 570 were chronic active lesions and therefore rejected, while 214 were diagnosed healed tuberculosis and accepted. All of these cases are intact. One of these cases selected at random is of interest and is typical of many accepted under like circumstances, all of whom have rendered efficient military service and are still intact.

E. B. R., aged 22, a private in the infantry, entered the service June 24, 1918. His occupation was that of farmer—working steadily. He was examined for tuberculosis at Camp Lewis, June 26. There was no tuberculosis in the family. Past history: He stated he had had typhoid fever in 1911, and had spat blood for three months before the onset of the fever (aspiration tuberculosis). Present history: He stated that he had had a cough for three days. He said he had "caught cold" on the train, but he stated he had raised sputum from the lungs all his life. His strength was good. He had no night sweats or other complaints. Examination: His height was 65½ inches; his weight was 131 (his highest weight); his general condition was good; the habitus was normal, and his attitude was active. The preliminary examiner reported the lungs negative. The man was sent to the roentgenologist and to the refer examiner on account of "past history." The roentgenologic report was: "Marked increase in density left apex. This is not marked but rather even uniform density. Right apex illuminates much better than left on coughing. Diagnosis: fibrocaseous tuberculosis." (An unjustifiable fluoroscopic diagnosis from findings noted). The sputum was negative. The refer examiner reexamined the man and found impairment of percussion resonance, bronchovesicular breathing, bronchophony, with narrowing of Krönig's isthmus over the upper part of upper lobe of left lung. There were no râles on expiratory cough. The diagnosis was: Healed tuberculosis. The man was accepted for full military service and was soon overseas. He returned from overseas to Camp Lewis for demobilization, Feb. 10, 1919. The soldier stated he had kept up his military duties and had had no sickness until he went into action in the Argonne, Sept. 24, 1918, at which time he was gassed. He was sent to a field hospital, in which pneumonia developed, Oct. 8, 1918. He was confined to hospitals until Jan. 6, 1919, and was then sent home with a convalescent detachment. His weight at the time of demobilization was 138 (7 pounds more than when he entered the service), but he weighed 150 pounds at the time he was gassed.

The preliminary examiner recorded that the general condition was good, the habitus normal, the attitude active, and the lungs negative. The man was sent to the roentgenologist and to the refer examiner because of the history of gassing. (All men stating that they have been gassed are sent to refer examiners.) The roentgen-ray examination was made by one of the refer examiners in this instance, who reported: "Fan-shaped area of increased density extending upward and outward from left hilum to apex. The left apex hazy and does not illuminate on coughing. Diagnosis: fibrocaseous tuberculosis."

Reexamination of the man by a refer examiner revealed identically the same findings as noted on his entrance examination and a diagnosis of healed tuberculosis was made.

The two records were compared and since the man was accepted with a healed lesion and it had remained apparently the same, the man's general condition being even better, he was discharged with a notation made on the certificate of physical examination prior to separation from military service (135-3 A. G. O.) that a healed tuberculosis was present but existed prior to induction into military service and had not been aggravated. The soldier claimed no disability and none was given. Had the refer examiner accepted the roentgenologic diagnosis the man would have been an original reject and the army would have been deprived of the services of an efficient soldier.

A consideration of the data from the standpoint of physical diagnosis was not given by Diemer and MacRae, and I think the fact that the roentgenologic examination cannot supersede physical examination is sufficiently brought out in the data already presented.

VALUE OF FLUOROSCOPY

However, one has only to study Tables 2 and 3 to be convinced that fluoroscopy in the case of certain groups was productive of good results. Its help in separating the wheat from the chaff in the groups in which the preliminary examiners found the lungs negative (A, B, C, D, E and F) was of particular value, bringing to the attention of the refer examiners for confirmation many cases of tuberculosis in men that in some other scheme would perhaps have been accepted by the preliminary examiners only to break down later. Attention is invited, for instance, to 1,015 cases in Group E, Table 2. The records of all show family history negative, past history negative, present history negative, "general condition bad," "asthenic habitus," etc. A footnote states: "Man has always been thin." The lungs are recorded negative, but the man is sent to the refer examiner because of "asthenia," "bad physical condition," etc. Of these 1,015, the refer examiners accepted 774, all with a negative roentgenologic test, on accumulated evidence without reexamination and all are intact. Of the 231 reexamined by the refer examiners, thirty-two were diagnosed chronic, active, fibrocaseous tuberculosis and were rejected, seventeen of the thirty-two being positively revealed as by the roentgenologic test. Of the 106 cases in this group designated as suspicious after the roentgenologic test and reexamined by the refer examiners, twelve were diagnosed chronic, active, fibrocaseous tuberculosis. Reexamination of the 118 reported with an abnormality on the basis of the roentgenologic test revealed three additional cases of fibrocaseous tuberculosis. These classes of cases undoubtedly represent a type that gets into the service and soon breaks down. A study of the other groups in which the preliminary examiners pronounced the lungs negative will reveal a similar splendid service rendered by roentgenology, a service which fully justified its use. Finally, it was of particular value in bringing to the attention of the refer examiners certain Class G cases diagnosed nontuberculous by the preliminary examiners. Tuberculous processes were often missed in these cases on account of coexisting acute and subacute respiratory infections, with loud sonorous and sibilant râles masking not only the character of breathing but keeping entirely in the background crepitant, subcrepitant and typical indeterminate râles. There were 2,859 cases of this character turned over to the roentgenologist and the refer examiners. By means of the roentgenologic test forty-two cases were diagnosed as positively tuberculous. The refer examiners confirmed this diagnosis in thirty-four and they were accordingly rejected. Eight were accepted with healed lesions and are still intact. In addition to these eight, there were thirteen other healed cases in this camp accepted. Of the 228 reported on the basis of the roentgenologic test as "tuberculosis suspicious," eighteen were rejected by the refer examiners. Of the 491 in whom only an abnormality was revealed by the roentgenologic test, twenty were rejected by the refer examiners, and, among the negatives, four were rejected, all on account of chronic, active, fibrocaseous tuberculosis, making in all seventy-six rejects, thirty-four of whom were found by the aid of the roentgenologist. Of the 2,859 belonging to this group, 2,051 were accepted by the refer examiners without reexamination and all are intact, 808 were reexamined. This included 761 found with abnormalities by the roentgenologist and forty-seven pronounced negative after the roentgenologic test but reexamined because the history and the preliminary examiner's findings, although the diagnosis was not positively tuberculosis, suggested its presence. Reexamination by refer examiners revealed four cases among the forty-seven.

PHYSICAL EXAMINATION AS COMPARED WITH ROENTGENOLOGIC FINDINGS

Careful physical examination generally predicts the roentgenologic findings. Roentgenologic findings alone are of little value unless interpreted by one having a knowledge not only of roentgenology but also of tuberculosis from a clinical and pathologic standpoint. The evidence furnished by roentgenology is only one link in the chain of evidence on which the diagnosis of tuberculosis is based. As compared with careful physical examination, the roentgenologic examination, even when done by an expert, occupies a place of secondary importance, so far as the diagnosis of tuberculosis in military service is concerned.

I have pleasure in expressing grateful appreciation to Captain Diemer and to Lieutenant MacRae for their conscientious and splendid work on the board. The closest cooperation has existed between the roentgenologists and the members of the tuberculosis board and this report is not to be interpreted as a reflection on the ability of Diemer and MacRae, for I consider both expert roentgenologists. They are not responsible for the things roentgenology has not done for us.

Furthermore, I do not wish to appear to be an opponent of roentgenology, for I have the utmost confidence in the procedure properly interpreted, but I must protest against the authors' statements regarding the rôle played by roentgenology in the tuberculosis rejections at Camp Lewis and against insinuations as to the unimportance of physical diagnostic methods in wholesale chest examinations.

This article is written, therefore, in a spirit of constructive criticism with a sincere desire to be fair to both the physical and the roentgenologic methods of examination. Both procedures have their place and must be held there. Neither can supplant the other; both are of value. I believe the authors claim more for roentgenology than it should be expected to yield.

GROUP STUDY, A NECESSITY IN OPHTHALMIC RESEARCH *

F. PARK LEWIS, M.D.
BUFFALO

In order that there may be a correct understanding of the nature of any eye disease, the clinical and the laboratory findings must be correlated. It is my purpose to urge that there can be no hope of our arriving at an exact knowledge of the occult causes of many of the most serious diseases of the eye by a study of the eye alone. In a vast proportion of the cases that come under the observation of the ophthalmologist, there is no possibility under present methods of associating his observations with complete physical examinations and laboratory findings. His best efforts are hampered and handicapped. It is imperative, therefore, as much in the interest of scientific progress as for the successful conduct of his work, that methods be devised whereby the ophthalmologist may be put in possession of all of the physical facts that have a bearing on the conditions which he is called on to treat. To accomplish this would be practically to revolutionize the practice of medicine. It would replace the individualistic by the combined method of clinical study.

The reason for the lack of unifying influence between the different specialties in medicine is not far to seek. The branches have grown independent of the plant. Individual departments have developed with surprising rapidity, but they have not been coordinated and synchronized. In practice, the work of the ophthalmologist is definitely and specifically limited. It is circumscribed by the orbit: with the conditions outside of the bony cavity in which the eyeball and its adnexa are contained, we are assumed to have nothing to do. But, of course, we know that that is not true. Our work not only is inseparably tied up with every branch of medicine and surgery, but also is related to all of the activities of the individual who comes under our ministrations. People do not come to us in large numbers simply because they cannot see as well as they think they should, but they come to us because they are sick and they expect us to help locate the source of their malady. They are justly impatient when, after having completed our examination of the eye, we consider our work as finished whether it has aided them or not in arriving at such an understanding of their condition as will again restore their bodily health. When ill, the practical man is not satisfied to be compelled to run the gauntlet of a circle of specialists unless he can be made to see the bearing which each of these has on his malady. The failure on the part of scientific medicine to locate the essential origin of many serious diseases is tending to lessen public confidence in medicine as a whole, and the time has come when we as physicians must reorganize our methods of practice, or means will be taken by the public, if not on the part of the state, to direct them for us, with results that may be equally disastrous for the public and for us.

The demand on the part of the public for adequate service for all of the people, not only the poor and the rich, but the mass of workers as well, has grown so insistent that some form of sickness insurance with all of its limitations is inevitable unless we are prepared with some concrete constructive plan which is better. A bromidic phrase that has been repeated so constantly that we have almost begun to believe it is that it is only the rich and the poor who secure efficient medical care. It is not true, even in regard to these two classes. The number of hospitals in the United States in which there is such collaboration between all the members of the staff and which is uniformly applied in all doubtful cases in the clinic is exceedingly small. In the larger number of public hospitals and dispensaries the same individualistic methods are used as there always have been, and the resultant consequence is a vast amount of labor on the part of medical workers with results that are unsatisfactory both to the patient and to the physician. We all know of innumerable instances of those able to pay the most generous medical fees; but, lacking the cooperation of those whom they have consulted, the real importance of the bearing of the findings of each is overlooked and the real diagnosis that might have been secured is missed. Of course, we all have endeavored to meet these difficulties by consultations, and in some instances have definitely arranged group practice; but the fact remains that for the mass of people whose resources are moderate, there exist no methods except through professional courtesy by which complete investigations can be made of cases that are obscure. If neither the very poor nor the very rich are able to obtain relief for their more or less obscure maladies, how much less fortunate in this regard is the great middle class, whose pride on the one hand forbids them to claim charity, and whose narrow purse on the other prevents them from purchasing the necessarily expensive services of high class physicians. The necessity of a rearrangement of the accepted methods is being universally recognized; but to no class of practitioners is its import greater than to the ophthalmologists.

We occupy a pivotal position. With the work that we do every other branch of medicine is correlated. It is impossible that our work should stand by itself. We may eliminate all of those diagnostic factors in which it has long been recognized that a knowledge of the conditions of the eye are important aids, for of course the ophthalmologist must be consulted in many cerebral and spinal conditions, and we are constantly called on to substantiate and interpret through a study of the eyegrounds the condition of the other organs; but there will still exist diseases of the eye affecting the sight the remote origin of which has not yet been determined. These must be determined, and it is as important for us as for our patients that our methods of research be enlarged. The break in the current by our isolation into narrowly defined specialties is the essential cause of the failure of medicine to occupy the dominant position to which it is entitled and which it must soon assume.

THREE IMPORTANT POINTS

In order that I may make clear the thought that I have in my mind, I should like to formulate the prob-

---

* Read before the Section on Ophthalmology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

lem which is not only of great importance to us but is also essential for the public good, and closely concerns our relation to the internist. I shall confine my reasoning to the special branch of medicine which we represent; but while the facts which I will ask you to consider relate with perhaps greater cogency to ophthalmologists than to those in other specialties, they will apply to every branch of medicine. Let me make this broad general statement, which is startling when its import is fully realized:

1. With few exceptions, the most serious inflammatory and degenerative intra-ocular diseases find their origin outside of the eye itself, and in the large majority of cases in tissues that do not come within the field of the ophthalmologist's explorations.

If this be admitted, and it can easily be demonstrated, it follows as a logical consequence that we, as individuals working alone and confining our studies to the eye, cannot ever hope to solve the ultimate causal problems that are daily presenting themselves to us.

The second point on which I should like to touch is the outgrowth of the first. It is this:

2. In order that we as ophthalmologists may reach the highest possible attainments within our own sphere of work, a readjustment of our present methods is imperative. Instead of working alone either as individuals or in ophthalmic hospitals and dispensaries, we must associate together in groups representative of every branch of medicine, so that to each case will be given that comprehensive and inclusive study that will enable us to diagnose with accuracy and to prescribe with definiteness.

But such a revolution in method cannot be easily undertaken. It would seem to connote the breaking down of the foundations on which the whole system of medicine has been built. I shall, therefore, suggest a third point for your consideration. It is this:

3. Changes of such far-reaching social and economic importance are already under way that the higher efficiency which cooperative medical measures would insure are being made a public demand, and it would be a source of pride for us to give form and direction to an advance movement that promises to be one of the greatest of the age.

Let me consider these three points briefly in order. Perhaps the most important work that has been done during the last few years is in biologic chemistry. The mechanism by which that perfect balance is maintained in the ultimate cell, in whatever part of the body, is profoundly disturbed by subtle toxins that find an entrance into the blood. The commonest source of these toxins is some focal infection retained under pressure. Sometimes pathogenic bacteria pass directly into the blood, producing bacteremia; sometimes a filtrable virus slowly percolated from a localized focus of infection, more especially when it is enclosed in bony tissue, is provocative of trouble. The locality which seems to be most commonly attacked is the alveolus. It may, of course, originate elsewhere, as in the tonsils, in one of the sinuses, in a partially filled root cavity of a tooth, or sometimes in a completely filled root cavity. Billings, in his "Lane Lectures" on focal infection, has shown what has many times since been proved, that "from pus and dead material of alveolar abscess and the infected pulp of the teeth, with a proper technic, cultures yield streptococci, chiefly *Streptococcus viridans* and *Streptococcus hemolyticus*, *Staphylococcus aureus* and *albus*, fusiform bacilli and other less important bacteria." Doubtless the endamebas play an important part in the occurrence of pyorrhea alveolaris and permit infection with pyogenic bacteria. The bacteria present in the infected areas are the important factors, however, in the causation of general infection from the focus. If, in a single case it can be shown that disease of the deeper eye tissues has resulted from the poison generated by a circumscribed alveolar abscess, then in no doubtful case of intra-ocular disease are we justified in neglecting to determine, by the aid of roentgenograms, the condition of the teeth. Unfortunately it is not safe for us to accept as conclusive a report of the findings of the most skilled dentists. It is their training and it has been their duty to conserve the teeth as long as possible. When we insist, then, on knowing what hidden conditions may be present we are very apt to meet the passive and even the active antagonism of the dental surgeon. In many cases, too, the external appearance of the tooth gives so little evidence of the condition of the deeper structures that the dentist appears to be fully justified in refusing to consider apparently sound teeth as a source of the danger. Moreover, the whole subject is so new that only the most progressive of the dental men have accepted the conclusion that the teeth may be an essential cause of remote pathogenic changes.

CONDITION OF THE TEETH IN EYE PATIENTS

Somewhat more than a year ago I determined that in every possible case in which there was evidence of disease of any kind within the eyes I would obtain, if possible, a skilled opinion in regard to the condition of the teeth. I was fortunate in having the cooperation in this of Professor McCall of the Dental Department of the University of Buffalo, who is not only a roentgenographer of unusual skill but a brilliant chemist and a trained observer as well. From him I learned that a rarefied area about the root of a tooth is always suspicious. It indicates that there has been some necrotic destruction of the bony tissues. It is often found associated with devitalized teeth. Consequently it is rare that there are any evidences of discomfort associated with it, but this area is largely supplied with rich lymphatic circulation, as shown by the researches of Sappey and later of Noyes and Dewey[1] of Chicago. We already have, then, perhaps all the conditions for the slow filtration of the bacterial toxins.

Independently of the reports of other dental surgeons, I have had with Professor McCall over 100 cases which have been carefully observed and which have received dental treatment.[2] Interesting as the individual study of these cases has been to me, the results when aggregated were even more so. I have them grouped in the accompanying table in order that they may more easily be seen. The patients whose cases are here synopsized came from various localities in New York State and Canada, so that it was not always possible to obtain a culture when teeth were extracted. Dentists, as a rule, are not provided with culture tubes, and it is not a simple matter to make a pure culture from a root cavity. From those that were obtained, however, the results are most interesting. I shall reserve the analyses of the cases for later study. It is interesting to note that in twenty-four of these cases, some form of pathogenic organism was found in the deeper structures of the alveolus. Thirteen of these cases were of retinal hemorrhage, which would bear out my contention that this condition is far more common than is generally supposed, and also, as I have endeavored to show,[3] that retinal hemorrhage is not dependent on the character of the blood pressure, which may be either high or low, but is due to some bacterial toxin usually given off from a focal infection which, attacking the endothelium in the small arteries or capillaries breaks down the tissue and the transudation of blood follows, not as a result of a too strong pressure from behind, but because of lysis in the vessel itself. This view, which I have not found elsewhere expressed, finds support in the observation of Billings, who has shown that the infection from a primary focus is usually hematogenous, the specific reaction consisting of a local inflammation with endothelial proliferation of the lining of the blood vessels and hemorrhage into the immediate tissue. In thirteen cases of cataract, either diseases of the teeth were found to exist or the teeth had all been removed at an early date, and there was evidence of intestinal toxemia. The association of infection with glaucoma and with detachment of the retina is particularly interesting. It leads to the interesting query whether the solution of the continuity in detachment between the retina and the underlying tissues may not be due, as in retinal hemorrhage and in the anterior softenings of the sclera, to the liquefaction of the normal colloids which in a condition of health are found between the retina and the underlying tissues. It is not my purpose to enter into a scientific discussion of the causes involved or the nature of that form of cataract wrongly called senile, but which evidently, as Roemer contends, depends on metabolic changes, but which, as he has not foreseen, is probably of toxic origin. It will be evident that this opens up an entirely new range of inquiry, the importance of which cannot be overestimated but which we cannot carry on alone. It leads me, then, to the second point about which I shall speak, which is the imperative necessity of cooperative methods in order that the results of our research may be purposeful and effective.

[1] Noyes, F. B., and Dewey, K. W.: The Lymphatics of the Dental Region, J. A. M. A. 71: 1181 (Oct. 12) 1918.

[2] Since I wrote the foregoing this number has been more than doubled.

SUMMARY OF SEVENTY-SIX CASES OF EYE LESIONS WITH DENTAL EXAMINATION FROM JULY, 1917, TO DECEMBER, 1918

Dental Conditions	No.
Apical rarefaction or other evidence of apical infection	59
Infected areas in bone following old extractions	8
Periodontoclasia occurring coincidentally with apical rarefaction	15
Periodontoclasia without apical rarefaction or other infection	2
Doubtful teeth, not extracted	10
No evidence of dental disease	5

CULTURES* CLASSIFIED BY LESIONS

Retinal hemorrhage	Staphylococcus albus	1
	Streptococcus hemolyticus	1
	Pneumococcus	1
	Diplococcus (encapsulated)	1
	Staphylococcus aureus	1
Cataract	Staphylococcus albus	2
	Streptococcus viridans	2
	B. pyocaneus	1
Glaucoma	Staphylococcus albus	1
	Streptococcus viridans	1
	Diplococcus (gram-positive)	1
Inflammatory	Staphylococcus albus	1
	Staphylococcus aureus	1
	Streptococcus viridans	1
Miscellaneous	Staphylococcus albus	1
	Staphylococcus aureus	3
	Streptococcus (various)	2
	Diplococcus gram-positive	2

Summary of cultures: Staphylococci, 11; Streptococci, 7; Miscellaneous, 6.

* All cultures listed were pure cultures. This does not exclude the possibility of loss of other organisms more difficult to cultivate.

NECESSITY OF COOPERATION

In endeavoring to make these inquiries I was much more fortunately situated than many of my colleagues. The courtesy of my friends, the biologists, always placed many laboratories at my disposal; but there are limitations beyond which courtesy cannot be pressed. Many of these patients also had blood counts and Wassermann tests. Some of them were gone over with great thoroughness by internists, but some of the most promising cases were those in which it was most difficult to make such cooperation available. They were people of moderate means who were unwilling to accept gratuitous treatment. No arrangement had been made by which it was possible adequately to compensate those who were contributing important results. They were not hospital patients on whom the staff's efforts might be concentrated. They were only a few of many who should have been given the same intensive study.

These cases made very clear the truth of my second proposition, that if we as ophthalmologists hope to solve such important questions as the cause and prevention of cataract, the reasons for glaucoma, and the nature of the chemistry which detaches the retina, we must have the laboratory invariably at our disposal, and we must have as collaborators all the other workers whose labors can have a bearing on these vital conditions. Recognizing its importance, how can this be secured? Fortunately, now when its necessity has become so apparent, the whole country has had an object lesson in the practical value of collaboration on the part of medical men on a large scale. In the first place, we have had the medical examining boards everywhere throughout the country. The facts which they have elicited in examining the men of draft age have been of such real value that it would not be a difficult matter to make the public realize how this work might be extended to include all of the people of the United States.

The ophthalmologist is the advance guard in the new movement. I have endeavored to show very briefly to what extent we, as ophthalmologists, are dependent not only on our own findings but also on a full and comprehensive understanding of the physical condition of the patient—if we expect intelligently to manage the most serious diseases which we are called on to treat; but having found out where the defects lie, we are still limited and hampered in a large number of the most important cases in having no place to which we can send them, with the assurance that their management will be in accordance with an understanding of the general as well as of the local conditions which are found. It is often impossible to secure a culture when the infected area is opened, and we are frequently unable to secure for our patient the treatment that would seem to be imperatively demanded; not because of difference of views but because of an inability to get that entire cooperation which can be obtained only when the light is thrown on an obscure condition from every angle. The same limitations and embarrassments occur in our medical relationships.

---

[3] Lewis, F. P.: A Bacterial Toxin as the Cause of Retinal Hemorrhage, J. A. M. A. **70**: 1813 (June 15) 1918.

I have in mind a pathetic case which came under my care recently through the courtesy of a friend in a nearby city. Himself a skilled ophthalmologist, he had discovered a double neuroretinitis in a young woman who had become so blind that she had to be guided about. Because of a stillborn child the family physician made a diagnosis of syphilis and persisted in the use of mixed treatment, although the sight continued to fail. She was urged to come to Buffalo in order that she might be taken, ethically, from a treatment that was obviously pernicious. When she was put under hospital care she was found to have albumin with hyaline casts and a negative Wassermann reaction. Both her eyes and her general condition responded to proper eliminative treatment, although she will always have exceedingly defective sight if progressive atrophy does not destroy it entirely. With a suitable group diagnosis such a thing would be impossible, because each examiner would be obliged in a general conference to justify his position, and his views could be accepted only after he had made the necessary findings and these were properly recorded.

If we, then, as ophthalmologists, are obliged to admit that our most careful examinations are limited and insufficient, the great problem that is forcing itself on us for solution is to determine some way by which complete methods of examination with well considered measures of treatment shall be secured for the masses of the people. The necessity is self-evident. That there are difficulties to be overcome is beyond question. But our men who in military encampments have learned the advantages of cooperative medicine will never be satisfied with anything less effective. Neither will the physicians who have had the opinions of the ablest men in the army be willing on returning to private practice to relinquish such benefits. A very ordinary young surgeon whom one would never think of accusing of idealism said to me that the satisfaction of practicing medicine under conditions in which a scientific and not a monetary consideration was the controlling motive had given him a degree of genuine pleasure of which he had not dreamed.

Why should not our medical examining boards which have been in active service all over the country be held together to continue to do for our civil populations what they have so well done for our soldier boys? The medical advisory boards could still be consulting bodies. The organization could be instantly called into existence again. It should be, as before, under federal control. Its functions should be limited to diagnosis, and it must of necessity work in the fullest harmony with the family physician. Who can estimate the amount of disease that could be prevented? Who can calculate the enormous saving which would result to the people? Our hospitals provide only for the cure of the sick. Each should have its facilities so enlarged as to become a diagnostic clinic developing the far higher phase of usefulness, that of preventive medicine. I am not hoping to present any completed and perfected plan. I am endeavoring only to make clear that the imperative corollary of modern medicine is cooperation on the part of medical men with each other and with the general public, and I am hoping that this section may be among the first to take measures looking toward the development of some plan which will at once add to the dignity and the efficiency of the profession to which we have devoted our lives, and in doing so to confer on mankind benefits of incalculable value.

ABSTRACT OF DISCUSSION

Dr. Walter R. Parker, Detroit: Dr. Lewis has presented a very interesting subject in diagnostic units. I am not so sure that it would not be better to devote our time to the organization of our present standards rather than to try to instill a little keener appreciation of the necessity of these general examinations on the part of the members of our branch of the profession. Dr. Lewis has very carefully chosen as his subject, "Group Study." In the organization of groups of men careful differentiation must be made between group study and group practice. Group study is idealistic. Some group centers for "practice" have been successful. Some have not. Organization alone will not answer the question. Repeated examinations alone will not answer the question. Organization and repeated examinations cannot take the place of a scientific education. Dr. Lewis suggested that the federal government have control of these units. It is possible that that will work out, but the results which have been attained through the management of the railroad companies and the telegraph and telephone companies, has not popularized such management. No matter how the organization takes place, there must be some authority which can enforce proper ethical standards and proper scientific treatment. We all know that we should have these general examinations, and in the everyday business life it is easy not to insist on getting them. I believe some change in that direction is going to take place soon, therefore let us look after the individual so that when the organization is formed the responsibility will be on the individual and not on the organization itself.

Dr. Alexander Duane, New York: Dr. Lewis suggests an ideal, which, as increasing experience shows, is not only desirable but also necessary. The more we study the subtle interrelations between the eye and other organs and realize the frequency with which we encounter them in our practice, the more we feel the necessity of the sort of group study that he advocates. That is true not only for scientific, but also for economic reasons. At present even in large cities, we are in an unfortunate position as regards our patients who are less well-to-do. Such a patient may come into the office with an eye affection which requires a whole series of examinations, and the ordinary purse nowadays is not equal to the demands made by a round of visits to high-priced specialists. Moreover, in the adjustment of appointments required in order to see every one of a set of men scattered over a large city valuable time may be lost. If a physician could command the services of a diagnostic institution, to which he could always refer any patient, whether with large or moderate means, the patient would receive the requisite series of examinations expeditiously and systematically, and would emerge with at least a complete and authoritative diagnosis. As a half-way step in this direction it has been suggested that in the larger cities each hospital specialize in some particular point of diagnosis, serologic and bacteriologic tests, oronasal and gastro-intestinal examinations, etc. But this plan fails to secure the very thing that, as Dr. Lewis points out, forms the essential feature in group study, namely, the correlation of different kinds of examinations by experts constantly in touch with each other and working hand in hand. Far better is the conception of a central institution—one in each of our large medical centers, ideally and completely equipped for diagnosis in all branches. Such an institution might with advantage leave treatment to be conducted at other hospitals, and devote itself solely to diagnosis and research. Such an ideal was promulgated over three hundred years ago by Francis Bacon, and such an ideal we might well try to realize today.

Dr. Albert E. Bulson, Jr., Fort Wayne, Ind.: In the not far distant past many ophthalmologists were inclined to look no further than the eye for the cause of some obscure eye diseases, but that criticism hardly holds true today as applied to the well trained ophthalmologist. We realize that we must not be ophthalmologists too exclusively, but that our explorations must go outside of the eyeball, and in arriving at an exact knowledge of some of the serious eye diseases we must take advantage of physical examinations and laboratory findings which are better carried out by others as proficient in their special lines as we are in ours. In discussing the group study of cases, Dr. Lewis has referred to the economic phase of the question, and here we are confronted with three classes of patients: first, those able to pay fully, those able to pay something, and those unable to pay little, if anything, essentially the charity cases. From the group study standpoint the first group should be cared for by calling to our assistance specialists in other branches and whose findings we need. The second group, likewise, may be handled in a similar manner, but with the understanding mutually agreed to by those in consultation that the work is partly gratuitous. The third, or charity group, belong in the clinics of our teaching institutions, or should be referred to hospitals where group study is made a part of the hospital social service work. There is a real necessity for cooperative medicine in all of our hospitals, whether connected with teaching institutions or not, and many of the ills which state medicine is supposed to correct for the poorer classes could be corrected by increasing the facilities of our hospitals so that diagnostic clinics, conducted by competent men, could be thrown open to the people who are unable to pay for private service. State medicine now being advocated for this country has not proved satisfactory or efficient from a medical, sociologic or economic standpoint in any country where it has been tried. It is class legislation of a socialistic and paternalistic nature which threatens disastrous results for the medical profession as well as for the public. No better way to stifle medical progress, do away with individual initiative of medical men and destroy self-respect and independence of the people, can be found than to put into force some form of paternalistic medicine. The poorer classes are in need of better medical and surgical attention as also hospital care, but this can be obtained by better cooperation on the part of both medical men and hospital organizations, both of whom always have been and always will be charitable, but the best results will not be secured by placing medicine under federal control.

DR. RICHARD J. TIVNEN, Chicago: Dr. Lewis has spoken of a problem which has long been a source of difficulty to most of us and his candor and analysis will undoubtedly be productive of much good. We are all, I am sure, in agreement with him, on the proposition that we, as ophthalmologists, cannot, working alone, make the scientific progress our patients have a right to expect of us and which we ourselves keenly desire. "Group study" along the lines suggested by Dr. Lewis would solve the difficulty. It is, however, as he has said, rather hard to inaugurate and continue such a plan of investigation. A campaign of education and propaganda among ourselves and among our confrèrs in other departments of medical work offers one promising method of solution. The ophthalmologist is not the sole culprit in the present unsatisfactory arrangement. The internist and the surgeon are equally culpable in not availing themselves more frequently of our services, investigations of our specialty. At most medical meetings—our own especially—this exclusion, this segregation, is accentuated by having the section work carried out in an exclusive way, entirely divorced from the work of other sections. We come to these meetings to attend this section only, rarely do we hear from workers other than our own Fellows; no opportunity is provided for us to get in touch with either the Fellows or the work of other sections, with the result that we go away as we came—eye men —to remain so to the end of the chapter. If a joint meeting, or several joint meetings, could be held with surgeons, internists, and all other specialists in attendance, and Dr. Lewis had read this paper before such a gathering, tremendous good would have been accomplished in furthering the "group" or "team work" study which Dr. Lewis advocates. I offer this as a suggestion to the officers of the section, that some means be provided at these meetings for a closer and more intimate association and interchange of scientific opinion with our fellow workers in other departments.

DR. OLIVER TYDINGS, Chicago: No injury can be offered to any organ of the body which will not have its effect on the eyes. With regard to the team work suggested by Dr. Lewis, there is not a conscientious man in the practice of ophthalmology who has not felt in need of just such work. Where is the remedy? Let the physicians and ophthalmologists refuse to aid any organization or institution whose sole object is to secure dollars. The government should be at the head of the national board, and every school should be under the control of national or state institutions.

DR. GEORGE S. DERBY, Boston: In Massachusetts an ophthalmologist can have special or general examinations made for $10 by sending the patient to a diagnostic clinic. There is an extra charge where the roentgen ray must be used. It has worked well up to the present time. The plan was discontinued owing to the war, but it will be put into operation again.

DR. GEORGE H. PRICE, Nashville, Tenn.: Diseases which find expression in the eye, due to constitutional involvement, can and should be treated as far as their diagnosis is concerned, by those most able, and best fitted to do that particular thing. In some communities it would be impossible to have at command the facilities at hand in the large centers. Ordinarily many cases come to the ophthalmologist concerning which he can reach a definite conclusion and apply those means which will reach the seat of the trouble, whereas, in others it would be almost impossible for him to reach a positive conclusion as to a definite single factor producing a disturbance.

DR. F. PARK LEWIS, Buffalo: As ophthalmologists we are occupying today an absolutely impossible position. We are endeavoring to do work without the agencies necessary to do it. We must devise some method by which the average man without hospital facilities at his command can get added knowledge to do that. The basic idea in my mind is community clinics.

THE AUTOTOXIC FACTOR IN SYMPATHETIC OPHTHALMIA [*]

ARNOLD KNAPP, M.D.
NEW YORK

An attempt to unravel the mysteries of sympathetic ophthalmia has been made by Elschnig, following an idea of Bail, by regarding it as an anaphylactic phenomenon. To explain the onset of inflammation in the healthy eye, he has assumed an additional factor in a general disease or autointoxication, and asserts that since following out measures directed to relieving this toxic state, no cases of sympathetic ophthalmia have been observed at his clinic. While the anaphylactic theory, though offering many suggestive lines of thought, has been criticized by some, especially on clinical grounds, and corroborated by others, as in the excellent research work of Alan Woods, the solution of this problem is still far in the future, on account of the many difficulties that belong to a most intricate chapter in serology and immunology. It is therefore needless for me to enter into a discussion of these questions on the basis of clinical observation, yet I venture to believe that the publication of the reports of four cases concerning the autotoxic factor in sympathetic ophthalmia may be of interest.

Attention has previously been drawn to general disturbance of health in sympathetic ophthalmia, and some have held that the constitution of the patient must be regarded. According to Schmidt-Rimpler's theory, in which Panas is of accord, sympathetic ophthalmia can attack only a person who is already ill. Elschnig assumes the presence of a somatic anomaly consisting in a constitutional disturbance, nephritis or injured eye is now white; there is a secondary cataract, with posterior synechia; light projection and tension are normal.

---

[*] Read before the Section on Ophthalmology at the Seventieth Annual Session of the American Medical Association, Atlantic City, N. J., June, 1919.

The autotoxic factor depended on the following: There was generally a history of improper diet and overeating, often associated with constipation. Examination of the stools was made by Dr. Dwyer in two of the cases and gave a highly toxic, acid stool, large excess of skatol and indol and exclusively gram-positive bacteria. Treatment, which was the usual one practiced in sympathetic ophthalmia, namely, mercurial inunctions, sodium salicylate, and pilocarpin sweats, did not seem to have very much effect. It should also be mentioned that the elimination of associated infections, abscessed teeth, and nasal sinus empyema did not exert any influence on the course of the disease. Regulation of the diet, thorough catharsis and colon irrigations seemed to be our most effective agents.

Objection has been raised against Elschnig's hypothesis of an autotoxic state in sympathetic ophthalmia; at least the demonstration of the symptoms and changes in autotoxemia have been vehemently attacked and dismissed as inadequate.

Treatment in sympathetic ophthalmia usually consists in mercury by inunctions, which is the remedy favored by the German writers, and large doses of sodium salicylate, by which Harold Gifford has obtained such brilliant results. It is true that in the cases of serous sympathetic iridocyclitis, the attenuated form, the patients usually get well, and it is hard to say how much any treatment helps. At any event, we do not know in what way either mercury or sodium salicylate acts in these cases.

I realize the temerity of advocating autotoxemia at the present day, and I am fully conscious of the many imperfections in the presentation of these four cases from an autotoxic standpoint; yet I feel the importance of investigating for a toxic factor in sympathetic ophthalmia, and if found present, its elimination in a prophylactic endeavor, as Elschnig suggests, cannot be passed by.

10 East Fifty-Fourth Street.

ABSTRACT OF DISCUSSION

Dr. Louis F. Love, Philadelphia: Dr. Knapp's theory of autointoxication has always appealed to me as being most attractive, but that there are other causes is illustrated, I think, by the case of Sister X, a religieuse, who was referred to me on account of rapidly failing vision in the right eye for three days. The patient stated that the eye had never been sore until three days ago, when vision was obstructed by a heavy cloud or haze so marked that she could not make her way about alone. On examination I found that vision in the right eye was 20/C with a correction 20/50. The eye showed slight pericorneal injection, the aqueous was cloudy and there were a few small deposits on the posterior cornea; no accurate view of the fundus was obtainable. The pupil was bound down by a plastic iritis, and could not be dilated under frequent instillations of cocain and atropin. About two years previously the left eye was removed because of a severe corneal ulceration due to a "gray ulcer." At that time a gold ball was implanted into Tenon's capsule. The socket appeared to be white and clean, and there was little or no injection of the conjunctiva or subconjunctival tissue. On making strong pressure on the gold ball toward the apex of the orbit, acute pain was elicited. The gold ball was removed. It was firmly adherent to Tenon's capsule and to the surrounding structures. I had to dig it out. It was in a perfect state of preservation, and there was apparently no disease of the capsule or surrounding structures. Energetic treatment was instituted, consisting of the instillation of cocain, atropin and ethylmorphin hydrochlorid (dionin), the application of stupes, the internal administration of quinin and sodium salicylate, sweats, mercurial inunctions and the application of leeches on the mastoid region and on the temple. Next day there was a most remarkable improvement in vision. The eye immediately became quiet and the aqueous was clear, but attempts at dilatation of the pupil were still unsuccessful. It was then discovered that several strong bands of iritic adhesions were present. In about a week the patient was practically well, vision with the old correction being 20/20. The pupillary space was clear, the nerve edges were plainly discernible, and beyond a few choroiditic spots of absorption no gross changes were apparent. The point of greatest importance brought out by thi case is the question whether the implantation of a gol sphere in Tenon's capsule is as safe a procedure as th implantation of a globe in the scleral cavity as performed i the Mules' operation.

Dr. George H. Bell, New York: I believe that it is possible for sympathetic ophthalmia to be produced by autointoxication from errors of diet. The case which interested me especially was the patient who had been a great eater of sweets. This patient had highly acid and toxic stools. These highly acid stools were reduced to a mild acidity when the patient was given a sugar free diet. That is one reason why I claim that sugar is a toxic substance. The sugar is acted on in the stomach by bacteria; fermentation takes place and several organic acids are produced which cause acid fermentation, hurrying the food out of the stomach and carrying the acid into the intestinal tract. As a consequence, poisons (toxins) are formed which are absorbed into the blood, causing autointoxication, and a train of toxic symptoms. In every case of sympathetic ophthalmia we should examine the feces and the blood, and we should make a diligent search for focal infections, before instituting any form of treatment. Last, but not least, we should have a constant supervision of the diet of these patients. The diet should contain sufficient base forming elements to neutralize the acids formed; in other words, to prevent acid poisoning.

Dr. S. Lewis Ziegler, Philadelphia: We should distinguish our relations of autotoxemia. There is no question that sympathetic diseases may be exaggerated, or made worse by autotoxemia, but as to its being a positive factor, there is some doubt. I think that the autotoxic condition is local, originating in the injured eye and being carried to the other eye. The toxic condition is manifested in the other eye through a certain chemical perverseness. We should consider the chemistry of the eye and the lymphatics of the eye. We know chemistry can do as much harm as germs. The second suggestion I wish to make is that turpentine is an excellent remedy in these cases. A patient who would not yield to any treatment recovered under the use of turpentine, ½ ounce in a 4-ounce mixture. The action is somewhat similar to the action manifested in the treatment of typhoid ulcer. Turpentine is useful in all congestions and in serous iritis it is almost a specific.

Fish in Relation to Mosquito Control in Ponds.—Under the direction of the U. S. Public Health Service, Samuel F. Hildebrand of the U. S. Bureau of Fisheries, conducted an investigation into what use, if any, could be made of fish for the purpose of controlling malaria by annihilating mosquitoes and their larvae. The result of his work was very encouraging. He found that *Gambusia affinis* is especially suitable for antimosquito work because (*a*) it seeks its food at the surface; (*b*) it is very prolific; (*c*) it gives birth to well developed young, therefore requiring no special environment for depositing and hatching the eggs; (*d*) it lives and thrives under a large variety of conditions and frequents areas especially suitable for the support of the mosquite larvae; (*e*) it usually lives and multiplies in ponds stocked with predacious fishes, providing it has very shallow water for refuge. The "star headed minnow," *Fundulus nottii*, was also found to be of value in antimalaria work. Its habits are very similar to those of *Gambusia*.—*Pub. Health Rep.* **34:**1113 (May 23), 1919.

PROCEEDINGS OF THE ATLANTIC CITY SESSION

MINUTES OF THE SEVENTIETH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT ATLANTIC CITY, JUNE 9-13, 1919

(*Continued from page 1844*)

THE SCIENTIFIC ASSEMBLY

THE GENERAL MEDICAL MEETING

Thursday Afternoon, June 12

A meeting on general medicine was held on the Garden Pier, June 12, at 2 p. m. Dr. Walter L. Bierring, chairman of the Section on Practice of Medicine, presided.

Address of Col. P. Nolf

PROTEOSE THERAPY BY THE INTRAVENOUS METHOD

Lieut.-Col. P. Nolf of the Belgian army, professor of physiology of the University of Liége, Belgium, said: Before the war, active measures against infectious disease had been divided into three groups: vaccines, serums and specific chemical substances. Lately a new therapy had been developed, called "proteose therapy," consisting of administration of protein by the intravenous method. Proteins, or "antigens," as they had been called, were characteristic toxins of animal or vegetable nature, foreign to the human body. The blood could be transformed into such a toxin by using merely the serum, or the corpuscles placed in distilled water. The introduction of this into the vein could produce the protein reaction, or protein shock. This shock was the effort of the organism to fix and assimilate the antigen introduced into the veins. If the introduction took place slowly, as in subcutaneous injection, the reaction was mild; if rapidly, as in intravenous introduction, the shock was more marked. In treatment for infectious disease, shock was avoided, but a mild reaction was advantageous. Small intravenous doses were preferable, but the technic was to be undertaken only by a physician conversant with its dangers, and careful watch was kept of the pulse, to note rapid fall of blood pressure. Slight palpitation, headache and rise of temperature followed, but passed off with profuse sweating, and improvement of the infectious symptoms was noted after one or two injections. Specific vaccines were more accurate, but both methods could be used in combination to effect a cure. The intravenous method was more rapid and gave better results in doses 1,000 times smaller than the subcutaneous route.

DISCUSSION

Dr. Henry Sewall, Denver, asked if there was any difference between the specific and the nonspecific antigen, and if the therapeutic results did not fall under the heading of desensitization rather than immunology.

Dr. Nolf said that specific therapy was more accurate, but one was in a hurry in cases of septicemia. One did not, therefore, wait to isolate the germ of the disease, for during that time the patient might get worse. One had to get in the dose of peptone quickly, and in the meantime the vaccine could be prepared, and it was often found that the patient had improved even before the specific vaccine was given.

Dr. S. H. Meltzer, New York, asked how the technic of intravenous injection was so slowly accomplished.

Dr. Nolf said that they utilized a syringe of 10 c. c., using a solution of 10 per cent. peptone, sterilized, and very clear. It was injected into the vein with a very fine needle, so that the flow took place drop by drop, during five minutes of time. If the patient was in bad condition, 250 c.c. of isotonic salt solution was put in and, the peptone [illegible] reaction was produced, as in the use of the concentrated solution. Occasionally 0.5 or 0.25 c.c. of 1:1,000 solution of epinephrin was used to avoid shock, in patients with very low blood pressure.

Dr. H. H. Hoppe, Cincinnati, asked if Dr. Nolf had had experience with meningitis.

Dr. Nolf said that this method was for general systemic and not for localized infections. It had been used in meningococcic septicemia.

Address of Dr. Senichi Uchino

NEW PLAN FOR IMPROVEMENT OF NATIONAL HEALTH IN JAPAN

Dr. Senichi Uchino, chief medical officer of the expert sanitary control board of the Home Department, Tokyo, Japan, said: As an urgent problem concerning the public health of Japan, a special board of investigation of national hygiene, besides the central sanitary board, was established in June, 1916, for the purpose of investigating and discussing all subjects relating to the preservation of national health.

The board for the investigation of national hygiene came under the control of the minister of state for home affairs, and the members of the board were appointed by the cabinet, not only from the high officials of all the departments concerned, but also including those persons who were experienced in such matters.

The matters which, it was decided, are proper for investigation include sucklings, infants and schoolchildren; tuberculosis; venereal diseases; leprosy; insanity; clothing, food and houses; hygiene of farm villages; and statistics.

The real condition of the nation's health must be carefully studied, and all the causes which are detrimental to it must be ascertained, and every means by which these causes can be counteracted eradicated, so that the health of the nation can be maintained and improved, must be investigated.

All these investigations must be made statistically, so that the present status of our national hygiene may be made manifest and the causes thereof accurately stated. All the theories of the West must be scientifically studied, as well as all the applications made thereof among the pioneering nations of the West. Often it may be found necessary to investigate personally the actual state of things in the West. To accomplish this object, those who are especially versed in public health study are to go abroad. This was what we expected to accomplish by establishing the present board.

The establishment of this board was really a new plan which organized during the last war. But the investigation is not yet concluded, and this hard work must be continued several years longer. Consequently, I cannot today report the results of our investigations. I believe, however, that the completed report of the results of this investigation will offer useful knowledge to those who have an interest in the public health of all the nations in the world.

DISCUSSION

Dr. W. Bierring said that this line of investigation was very much what was proposed in this country for the cooperation of various divisions associated under one central

Address of Major S. T. Lee

SOME DIFFERENT ASPECTS OF INFLUENZAL PNEUMONIA AND PEST PNEUMONIA

Major S. T. Lee, surgeon major, Chinese army, and Chinese delegate to the Interallied Sanitary Conference, Paris, said that last fall, when passing through this country to return to China, he heard much discussion as to whether the "flu" epidemic originated in China, the home of many curious and undesirable things. He would take this opportunity to present some differences between the pest pneumonia epidemic in China and influenzal pneumonia. In 1910-1911 there was an epidemic of pest pneumonia in China, with a death total of 50,000 and no recoveries. This occurred in Manchuria and northern Mongolia, disseminating itself along the Chinese eastern railways and lines of travel. In 1917-1918 another epidemic with a death total of 12,000, took place in southern Mongolia through the highways passing through the great wall. A third epidemic, localized in the central province of Sujan, took place this year, with eighty-three deaths. These epidemics had been proved to be due to plague and plague only. They took place in the winter months among the poorer classes. A plague bureau was instituted at Harbin, with branch hospitals, which, in normal times, were general hospitals, but were capable of being turned into emergency hospitals. This bureau had been able to keep the northern part of Manchuria free from plague.

The "flu" epidemic of 1918 broke out in separated villages, often separated from each other by uninfected areas. In some places the nervous types predominated, in others the gastro-intestinal types of the disease; there were few pneumonic types. Reports of plague, typhoid and of dysentery came from these places, but investigation showed that the disease was influenza.

This would give a general idea of the two epidemics prevalent in China. Dr. Lee said that in France he had served in a hospital last August in which all stages of the disease were seen, from mere cold and catarrh to pleurisy, pneumonia, empyema, abscess of the lung, and finally septicemia. At necropsy all the usual bacterial findings were made, but plague bacilli were never found. The epidemic could therefore be differentiated from the Chinese pest pneumonia. However, studies were being made in England and France to establish the identity of the filtrable virus, which was supposed to be the factor in influenza. This might be proved to be related to plague bacilli, but the bacteriology of the question was yet unsettled.

In regard to clinical differences, in influenzal pneumonia the lung symptoms persisted longer, there was more marked nervousness, and the pneumonia was a secondary complication superimposed on the primary disease. The features of plague pneumonia were different. In this disease forty-eight hours was the average course of the malady; in influenza from three to four days was the course, counting from the first appearance of the bloody sputum, which occurred in both types.

In regard to epidemiology, plague pneumonia occurred during the winter, whereas the grip pneumonia was at its height in autumn. Plague pneumonia occurred among the poorer class, and in influenza it occurred among all classes indiscriminately. In plague pneumonia, direct contact was necessary to contract the disease; but infection was often hard to trace in influenza. Nurses and physicians taking proper precautions did not contract plague pneumonia, but they frequently contracted influenzal pneumonia. In the laboratory examination of two persons who survived the plague pneumonia of 1918, plague bacilli were found in the sputum sixty-two and forty-two days after recovery from this disease. Carriers had been found in this, as in other infectious diseases.

DISCUSSION

Dr. Clinton Day, Hart, Mich., asked what was the general treatment in these cases.

Dr. Lee said that they had tried serums, but had given them up as hopeless.

Dr. Mener, New York, asked what precautions the physicians and nurses used.

Dr. Lee said that they avoided direct contact. They used the protection of masks and protective suits, gloves and aprons, which they removed on leaving the hospital. They also took an antiseptic bath. They wore goggles, as infection sometimes attacked the conjunctivae. In the second epidemic no deaths occurred among the medical personnel.

Captain Riggs, U. S. Navy, asked the dimensions of the third epidemic.

Dr. Lee said that it was confined to a single village and did not spread, as methods of handling it had been learned.

Address of Dr. John Constas

PREWAR AND POSTWAR IMPRESSIONS IN THE BALKANS

Dr. John Constas, delegate of the Greek army, said that Greece, and also the unfortunate nations of Serbia and Montenegro, had been at war since 1912, so that the peoples had suffered more in proportion, with the duration of the war. Commercial and medical supplies had been more interrupted. The treacherous and brutal Bulgars had proved the axiom that "birds of a feather flock together" by finally joining the Teutonic forces in spite of the persuasions of the Allies. At the beginning of the world war, the Greeks, under the régime of Constantine, the tool of the kaiser, were seriously handicapped, and were kept from joining the side of the nations fighting for humanity. However, it was psychologically impossible that a nation whose ancestors first gave the world a democracy should be kept back from their right to fight for freedom. The Greek nation passed through a very trying period, and during the days when the Mediterranean swarmed with submarines the true state of affairs of the Greek and Serbian armies and medical service were never known, though later when channels of news were cleared, the facts began to sift through. The frightful scourges of typhus and influenza, as they affected the Serbian people, were then appreciated. One fifth of the Serbians perished as a result of disease conditions. If not for the angels of mercy from America with nurses and ambulances, these terrible diseases would never have been checked. The whole sentiment of Serbia, Albania and Montenegro was one of heartfelt gratitude and more than gratitude for the American aid. None of these nations would ever forget what this country had done for them, so long as the earth should circle in its course.

THE GENERAL SURGICAL MEETING

Thursday Afternoon, June 12

A general surgical meeting was held on the Garden Pier, Thursday, June 12, at 2:30 p. m. Dr. John T. Bottomley, Boston, assisted by Dr. George P. Muller, Philadelphia, presided.

Address of Sir William Arbuthnot Lane

Sir William Arbuthnot Lane, London, England, said: I am delighted to be among you again. There may be some difference of opinion as to whether the American nation might have gotten into the war sooner, but there is no difference of opinion as to what the American medical profession did when war was declared. At the time I was over last I was much interested in a hospital for the improvement of those poor fellows whose jaws and faces had been partly torn away. We did some creditable work in that line. But now the war is over—we have almost forgotten it in England, which seems well—but the things we have learned during the war in regard to surgery we would like to carry on for the benefit of the races to come. It was my good fortune when I was here ten years ago to make the acquaintance of that great surgeon, Dr. Forrest Willard, who brought me to his institution. I have seen a good many wonderful things in the States, but the two most wonderful were the Willard Institute ten years ago and the Forsythe Hospital in Boston last year. They are taking care of the future. When this hospital of ours for mending jaws and faces shall have served its usefulness for the soldiers, I asked them if they would allow it to be used for the coming generation. I told them about the Forrest Willard and its wonderful work, and they said if we could establish such an institution as that they would give the land and the money. At the same time we will ask those people at the Forsythe institution to give their help and advice, so that we may have a dental institute in connection with the other. This we expect to accomplish.

Address of Dr. A. Depage

EMERGENCY OPERATIONS AND CONTINUITY OF TREATMENT

DR. A. DEPAGE, Belgium, said: I wish to develop two points which are of particular interest: The first of these concerns the emergency operating done during the war. When the Germans made the first drive in 1914, the wounded men were transported in most piteous condition to hospitals situated from 40 to 60 miles behind the line, and did not get there before from twenty-four to forty-eight hours. Then a hospital was opened 6 miles behind the lines, and we were able to get the patients from four to eight hours after they were wounded. This was great progress, but it was not enough, because we had such a heavy mortality. Then were created the advance post hospitals, only 2 miles behind the lines, and we got patients between two and four hours after they were wounded. These advance post hospitals were supplied with surgeons and nurses and material from a private hospital at Le Panne, and the mortality was reduced from 65 per cent. to 45.

The second point is the continuity of the treatment. This means that the patient should be treated by the same surgeon until completely recovered. Therefore this hospital has been enlarged in such a way that the treatment can be modified for the welfare of the men. The hospital is in several departments, with an experienced surgeon at the head, then six chief surgeons.

Address of Dr. R. Picqué

THE ADVANCED LINE SURGICAL STATIONS

DR. R. PICQUÉ, Medical Major of the French Army, and Professor in the Faculty of Medicine of Bordeaux, said: The formidable power of modern engines of destruction, and the number of men employed, has rendered necessary a parallel development of sanitary formations; the long duration of the war has permitted these formations to be realized. Hence the large evacuation hospitals (H. O. E.) of the army were organized to receive the large number of lightly and more severely wounded. But the seriousness and severity of wounds from artillery projectiles with resulting shock, hemorrhage and the rapid development of gas gangrene has rendered necessary the formation of surgical stations in the advanced line, operating in touch with divisions and Army corps. Up to the line, they stopped and here treated the most severely wounded, those unable to stand transportation, and thoracic, abdominal, dismembered and shock cases. However, even these stations were not sufficient, because of the terrible hemorrhage cases (femoral, axillary, carotid and pulmonary), in which the wounded arrived in dying condition to the advanced surgical stations.

Then, during that period of the war of strategic position,, were created on the western front even more advanced stations, to within 2 or 3 kilometers of the front lines, up to the opening of the evacuation trench. To save the dying hemorrhagic victim it behooved us to hasten the most advanced surgical posts or stations, branches of the group of advanced surgical stations of divisions in direct touch with the first aid stations of the battalion.

These most advanced surgical stations are subterranean, dug in, sometimes in the rear of a mountain (Vosges), on a ridge (as Argonne, Aisne), or at other times deep down under an open ground (Somme, Champagne, Flanders, Artois).

The object of the advanced surgical station is to restore the shocked, to operate if needed, to transfuse blood if necessary, and then to treat the patient on the spot for several days before his transfer in an ambulance. This is the antishock station.

Address of Prof. Paul Bégouin

TWENTY-EIGHT CASES OF CRANIOPLASTY

PROF. PAUL BÉGOUIN, Bordeaux, France, said: I performed cranioplastic operations on twenty-eight patients from August, 1915, to December, 1918, twenty-six times by cartilage transplantation according to the Morestin and Gosset method, and two times by bone transplantation according to the method of Delagenière.

My technic has been as follows: After shaving and disinfecting of the head with iodin, the patient is anesthetized with chloroform. By means of a semicircular incision going a little beyond the lower semicircumference involving the loss of bone substance, the hairy skin is incised as far as the bone; afterward the knife travels between the brain and the skin and a flap is thus created and raised. In the second step one frees every part involving bone loss from its adhesions both to the brain and to the dura mater. This is effected with the point of the knife, the brain being constantly protected by the end of the index finger. One ends by passing the end all around to make sure that the brain and the dura mater are entirely detached all along the circumference.

The second step of the operation consists in taking a cartilage transplantation. The region of the costal border has been asepticized at the same time as the head. It is now placed aside and surrounded by a clamp. With one stroke of the knife on the costal border and parallel to the latter, one makes an incision of 0.08 m. as far as the cartilage just outside the right muscle of the abdomen, the external border of which can be effected without any trouble. After placing inside the entire cartilaginous border, one takes Gosset's special chondrotome, or a simple knife, to cut the part intended for transplantation; in most cases the knife is enough, if one is careful in cutting the cartilage holding with the left hand index. The part intended for grafting is cut only as thick as half of the thickness of the cartilage border in order not to fracture the latter or weaken it too much. Then it receives the shape and dimensions just a little more than that amounting to the loss of the cranial substance. A sheet of sterilized paper has permitted the required design to be made while the first step of the operation is going on. If one piece of cartilage is not sufficient, one takes two or three. These grafts are placed on a piece of gauze and the wound is closed immediately. One takes care to make before a musculo-aponeurotic cover for it.

Then one goes back to the cranium, where the compression has usually stopped the flowing of either blood or fluid. The question is then to place the thinned borders of the cartilage graft between the brain and the internal side of the bone end so as to make them join together as the glass of a watch, the perichondrial surface being placed toward the brain. For the average case of loss of bone substance, one piece of cartilage is usually sufficient; when these are very large, I have had to utilize two and three pieces. With the grafts out of the way, it is sufficient to turn back the skin and stitch together.

The operation is borne well and does not cause shock. In a period of from five to eight days the cranial healing is complete, and that of the hypochondrium follows a few days later. When, about the eighteenth or twentieth day, the patients leave the hospital, their loss of substance is well replaced by a patch which may be a little elastic, but is solid just the same.

Operative Results.—Among twenty-eight cranioplastics performed, I have had neither death nor meningitis. I have had two failures; these were caused by the infection of the flap, the center of which was formed by a scar of a thinness too pronounced as a result of the first operation of craniotomy.

Curative Results.—Clinically speaking, the success was very satisfactory. It must be stated that in no case has the cranioplastic caused new troubles, and it has often suppressed them entirely and in every case brought about improvement in the existing condition. The epileptic crises have been a little modified, but the cephalalgia and dizziness have been often suppressed or at least influenced favorably. The sensitiveness to cold, heat, noise, and above all, that sensation so painful of dizziness which is present in the cases in which large loss of substance occurs, have disappeared entirely. Finally, all those operated on insist on the great satisfaction derived and the sensation of security they feel by knowing that thereafter their "brain is protected."

In the presence of these results, it seems that all those patients presenting a loss of cranial substance of dimensions approaching or exceeding those of a piece of five francs are proper subjects for a cranioplastic operation.

Address of Dr. Ernest W. Hey Groves

LESSONS FROM THE SURGERY OF WAR

Dr. Ernest W. Hey Groves, England, said: I want to speak to you a very few words, not so much about the organization of surgery in the war, but rather about the organization that ought to take place in surgery by reason of the war.

What a remarkable change has taken place since the dark days of 1914, 1915 and 1916. In the first place, it seems to me that foresight and preparedness and organization are the most important lessons—not to wait for the emergency to occur, but rather to prepare for it beforehand.

Then the next point, which has especially impressed itself on the surgeons and those interested in special branches of surgery, is the necessity for specialists.

No subject reduced us to such despair in the early days of the war as fractures. I may equally say that in the latter days of the war perhaps no subject has been more satisfactorily dealt with. That improvement was due, not to the genius of any one man or to the invention of any one apparatus, but simply to the principles of cooperation, continuity and team work.

In summing up I would mention three points: First, the surgical neglect of the well-to-do people. In our country, hospitals were originated by religious orders, and in the present day they are largely kept up as a matter of philanthropy, and these hospitals in our country for the most part are open only to the absolutely poor. I am not saying one word against that, but I fail to see why the possession of a reasonable amount of worldly property should debar well-to-do patients from the advantages of institutional treatment. In our country, if a man can afford to pay for surgical treatment and operation, he goes into a nursing home, or he has his operation done in his own home in a way which would not be tolerated for one single moment in one of the charitable hospitals. Organization, observation, research and that critical looking over of work by other people which is the safeguard of hospital work, is lacking in all the work done for the better class of patients.

My second point is that until the state takes up this question of surgical organization we shall never have an impartial, trustworthy record of surgical statistics. You are aware that many enthusiasts constantly come forward with suggestions for all kinds of claims that a particular operation is an absolute cure; and if one man has some new kink in an operation, a great number of men will go on performing this operation—it may be, even long after the originator has found out its fallacy.

My third point is an argument for state control of surgical organization. Throughout the war we have been tremendously helped by various philanthropic organizations, and I wish to record our great gratitude for the help of these organizations. But at the same time I do wish very seriously to protest against the important work of the treatment of the wounded being left in any way to what I may describe as "haphazard-philanthropy." The serious treatment of the wounded ought to be undertaken by the state from start to finish, and I urge that the encouragement of private philanthropy in that respect is not an advancement but rather keeps matters back.

MINUTES OF THE SECTIONS

SECTION ON PRACTICE OF MEDICINE

Wednesday, June 11—Morning

The section was called to order at 9:15 by the chairman, Dr. Walter L. Bierring, Des Moines, Iowa.

Dr. Bierring read the chairman's address, entitled "Relations of Internists to Military Medicine." No discussion.

Dr. George W. McCaskey, Fort Wayne, Ind., read a paper on "The Basal Metabolism and Alimentary Hyperglycemia Tests of Thyrotoxicosis." Discussed by Drs. John C. Hemmeter, Baltimore; Lewellys F. Barker, Baltimore; Nelson W. Janney, New York, and George W. McCaskey, Fort Wayne, Ind.

Dr. Henry S. Plummer, Rochester, Minn., read a paper on "The Classification of Goiters." Discussed by Drs. Emil Goetsch, Baltimore; Lewellys F. Barker, Baltimore; Henry A. Christian, Boston; George W. McCaskey, Fort Wayne, Ind.; Charles H. Mayo, Rochester, Minn., and Henry S. Plummer, Rochester, Minn.

Dr. James P. O'Hare, Boston, read a paper on "The Clinical, Functional and Pathologic Observations in Some Cases of Chronic Nephritis." Discussed by Drs. Herman Mosenthal, Baltimore; Edward F. Wells, Chicago; Lewis A. Conner, New York; Frank Billings, Chicago; L. D. Bulkley, New York, and James P. O'Hare, Boston.

Dr. Edward J. Wood, Wilmington, N. C., read a paper on "A Note on Tropical Sprue." Discussed by Drs. Douglas Vanderhoof, Richmond, Va.; Joseph H. Pratt, Boston; Walter C. Alvarez, San Francisco; Emanuel Libman, New York; M. L. Graves, Galveston, Texas; Alfred T. Livingston, Jamestown, N. Y., and Edward J. Wood, Wilmington, N. C.

The chairman appointed to serve on the executive committee, for this meeting, Drs. George Blumer, New Haven, Conn., and Charles F. Hoover, Cleveland, in the places of Drs. Roger S. Morris, Cincinnati, and Lawrence Litchfield, Pittsburgh, who were absent.

Dr. David Riesman, Philadelphia, read a paper on "Unusual Tolerance, Especially in Women, to High Arterial Pressure." Discussed by Drs. Joseph H. Pratt, Boston; Henry S. Plummer, Rochester, Minn.; L. F. Bishop, New York; James M. Anders, Philadelphia, and David Riesman, Philadelphia.

Thursday, June 12—Morning

Dr. Charles F. Hoover, Cleveland, read a paper on "The Clinical Study of Pulmonary Excursion." Discussed by Drs. Henry Sewall, Denver; Charles L. Minor, Asheville, N. C., and Charles L. Hoover, Cleveland.

Dr. Ralph Pemberton, Philadelphia, read a paper on "Chronic Arthritis in the Army: Observations Based on a Survey of Four Hundred Cases." Discussed by Drs. E. P. Joslin, Boston; Lewis A. Conner, New York, and Ralph Pemberton, Philadelphia.

Dr. Frank B. Wynn, Indianapolis, read a paper on "The Psychic Factor as an Element in Temperature Disturbance as Shown by Some Observations in the Selective Draft." Discussed by Drs. F. M. Pottenger, Monrovia, Calif.; Emanuel Libman, New York; Henry S. Plummer, Rochester, Minn.; F. B. Turck, New York; George D. Head, Minneapolis; E. F. Wells, Chicago, and Frank B. Wynn, Indianapolis.

Dr. Bertnard Smith, Los Angeles, read a paper on "The Importance of Physical Development in Cases of Effort Syndrome." Discussed by Drs. Eveleth W. Bridgeman, Baltimore; W. S. Thayer, Baltimore, and Bertnard Smith, Los Angeles.

Dr. Willard J. Stone, Toledo, Ohio, read a paper on "Pericarditis as a Complication of Pneumonia Based on Three Hundred Necropsies." Discussed by Drs. Charles S. Williamson, Chicago; Charles F. Hoover, Cleveland; William H. Robey, Jr., Boston; Henry Sewall, Denver, and Willard J. Stone, Toledo, Ohio.

Dr. Charles C. Bass, New Orleans, read a paper on "Effective and Practical Treatment of Malaria to Disinfect Infected Persons and to Prevent Relapse." Discussed by Drs. Charles S. Williamson, Chicago, and Charles C. Bass, New Orleans.

Dr. Thomas McRae and Elmer H. Funk, Philadelphia, presented a paper on "Errors in the Diagnosis of Chronic Pulmonary Tuberculosis." Discussed by Drs. Leo Kessel, New York; John A. Lichty, Pittsburgh; F. M. Pottenger, Monrovia, Calif.; A. G. Shortle, Albuquerque, N. M., and Elmer H. Funk, Philadelphia.

Friday, June 13—Morning

The following officers were elected: chairman, Dr. James S. McLester, Birmingham, Ala.; vice chairman, Dr. Joseph H. Pratt, Boston; secretary, Dr. G. Canby Robinson, St. Louis; delegate, Dr. Roger S. Morris, Cincinnati.

The chairman requested Dr. W. S. Thayer, Baltimore, to preside. After defining the divisions of professional work in war medicine, and commenting on the leadership of a number of American physicians in caring for the expeditionary forces, Dr. Thayer introduced the first speaker.

The following papers were read as a "Symposium on Medicine in the American Expeditionary Forces":

Dr. Maurice C. Pincoffs, Chicago: "The Division: Evacuation and Ambulance."

Dr. George Draper, New York: "The Corps and Army."

These two papers on "Problems at the Front" were discussed by Drs. Homer F. Swift, New York, and W. S. Thayer, Baltimore.

Dr. Joseph A. Capps, Chicago: "The Work of the Group Consultant."

Dr. Joseph Sailer, Philadelphia: "The Work of the Group Consultant."

These two papers on "Problems at the Base" were discussed by Drs. R. T. Woodyat, Chicago; Robert H. Halsey, New York, and William Darrach, New York.

Dr. Richard Dexter, Cleveland: "Immediate Recognition and Evacuation of Gas Cases."

Dr. Alfred E. Cohn, New York: "Later Effects."

Dr. Alwin M. Pappenheimer, Hartsdale, N. Y.: "Pathology."

These three papers on "Poisonous Gases" were discussed by Drs. Maurice C. Pincoffs, Chicago; W. S. Thayer, Baltimore; M. W. Ireland, Washington, D. C., and S. J. Crumbine, Topeka, Kan.

Dr. Homer F. Swift, New York: "Trench Fever."

Dr. Warfield T. Longcope, New York: "Influenza."

These two papers on "Specific Infections" were discussed by Drs. W. S. Thayer, Baltimore; Albert E. Roussel, Philadelphia; R. G. LeConte, Philadelphia; Ernest Zueblin, Cincinnati, and Homer F. Swift, New York.

Dr. Reginald Fitz, New York: "Nephritis in the Soldier." Discussed by Drs. Louis Feid, Jr., Cincinnati; E. P. Joslin, Boston; H. E. Jones, Roanoke, Va.; Homer F. Swift, New York, and Reginald Fitz, New York.

Dr. Marion A. Blankenhorn, Orville, Ohio: "The Treatment of Chest Injuries." Discussed by Drs. W. S. Thayer, Baltimore; Ernest Zueblin, Cincinnati, and Marion A. Blankenhorn, Orville, Ohio.

SECTION ON SURGERY, GENERAL AND ABDOMINAL

Wednesday, June 11—Afternoon

The meeting was called to order at 2:15 by the chairman, Dr. John T. Bottomley, Boston.

Dr. Bottomley read the chairman's address. No discussion.

The following foreign guests occupied seats on the platform: Dr. Antoine Depage, La Panne, Belgium; Dr. Joseph Vande Velde, La Panne, Belgium, and Major Robert Picqué, Bordeaux, France.

The chairman announced that an amendment had been adopted by the House of Delegates whereby the election of officers would occur on Friday afternoon.

Dr. Walter B. Cannon, Boston, read a paper on "Traumatic or Wound Shock."

Dr. Bertram M. Bernheim, Baltimore, read a paper on "Hemorrhage and Transfusion."

These two papers were discussed by Drs. George W. Crile, Cleveland; Oswald H. Robertson, New York; Howard T. Karsner, Cleveland; Major R. Picqué, Bordeaux, France; Richard Lewisohn, New York; Walter B. Cannon, Boston, and Bertram M. Bernheim, Baltimore.

Dr. Dean D. Lewis, Chicago, read a paper on "Debridement."

Dr. Eugene H. Poole, New York, read a paper on "Primary and Secondary Suture."

These two papers were discussed by Drs. Fred W. Bailey, St. Louis; Fenton B. Turck, New York; Donald McRae, Jr., Council Bluffs, Iowa; W. M. Thompson, Chicago; Kellogg Speed, Chicago, and Dean D. Lewis, Chicago.

Dr. Frederick T. Van Buren, Jr., New York, read a paper on "Gas Bacillus Infection."

Dr. George A. Stewart, Baltimore, read a paper on "Sterilization of the Wound."

These two papers were discussed by Dr. Antoine Depage, La Panne, Belgium (translated by Dr. Joseph Vande Velde, La Panne, Belgium), and Fred W. Bancroft, New York.

Thursday, June 12—Morning

The meeting was called to order at 9:15 by the chairman.

Dr. Charles H. Mayo, Rochester, Minn., read a paper on "War Problems." No discussion.

Dr. Charles H. Frazier, Philadelphia, and Samuel Silbert, New York, presented a paper on "Peripheral Nerve Injuries." Discussed by Drs. Martin B. Tinker, Ithaca, N. Y.; W. W. Babcock, Philadelphia; Charles Bagley, Jr., Baltimore; Alfred W. Adson, Rochester, Minn.; Joseph Byrne, New York; Arthur C. Stokes, Omaha, and Charles H. Frazier, Philadelphia.

Dr. W. W. Babcock, Philadelphia, read a paper on "A New Method for the Immediate Sterilization and Closure of Chronic Infected Wounds of Bones and Soft Tissues." Discussed by Drs. Floyd W. McRae, Atlanta, Ga.; Angelo L. Soresi, New York; Albert J. Ochsner, Chicago, and W. W. Babcock, Philadelphia.

Dr. Vilray P. Blair, St. Louis, read a paper on "Maxillofacial Injuries." Discussed by Drs. Robert H. Ivy, Philadelphia; George M. Dorrance, Philadelphia; John B. Roberts, Philadelphia, and Vilray P. Blair, St. Louis.

Friday, June 13—Afternoon

The chairman called the meeting to order at 2:12 o'clock, and announced that he had appointed Drs. Charles H. Peck, New York, and J. Bapst Blake, Boston, on the executive committee in place of Drs. E. Starr Judd, Rochester, Minn., and E. Wyllys Andrews, who were absent.

The following officers were elected: chairman, Dr. Dean D. Lewis, Chicago; vice chairman, Dr. Marvin Clopton, St. Louis; secretary, Dr. George P. Müller, Philadelphia; delegate, Dr. Raymond P. Sullivan, Brooklyn, alternate, E. Denegee Martin, New Orleans; representatives on the board of governors of the American College of Surgeons: Drs. James F. Mitchell, Washington, D. C.; William Darrach, New York, and William E. Lower, Cleveland.

The following papers were read as a symposium on "War Fractures":

Dr. Joseph A. Blake, New York: "War Fractures." Discussed, with lantern slides, by Drs. Morris K. Smith, New York, and Ralph T. Knight, Minneapolis.

Dr. Ernest W. Hey Groves, Bristol, England: "War Fractures."

Dr. John B. Walker, New York: "Statistical Summary of War Fractures."

Dr. Pedro Chutro, Buenos Aires: "Osteomyelitis After Injury."

Dr. Fred H. Albee, New York: "Restoration of Loss of Bone from Gunshot Wounds."

These papers were discussed by Dr. Joseph R. Eastman, Indianapolis, and Colonel Dunham, Australia.

Dr. Vernon C. David, Chicago, read a paper on "War Injuries of Joints." Discussed by Drs. Arthur M. Shipley, Baltimore; Burton J. Lee, New York; Kellogg Speed, Chicago; Joseph A. Blake, New York, and Fred H. Albee, New York.

Dr. Harvey Cushing, Boston, read a paper on "Brain Injuries."

Dr. George W. Crile, Cleveland, read a paper on "Abdominal Injuries."

SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY

Wednesday, June 11—Morning

The section was called to order at 9:05 by the chairman, Dr. Thomas J. Watkins, Chicago.

Dr. Reuben Peterson was elected delegate to the House of Delegates as substitute for Dr. F. F. Simpson, Pittsburgh, absent in Europe.

Dr. Thomas J. Watkins, Chicago, read the chairman's address, entitled "Progress in Gynecology and Abdominal Surgery." No discussion.

Dr. Samuel M. D. Clark, New Orleans, read a paper on "Analysis of Fifty Cases of Uterine Bleeding from Causes Other than Malignancy or Myoma Treated by Radium."

Dr. John G. Clark, Philadelphia, read a paper on "Treatment of Myoma Uteri with Radium."

These two papers were discussed by Drs. H. C. Bailey, New York; Ernest C. Samuel, New Orleans; Arthur H. Curtis, Chicago; Edward H. Richardson, Baltimore; Roy Lee Brown, New York; John Osborn Polak, Brooklyn; Henry Schmitz, Chicago; Samuel M. D. Clark, New Orleans, and John G. Clark, Philadelphia.

On motion by Dr. J. Riddle Goffe, New York, the recommendation was made to the House of Delegates that guests whose names were presented to the section be elected to honorary membership of the American Medical Association. Seconded and carried.

Dr. Arthur Stein, New York, read a paper on "The Results in Over One Hundred Operations for Uterine Myoma (Operative Versus Roentgen-Ray Treatment)." Discussed by Drs. George E. Pfahler, Philadelphia; J. Riddle Goffe, New York; J. B. DeLee, Chicago; Thomas S. Cullen, Baltimore; Henry Schmitz, Chicago; Peter B. Salatich, New Orleans; Roy Lee Brown, New York; C. N. Cowden, Nashville, Tenn.; Miles F. Porter, Fort Wayne, Ind., and Arthur Stein, New York.

Dr. Chalfant, appointed temporarily Drs. C. Jeff Miller, New Orleans; John Osborn Polak, Brooklyn; Henry P. Newman, San Diego, Calif., on the Executive Committee.

Dr. J. Riddle Goffe offered a resolution, requesting the House of Delegates to approve a committee of the section to take action concerning the international congress of gynecologists and obstetricians, which was referred to the House of Delegates.

Dr. George Gray Ward, Jr., New York, read a paper on "The Teaching Function of the Hospital: With Especial Reference to Gynecology." Discussed by Drs. R. M. Harbin, Rome, Ga.; Isaac S. Stone, Washington, D. C.; John Osborn Polak, Brooklyn; Henry P. Newman, San Diego, Calif.; C. E. Cantrell, Greenville, Texas; J. L. Bubis, Cleveland; J. H. Carstens, Detroit, and George Gray Ward, Jr., New York.

Dr. Emil Ries, Chicago, read a paper on "Alternating, Periodic Swellings of the Ovary." Discussed by Drs. Emil Novak, Baltimore; Alfred Baker Spalding, San Francisco; Peter B. Salatich, New Orleans, and Emil Ries, Chicago.

Thursday, June 12—Morning

The section was called to order at 9 o'clock by Dr. John W. Keefe, Providence, R. I.

Dr. Peter B. Salatich, New Orleans, read a paper on "Uterine Retrodisplacement as a Cause of Reflex Neuroses." Discussed by Drs. E. E. Montgomery, Philadelphia; Charles Ober Kepler, Boston; Emil Novak, Baltimore; Rufus B. Hall, Cincinnati; J. Henry Carstens, Detroit; Isaac S. Stone, Washington, D. C., and Peter B. Salatich, New Orleans.

Dr. J. Henry Carstens, Detroit, read a paper on "The Desirability of Preventing Sterilization in Young Women When Operating for Tuberculous Peritonitis." Discussed by Drs. J. Shelton Horsley, Richmond, Va., and J. Henry Carstens, Detroit.

Dr. Henry P. Newman, San Diego, Calif., read a paper on "The Specialty of Obstetrics." Discussed by Drs. Edward P. Davis, Philadelphia; Gustav E. Zinke, Cincinnati; John F. Moran, Washington, D. C.; H. O. Marcy, Boston; Arthur Stein, New York, and Henry P. Newman, San Diego, Calif.

Dr. Joseph B. DeLee, Chicago, read a paper on "The Newer Methods of Cesarean Section: Their Indications: Results in Forty Cases." Discussed by Drs. James W. Markoe, New York; John Osborn Polak, Brooklyn; Bertha Van Hoosen, Chicago; Gustav E. Zinke, Cincinnati, and Joseph B. DeLee, Chicago.

Dr. Jennings C. Litzenberg, Minneapolis, read a paper on "A Clinical Study of the Treatment of Dysmenorrhea." Discussed by Drs. Emil Novak, Baltimore, and Jennings C. Litzenberg, Minneapolis.

Dr. Frank W. Lynch, San Francisco, read a paper on "Etiology and Treatment of Pernicious Nausea and Vomiting of Pregnancy." Discussed by Drs. Alfred Baker Spalding, San Francisco; Elnora C. Folkmar, Washington, D. C., and Frank W. Lynch, San Francisco.

Dr. Alfred C. Beck, Brooklyn, read a paper on "The Treatment of Abdominal Pregnancy After the Fifth Month." No discussion.

Dr. John Gardiner, Toledo, Ohio, read a paper on "Aspiration and Pressure Treatment of Unopened Mammary Abscess (Puerperal)". Discussed by Drs. Richard C. Norris, Philadelphia; Peter B. Salatich, New Orleans, and John Gardiner, Toledo, Ohio.

Friday, June 13—Morning

The section was called to order at 9 o'clock by the chairman.

The following officers were elected: chairman, Dr. Reuben Peterson, Ann Arbor, Mich.; vice chairman, Dr. Francis Reder, St. Louis; secretary, Dr. Sidney A. Chalfant, Pittsburgh; delegate, Dr. Lewis S. McMurtry, Louisville, Ky.; alternate, Dr. Rufus B. Hall, Cincinnati.

The secretary presented a report of a meeting of section secretaries held in Chicago which presented a number of standing rules for conducting the work of the section. On motion, the report, together with the standing rules, was adopted as a whole.

Dr. Donald Guthrie, Sayre, Pa., read a paper on "Trendelenburg Ether Anesthesia in Pelvic Surgery." Discussed by Drs. John Osborn Polak, Brooklyn; Albert J. Ochsner, Chicago; Donald C. Balfour, Rochester, Minn., and Donald Guthrie, Sayre, Pa.

Dr. Robert E. Farr, Minneapolis, read a paper on "Abdominal Surgery Under Local Anesthesia." Discussed by Drs. Penn-Gaskell Skillern, Jr., Philadelphia; C. N. Cowden, Nashville, Tenn.; J. A. Ruben, Pittsburgh; A. C. Scott, Temple, Texas, and Robert E. Farr, Minneapolis.

Dr. Donald C. Balfour, Rochester, Minn., read a paper on "The Efficiency of Surgical Treatment in the Bleeding Type of Gastric and Duodenal Ulcer." Discussed by Drs. Raymond P. Sullivan, Brooklyn, and Alfred A. Strauss, Chicago.

Dr. J. Shelton Horsley, Richmond, Va., read a paper on "A New Operation for Duodenal and Gastric Ulcers." The discussion of the previous paper was continued in connection with the discussion of Dr. Horsley's paper by Drs. J. B. Blake, Boston; Alfred A. Strauss, Chicago; John T. Bottomley, Boston; George Goodhue, Dayton, Ohio; J. J. Gilbride, Philadelphia; Albert J. Ochsner, Chicago; Miles F. Porter, Fort Wayne, Ind.; W. J. Mayo, Rochester, Minn.; Charles A. L. Reed, Cincinnati; Donald C. Balfour, Rochester, Minn., and J. Shelton Horsley, Richmond, Va.

Dr. John H. Gibbon, Philadelphia, read a paper on "The Treatment of Gunshot Wounds of the Abdomen." Discussed by Dr. Evan W. Meredith, Pittsburgh.

Dr. Roland Hazen, Paris, Ill., read a paper on "Rational Surgery of Visceroptosis." Discussed by Drs. Robert T. Morris, New York; J. J. Gilbride, Philadelphia; J. Shelton Horsley, Richmond, Va.; Charles P. Noble, Philadelphia, and Roland Hazen, Paris, Ill.

SECTION ON OPHTHALMOLOGY

Wednesday, June 11—Morning

The section was called to order at 9:20 by the chairman, Dr. Cassius D. Wescott, Chicago.

Dr. Cassius D. Wescott, Chicago, read the chairman's address.

The following papers were read as a symposium on "Refraction":

Dr. Charles P. Emerson, Indianapolis: "The Ophthalmologist and the Physician."

Dr. Walter L. Pyle, Philadelphia: "Necessary but Often Neglected Refinements in the Examination of Ocular Refraction."

Dr. Edwin J. Gardiner, Chicago: "The Present Status of Refraction Work."

Dr. Samuel Theobald, Baltimore: "The Correction of the Muscular Anomalies of the Eye of Only Less Importance Than That of Their Faults of Refraction."

These four papers were discussed by Drs. Edward Jackson, Denver; Albert E. Bulson, Jr., Fort Wayne, Ind.; Thomas B. Holloway, Philadelphia; Dr. Isaac Hartshorne, New York; Alexander Duane, New York; W. W. Kahn, Detroit; Sidney L. Olsho, Philadelphia; John Green, Jr., St. Louis; William H. Wilder, Chicago; G. C. Savage, Nashville, Tenn.; H. B. Lemere, Omaha; Linn Emerson, Orange, N. J.; Oliver Tydings, Chicago; Dunbar Roy, Atlanta, Ga.; A. E. Davis, New York; Charles P. Emerson, Indianapolis; Walter L. Pyle, Philadelphia; Edwin J. Gardiner, Chicago, and Samuel Theobald, Baltimore.

Wednesday, June 11—Afternoon

The section was called to order at 2 o'clock by the chairman.

There was an exhibition of new instruments and appliances by Drs. David W. Wells, Boston; A. S. Green, San Francisco; John Green, Jr., St. Louis; J. O. McReynolds, Dallas, Texas, and Allen Greenwood, Boston.

Dr. Allen Greenwood, Boston, read a paper on "The Organization and Activities of the Ophthalmic Service in the American Expeditionary Forces." Discussed by Drs. G. E. de Schweinitz, Philadelphia; James Bordley, Jr., Baltimore; E. C. Ellett, Memphis, Tenn.; George S. Derby, Boston; Walter R. Parker, Detroit; Lee Masten Francis, Buffalo; Nelson Miles Black, Milwaukee, and Allen Greenwood, Boston.

Dr. George S. Derby, Boston, read a paper on "The Control of Trachoma Among the Alien Labor Companies of the British and American Expeditionary Forces." Discussed by Drs. Allen Greenwood, Boston, and George S. Derby, Boston.

Dr. F. Park Lewis, Buffalo, read a paper on "Group Study, a Necessity in Ophthalmic Research." Discussed by Drs. Walter R. Parker, Detroit; Alexander Duane, New York; Albert E. Bulson, Jr., Fort Wayne, Ind.; Richard J. Tivnen, Chicago; Oliver Tydings, Chicago; George S. Derby, Boston; G. H. Price, Nashville, Tenn., and F. Park Lewis, Buffalo.

Dr. Edward Jackson, Denver, read a paper on "Daylight Illumination of Interiors." Discussed by Drs. Nelson Miles Black, Milwaukee; W. B. Lancaster, Boston, and Edward Jackson, Denver.

Dr. Robert Blue, Chicago, read a paper on "Family Degeneration of the Macula Lutea." Discussed by Drs. Samuel D. Risley, Philadelphia; William Zentmayer, Philadelphia; Marcus Feingold, New Orleans, and Robert Blue, Chicago.

Thursday, June 12—Morning

The section was called to order by the chairman at 9:05.

The following officers were elected: chairman, Dr. Allen Greenwood, Boston; vice chairman, Dr. Nelson M. Black, Milwaukee; secretary (for three years), Dr. George S. Derby, Boston; delegate, Dr. Lee Masten Francis, Buffalo.

The report of the Committee on Knapp Testimonial Fund was presented by Dr. Bulson.

The report of the Committee on Ophthalmic Examinations was presented by Dr. Edward Jackson, Denver.

On motion duly seconded and carried, preambles and resolutions were adopted authorizing the appointment of a committee from the section to cooperate with similar committees from the American Ophthalmological Society and from the American Academy of Ophthalmology and Oto-Laryngology for the purpose of considering the advisability of arranging for the International Congress of Ophthalmology to be held in the United States.

Drs. Martin Cohen and Isaac Levin, New York, presented a paper on "The Action of Radium on Cataracts." Discussed by Drs. Isaac Levin, New York; Allen Greenwood, Boston; E. L. Jones, Cumberland, Md.; John E. Weeks, New York; F. Park Lewis, Buffalo; S. D. Ridley, Philadelphia; G. C. Savage, Nashville, Tenn.; A. S. Green, San Francsico; Edward Jackson, Denver; S. Lewis Ziegler, Philadelphia, and Martin Cohen, New York.

Action was taken declaring that the Section on Ophthalmology of the American Medical Association recommends that frames with circular lenses be furnished with some device to prevent rotation of the lenses in their frames, a copy to be transmitted to the proper officials of the Senate and House of Representatives at Washington.

Dr. Arthur G. Bennett, Buffalo, read a paper on "Immediate Capsulotomy in the Extraction of Senile Cataract." Discussed by Drs. Harry Woodruff, Joliet, Ill.; F. Park Lewis, Buffalo; Derrick T. Vail, Cincinnati; Edward Jackson, Denver; Walter R. Parker, Detroit, and Arthur G. Bennett, Buffalo.

Dr. S. Lewis Ziegler, Philadelphia, read a paper on "Adventitious Hyaloid Membrane Following Operation for Secondary Cataract." Discussed by Drs. Alexander Duane, New York; George E. de Schweinitz, Philadelphia; William T. Davis, Washington, D. C.; Oliver Tydings, Chicago, and S. Lewis Ziegler, Philadelphia.

Dr. Arnold Knapp, New York, read a paper on "The Autotoxic Factor in Sympathetic Ophthalmia." Discussed by Drs. Louis F. Love, Philadelphia; George Huston Bell, New York, and S. Lewis Ziegler, Philadelphia.

Dr. William H. Wilder, Chicago, read a paper on "Treatment of Symblepharon and Restoration of the Orbital Socket." Discussed by Drs. George E. de Schweinitz, Philadelphia; John E. Weeks, New York; George B. Jobson, Franklin, Pa.; Harry W. Woodruff, Joliet, Ill., and William H. Wilder, Chicago.

Dr. George Huston Bell, New York, read a paper on "The Rôle of Teeth, Tonsils, and Toxemias of the Intestinal Tract in Relation to Diseases of the Eye." Discussed by Drs. Hiram Woods, Baltimore; John E. Weeks, New York; F. Park Lewis, Buffalo; Clarence Arch Veasey, Spokane, Wash.; M. C. Rose, New York; Frederick F. Teal, Lincoln, Neb.; James J. King, New York; H. B. Lemere, Omaha; Oliver Tydings, Chicago; S. Lewis Ziegler, Philadelphia, and George Huston Bell, New York.

Friday, June 13—Morning

The section was called to order by the chairman at 9:05.

Dr. L. Webster Fox, Philadelphia, read a paper on "A New Operation for the Relief of Conical Cornea." Discussed by Drs. Walter B. Lancaster, Boston; Frederick H. Verhoeff, Boston; William Thornwall Davis, Washington, D. C.; A. S. Green, San Francisco; Oscar Wilkinson, Washington, D. C.; Meyer Wiener, St. Louis; W. C. Posey, Philadelphia; S. Lewis Ziegler, Philadelphia, and L. Webster Fox, Philadelphia.

Dr. A. Edward Davis, New York, read a paper on "Uveitis." Discussed by Drs. George E. de Schweinitz, Philadelphia; E. L. Jones, Cumberland, Md., and A. Edward Davis, New York.

The election of a committee on Award of the Knapp Medal was the next order of business. Drs. Edward Jackson, Denver; Samuel D. Risley, Philadelphia, and G. H. Price, Nashville, Tenn., were selected.

It was recommended that three committees be appointed: a committee of three to report to the section on the standardizing of undergraduate instruction in ophthalmology; a committee of three to report a scale of compensation for ocular injuries, and a committee of five to report on the use of various local anesthetics and on their effects on the eye.

Drs. George E. de Schweinitz, Philadelphia, and Meyer Wiener, St. Louis, read a paper on "(1) Cysticercus of the Vitreous; (2) Congenital Multilocular Cysts in Relation with the Retina, and (3) Anterior Lenticonus: Being a Clinical Communication." Discussed by Drs. Frederick H. Verhoeff, Boston; Alexander Duane, New York; Allen Greenwood, Boston; A. E. Davis, New York; S. D. Risley, Philadelphia; George E. de Schweinitz, Philadelphia, and Meyer Wiener, St. Louis.

Dr. John O. McReynolds, Dallas, Texas, read a paper on "Foreign Bodies Within the Eyeball." Discussed by Drs. William M. Sweet, Philadelphia; R. H. T. Mann, Texarkana, Ark.; John Green, Jr., St. Louis; Edward Jackson, Denver; Allen Greenwood, Boston; Lee M. Francis, Buffalo; George S. Derby, Boston; Oliver Tydings, Chicago, and John O. McReynolds, Dallas, Texas.

Dr. John Green, Jr., St. Louis, read a paper on "The Treatment of Dacryocystitis by Curettage." Discussed by Drs. William R. Thompson, Fort Worth, Texas; S. Lewis Ziegler, Philadelphia; William H. Wilder, Chicago, and John Green, Jr., St. Louis.

Dr. John E. Weeks, New York, read a paper on "Personal Observations Regarding the Treatment of Glaucoma." Discussed by Drs. William Campbell Posey, Philadelphia; E. E. Blaauw, Buffalo; L. Webster Fox, Philadelphia; Walter R. Parker, Detroit, and John E. Weeks, New York.

SECTION ON LARYNGOLOGY, OTOLOGY AND RHINOLOGY

Wednesday, June 11—Morning

The section was called to order at 9:15 a. m. by the chairman, Dr. Lee W. Dean, Iowa City, Iowa.

Dr. Dean read the chairman's address.

The chairman then asked Dr. Francis P. Emerson, Boston, to present Dr. Fernand Lemaitre, authorized representative of the French Government. Dr. Lemaitre was seated on the platform.

Dr. Albert P. Brubaker, Philadelphia, read a paper on "Physiologic Mechanism of Sneezing and Nasal Hydrorrhea."

The chairman then asked Dr. H. P. Mosher, Boston, to present Sir St. Clair Thomson, London, England, accredited representative of the British Medical Society, and to bring him to the platform.

Dr. John A. Thompson, Cincinnati, read a paper on "Nasal Hydrorrhea."

Dr. Greenfield Sluder, St. Louis, read a paper on "Asthma as a Nasal Reflex."

Dr. Harry L. Pollock, Chicago, read a paper on "Sphenopalatine Ganglion Neurosis."

These papers were discussed by Sir St. Clair Thomson, London, England, and by Drs. Wolf Freudenthal, New York; Emil Mayer, New York; Orville H. Brown, Phoenix, Ariz.; Joseph C. Beck, Chicago; Albert P. Brubaker, Philadelphia; John A. Thompson, Cincinnati; Greenfield Sluder, St. Louis, and Harry L. Pollock; Chicago.

The chairman then presented Dr. Frank Rose of the Royal Medical Society of London.

Dr. Seymour Oppenheimer, New York, read a paper on "Disease of the Nasal Accessory Cavities of Children." Discussed by Drs. Charles Gilmore Kerley, New York; J. McTiernan, New York; Emil Mayer, New York; Sir St. Clair Thomson, London, England; I. W. Voorhees, New York; G. W. McKenzie, Philadelphia; Lee W. Dean, Iowa City, Iowa, and Seymour Oppenheimer, New York.

The section, on motion by Dr. Francis P. Emerson, nominated the following men as Honorary Fellows of the American Medical Association: Sir St. Clair Thomson, Fernand Lemaitre and Frank Rose.

The chairman appointed the following nominating committee: Francis P. Emerson, Greenfield Sluder and Joseph C. Beck.

Thursday, June 12—Morning

The section was called to order at 9:05 by the chairman. The chairman announced that, according to the new ruling of the House of Delegates, the election of officers would occur at the last session.

The chairman read a letter from the Council on Pharmacy and Chemistry, urging that this section appoint a committee to report on the use of local anesthetics in nose and throat work. It was moved by Dr. Emil Mayer that the chairman appoint three members on that committee. Motion seconded and carried.

A motion was made by Dr. Eugene R. Lewis that Dr. Dutton Wright be given two minutes in which to present the question of the education of the deaf child. Seconded and carried.

Dr. Wright was accorded an opportunity to address the section.

Dr. Emil Mayer offered a motion recommending that the section appoint a committee of three to study the early education of the deaf child.

The Committee on Legislation Regulating the Sale of Caustic Lye Products then made the following report:

> The committee appreciates the importance of securing legislation enforcing restrictions on the sale of caustic products intended for home use. "Caution" labels would tend to standardize lye products as sold by the grocer and would afford some protection to consumers.
>
> We have made efforts to have this matter formulated for legislative action and have been informed that it was under consideration.
>
> It will be necessary to present case reports of lye poisoning in order to impress the importance of legislation protecting the domestic consumer, and this request will be made to the profession at the proper time.
>
> Thomas Hubbard,
> Chevalier Jackson,
> Hubert Arrowsmith,
> Committee.

A motion was made by Dr. J. F. Barnhill, Indianapolis, that the report be accepted and the committee continued. Motion seconded and carried.

The Committee on Necrology then made its report.

A motion was made by Dr. Eugene Lewis that the report be received and the committee continued, the section receiving the report by standing vote. Carried.

Dr. Meyers, St. Louis, presented an improved lever for pulling the tonsil over the eminence of the inferior maxillary, using a Sluder handle on the Beck instrument.

Dr. Chevalier Jackson, Philadelphia, read a paper on "Arachidic Bronchitis." Discussed by Drs. Edwin E. Graham, Philadelphia; Thomas Hubbard, Toledo, Ohio; J. W. Murphy, Cincinnati; H. P. Mosher, Boston; Fenton B. Turck, New York; Sir St. Clair Thomson, London- England, and Chevalier Jackson, Philadelphia.

Dr. Henry L. Lynah, New York, read a paper on "Influenza Croup." This paper was discussed by Drs. Jesse Bullowa, Charles W. Richardson, Washington, D. C.; Samuel M. Iglauer, Cincinnati; Thomas Hubbard, Toledo, Ohio, and Henry L. Lynah, New York.

Dr. Joseph H. Bryan, Washington, D. C., and Dr. C. Norman Howard, Warsaw, Ind., presented a paper on "The Relation of the Ear and Accessory Sinuses to Influenza During the Recent Epidemic, as Observed at the Walter Reed Hospital, Takoma Park, D. C." Discussed by Drs. Weider, Philadelphia; John B. Potts, Omaha; M. F. Arbuckle, St. Louis; J. M. McTiernan, New York; B. Alexander Randall, Philadelphia; Sir St. Clair Thomson, London, England, and Joseph H. Bryan, Washington, D. C.

Dr. Charles W. Richardson, Washington, D. C., read a paper on "Organization of the Section of Defects of Hearing and Speech, Division of Physical Reconstruction, Office of the Surgeon-General, U. S. Army." Discussed by Drs. John M. Ingersoll, Cleveland; H. P. Mosher, Boston; Elmer E. Kenyon, Chicago, and Charles W. Richardson, Washington, D. C.

Dr. Thomas J. Harris, New York, read a paper on "The Present Status of Otolaryngology in America, with a Plea for a Standardized Course of Instruction." Discussed by John Bowman, director, American College of Surgeons, and Drs. H. P. Mosher, Boston; D. J. Gibbs-Wishart, Toronto, Canada; Coakley, New York; Joseph C. Beck, Chicago; Sir St. Clair Thomson, London, England, and Thomas J. Harris, New York.

Dr. Greenfield Sluder exhibited a guillotine for the removal of tonsils—an instrument presented last year. A lever gives added power, and the blade has been bent and put into a sleeve.

FRIDAY, JUNE 13—MORNING

The section was called to order at 9 o'clock by the chairman.

Following some announcements, the secretary read the standing rules agreed on at a conference of the secretaries of the sections and reported to the House of Delegates by the Council on Scientific Assembly (see this report for these rules). On motion duly seconded and carried, these standing rules were adopted.

The chairman appointed as the Committee on the Use of Local Anesthetics in Nose and Throat Work, Emil Mayer, New York; Ross W. Skillern, Philadelphia, and Robert Sonnenschein, Chicago.

Dr. Thomas J. Harris, New York, moved that the Committee on the Education of the Deaf Child be made a permanent committee to consider the question of the education of the deaf child. Seconded and carried.

Dr. H. P. Mosher then presented the report of the Committee on Graduate and Undergraduate Teaching in Laryngology.

A motion was made by Dr. Thomas J. Harris that the report be received. Seconded and carried.

A motion was made by Dr. Thomas J. Harris that the recommendations of the committee presenting the above report be approved. This motion was seconded; Dr. James Lawton Hiers, Savannah, Georgia, spoke to the motion, and it carried.

The chairman appointed as the Committee on the Education of the Deaf Child, Drs. Charles W. Richardson, Washington, D. C.; Elmer E. Kenyon, Chicago, and M. A. Goldstein, St. Louis.

The following officers were elected: Chairman, Joseph C. Beck, Chicago; vice chairman, George M. Coates, Philadelphia; secretary (three years), William B. Chamberlin, Cleveland; delegate, John F. Barnhill, Indianapolis; alternate, Thomas Darmody, Denver.

Dr. Wells P. Eagleton, Newark, N. J., read a paper on "Cerebellar Abscess." Discussed by Dr. George F. Cott, Buffalo; Prof. Fernand Lemaitre, France; Drs. Ewing W. Day, Pittsburgh; Edward J. Bernstein, Detroit; Joseph C. Beck, Chicago, and Wells P. Eagleton, Newark, N. J.

Dr. John B. Potts, Omaha, read a paper on "Mastoidectomy: Postoperative Treatment by Carrel-Dakin Solution and Results." Discussed by Drs. Ewing W. Day, Pittsburgh; Arthur C. Stokes, Omaha; Francis P. Emerson, Boston; C. J. Swan, Evanston, Ill.; Wendell C. Phillips, New York; Edward J. Bernstein, Detroit, and John B. Potts, Omaha.

Sir St. Clair Thomson, London, England, read a paper on "Tranquil Tracheotomy by Injecting Cocain Within the Windpipe." Discussed by Drs. Frank C. Rose, London, England, and Frederick R. Waldron, Ann Arbor, Mich.; Prof. Fernand Lemaitre, and Drs. Otto Glogau, New York; M. F. Arbuckle, St. Louis, and Sir St. Clair Thomson, London, England.

Dr. Ross H. Skillern, Philadelphia, read a paper on "Some Experiences of a Commanding Officer of a Base Hospital in France." Discussed by Dr. George M. Coates, Philadelphia.

The chairman then introduced the newly elected chairman, Dr. Joseph C. Beck, who took the chair.

Dr. Francis P. Emerson moved a rising vote of thanks to Sir St. Clair Thomson, Prof. Fernand Lemaitre, and Dr. Frank C. Rose, not only for their presence, but for their valued contributions to the program, and expressed the hope that this section may be favored with their presence in the future. Seconded and carried.

Dr. Charles W. Richardson moved that the section express its gratitude to the retiring chairman, Dr. Lee W. Dean, for the efficient manner in which he presided during the sessions and for the particularly successful issue which was brought about by his management of the section. Seconded and carried.

SECTION ON DISEASES OF CHILDREN

WEDNESDAY, JUNE 11—AFTERNOON

The meeting was called to order at 2:30 by the chairman, Dr. Franklin P. Gengenbach, Denver.

Dr. Franklin P. Gengenbach read the chairman's address entitled "Our Section in the War Work."

The following resolution was adopted:

WHEREAS, Investigation by a committee of the Section on Diseases of Children of the American Medical Association shows that there is a great deal of confusion in the operation of the federal regulations concerning infant and child welfare in this country; and

WHEREAS, It further appears that this unfortunate condition is largely due to the lack of cooperation for one reason or another between the medical profession and those governmental agencies charged with this work; and

WHEREAS, It also appears that the control of the medical aspect of this vital matter is being assumed by lay people to the exclusion of the medical profession, therefore, by and for the Section on Diseases of Children of the American Medical Association, be it

Resolved, That it is earnestly requested that the Council on Health and Public Instruction give this matter serious attention, and that it shall confer with a committee appointed from the Section on Diseases of Children to consider carefully the matter and to report at the next annual meeting. (Not submitted to the House of Delegates.)

Dr. James D. Love, Jacksonville, Fla., spoke on the arrangement of the section meetings. Dr. Emanuel C. Fleischner, San Francisco, replied to Dr. Love's suggestions.

Dr. Anna E. Rude, Washington, D. C., read a paper on "The 'Victory' of Children's Year." Discussed by Sir Arthur Newsholme, England.

Dr. Frank C. Neff, Kansas City, Mo., read a paper on "The Pediatrician at Home During the War." Discussed by Drs. John M. Dodson, Chicago; Percival J. Eaton, Pittsburgh; S. M. Hamill, Philadelphia; Ethel B. Davis, Chicago; H. F. Helmholz, Chicago; Anna E. Rude, Washington, D. C., and Frank C. Neff, Kansas City, Mo.

Dr. Clifford G. Grulee, Chicago, read a paper on "The Work of the Children's Bureau of the American Red Cross in Lyons, France." Discussed by Dr. Frank H. Lamb, Cincinnati.

Dr. William McKim Marriott, St. Louis, read a paper on "The Artificial Feeding of Athreptic Infants." Discussed by Drs. Fritz Talbot, Boston; Alfred F. Hess, New York; J. C. Griffith, Philadelphia; C. G. Kerley, New York; J. H. Kerley, New York; H. F. Helmholz, Chicago; Louis Hill, Boston; Thomas C. McCleave, Oakland, Calif., and William McKim Marriott, St. Louis.

Dr. Alfred F. Hess, New York, read a paper on "The Deleterious Effect of Alkalinization of Infants' Food." Discussed by Drs. Harry Lowenburg, Philadelphia; Julius H. Hess, Chicago; C. G. Kerley, New York; J. C. Griffith, Philadelphia; St. George T. Grinnan, Richmond, Va.; Joseph Grover, Boston; Louis Hill, Boston; Ethel B. Davis, Chicago; Emanuel C. Fleischner, San Francisco; F. C. Neff, Kansas City, Mo., and Alfred F. Hess, New York.

A motion made by Dr. J. C. Griffith, Philadelphia, that all reference by name to any proprietary food as advertised to the laity be eliminated from the record, was discussed by Drs. A. F. Hess, New York; J. C. Griffith, Philadelphia, and Harry Lowenburg Philadelphia, and carried.

THURSDAY, JUNE 12—MORNING

The meeting was called to order at 9:15 by the chairman.

A motion was passed that the resolution passed at the last session be returned to the committee.

Dr. Walter R. Ramsey, St. Paul, spoke on his work in France. Discussed by Dr. Julius P. Sedgwick, Minneapolis.

Dr. John A. Foote, Washington, D. C., read a paper on "Hemangio-Endotheliosarcoma of the Liver." No discussion.

Drs. William Herrick, New York, and Arthur M. Dannenberg, Philadelphia, presented a paper on "Observations on the Spinal Fluid of Acute Disease."

Dr. Abraham Levinson, Chicago, read a paper on "Quantitative and Qualitative Changes in the Cerebrospinal Fluid and Their Significance."

These two papers were discussed by Drs. Charles G. Kerley, New York; Isaac A. Abt, Chicago; Walter R. Ramsey, St. Paul; Alfred P. Hess, New York; H. L. F. Locke, Hartford, Conn.; Herman Schwartz, New York; F. B.

Talbot, Boston; W. R. Sissner, Boston; W. L. Moss, New Haven, Conn.; Arthur M. Dannenberg, Philadelphia; William W. Herrick, New York, and Abraham Levinson, Chicago.

Dr. Rowland G. Freeman, New York, read a paper on "Pneumonia in Infancy and Childhood Without Physical Signs." Discussed by Drs. Walter R. Ramsey, St. Paul; Ernest Zueblin, Cincinnati; Charles G. Kerley, New York; Laurence R. DeBuys, New Orleans; J. S. Wall, Washington, D. C.; G. R. Pisek, New York; Louis Fischer, New York, and Rowland G. Freeman, New York.

Dr. Julius H. Hess, Chicago, read a paper on "A Comparative Study of the Early and Late Secondary Complications of Influenza and Influenzal Pneumonia as Seen in the Army, with Those of Infants and Children in Civil Practice."

Drs. Herman Schwartz and Harry Wessler, New York, presented a paper on "Abscess of the Lung in Children."

These two papers were discussed by Drs. Thomas C. McCleave, Oakland, Calif.; William Weston, Columbia, S. C.; H. M. McClanahan, Omaha; Ernest Zueblin, Cincinnati; Ellis Bonime, New York; Langley Porter, San Francisco; Louis Fischer, New York; Julius H. Hess, Chicago, and Herman Schwartz, New York.

Friday, June 13—Afternoon

The meeting was called to order at 2 o'clock by the chairman.

Dr. Richard Cole Newton, Montclair, N. J., read a paper on "Some Clinical Experience in the Treatment of Children with Tuberculin." Discussed by Drs. Francis M. Pottenger, Los Angeles; Ellis Bonime, New York; Fritz B. Talbot, Boston; Abraham Levinson, Chicago, and Richard Cole Newton, Montclair, N. J.

Dr. Emanuel C. Fleischner, San Francisco, read the report of the Advisory War Committee of the Section on Diseases of Children. Discussed by Drs. Thomas C. McCleave, Oakland, Calif.; Isaac A. Abt, Chicago, and Laurence R. De Buys, New Orleans. A motion was passed that the committee be continued.

The following officers were elected: chairman, Dr. Fritz B. Talbot, Boston; vice chairman, Dr. Julius H. Hess, Chicago; secretary, Dr. Emanuel C. Fleischner, San Francisco (reelected), and delegate, Dr. Isaac A. Abt.

Dr. Charles Hendee Smith, New York, read a paper on "Recent Development in Outpatient Work." Discussed by Drs. W. L. Moss, New Haven, Conn.; Isaac A. Abt, Chicago; Harry Lowenberg, Philadelphia; Langley Porter, San Francisco, and Dr. Charles Hendee Smith, New York.

Dr. Langley Porter, San Francisco, read a paper on "Retrospect of Fifteen Years' Experience in the Treatment of Hypertrophic Pyloric Obstruction in Infants." Discussed by Drs. H. F. Helmholz, Chicago; Frank C. Neff, Kansas City, Mo.; Harry Lowenberg, Philadelphia; Laurence R. De Buys, New Orleans, and Langley Porter, San Francisco.

Dr. Henry D. Chapin, New York, read a paper on "Chemical Examination of the Blood of Children." Discussed by Dr. Charles G. Kerley, New York.

Dr. Louis Fischer, New York, read a paper on "The Abuse of Cathartics and Laxatives in Infancy and Childhood." Discussed by Drs. W. L. Moss, New Haven, Conn.; H. L. F. Locke, Hartford, Conn.; Laurence R. De Buys, New Orleans; Richard Cole Newton, Montclair, N. J.; Lewis W. Elias, Asheville, N. C.; F. H. Allen, Holyoke, Mass.; Julius H. Hess, Chicago; Walter R. Ramsey, St. Paul, and J. M. Miller, Atlantic City, N. J.

Dr. Fritz B. Talbot, Boston, read a paper on "The Analysis of Human Milk: The Technic of Obtaining Samples and the Interpretation of Results." Discussed by Drs. John Foote, Washington, D. C.; James D. Love, Jacksonville, Fla., and Fritz B. Talbot, Boston.

Dr. E. Bosworth McCready, Pittsburgh, read a paper on "The Nervous Child and His Management." Discussed by Drs. Percival J. Eaton, Pittsburgh; Richard Cole Newton, Montclair, N. J.; W. L. Moss, New Haven, Conn.; Harold B. Wood, Providence, R. I., and E. Bosworth McCready, Pittsburgh.

Drs. Laurence R. De Buys, Maude Loeber and Foster M. Johns, New Orleans, presented a paper on "A Study in a Foundling Institution to Determine the Incidence of Congenital Syphilis." Discussed by Drs. Harold B. Wood, Providence, R. I.; Walter R. Ramsey, St. Paul; J. McKey, Philadelphia, and Laurence R. De Buys, New Orleans.

SECTION ON PHARMACOLOGY AND THERAPEUTICS

Wednesday, June 11—Afternoon

The meeting was called to order at 2 p. m. by the chairman, Dr. W. A. Bastedo, New York. In the absence of the secretary, Dr. Cary Eggleston, New York, because of his having met the week before with a serious accident, Dr. R. A. Hatcher, New York, was elected secretary pro tem.

Dr. Bastedo read the Chairman's address, entitled "Suggestions for an Ideal Course in Therapeutics."

Dr. Lester J. Unger, New York, read a paper on "Therapeutic Aspect of Blood Transfusion." Discussed by Drs. E. W. Peterson, New York; Frank W. Hartman, Washington, D. C.; Lester Neuman, Washington, D. C., and Lester J. Unger, New York.

The chairman then introduced Dr. P. Nolf, Brussels, Belgium, who read a paper on "Therapeutic Observations in Bacillary Dysentery." Discussed by Drs. Solomon Solis Cohen, Philadelphia, and P. Nolf, Brussels, Belgium.

Dr. Charles C. Lieb, New York, read a paper on "The Action of Anthracene Cathartics on the Isolated Uterus."

Dr. William DeB. MacNider, Chapel Hill, N. C., read a paper on "A Study of Acute Mercuric Chlorid Intoxication in Normal and in Naturally Nephropathic Dogs." Discussed by Drs. Jacob Rosenbloom, Pittsburgh; Ernest Zueblin, Cincinnati, and William DeB. MacNider, Chapel Hill, N. C.

Thursday, June 12—Morning

The meeting was called to order by the chairman at 9 a. m.

The following officers were elected: chairman, George W. McCoy, Washington, D. C.; vice chairman, Leonard G. Rountree, Minneapolis; secretary, Cary Eggleston, New York (continued); delegate, W. A. Bastedo, New York.

The chairman presented a communication from the U. S. Public Health Service calling attention to a bill regulating vivisection, which was introduced in Congress June 2, and appointed a committee consisting of Drs. G. W. McCoy, Washington, D. C.; A. D. Hirschfelder, Minneapolis, and Robert A. Cooke, New York, to consider the bill and to present a recommendation for action by the section.

Dr. Lambert Ott, Philadelphia, read a paper on "Forty Years' Observation Among Beer, Wine and Whisky Drinkers." Discussed by Drs. Charles A. Rosewater, Newark, N. J.; Solomon Solis Cohen, Philadelphia, and Lambert Ott, Philadelphia.

Dr. Orville H. Brown, Phoenix, Ariz., read a paper on "The Principles of the Treatment of Asthma." Discussed by Drs. S. A. Knopf, New York, and Solomon Solis Cohen, Philadelphia.

Dr. Robert A. Cooke, New York, read a paper on "Allergy in Drug Idiosyncrasy." Discussed by Drs. Lambert Ott, Philadelphia, and Robert A. Cooke, New York.

Dr. Henry Rawle Geyelin, New York, read a paper on "Results in the Modern Treatment of Diabetes." Discussed by Drs. Alfred Stengel, Philadelphia; Jacob Rosenbloom, Pittsburgh; Philip S. Roy, Washington, D. C.; H. O. Mosenthal, New York; E. P. Joslin, Boston; L. F. Kebler, Washington, D. C.; L. G. Heyn, Cincinnati, and C. M. Grigsby, Dallas, Texas.

Dr. R. A. Hatcher, New York, read a paper on "A Further Contribution to the Pharmacology of the Local Anesthetics." Discussed by Dr. David I. Macht, Baltimore.

Dr. David I. Macht, Baltimore, read a paper on "A Therapeutic Study of Benzyl Benzoate: Pharmacologic and Clinical." Discussed by Drs. Douglas Vanderhoof, Richmond, Va.; W. A. Bastedo, New York, and David I. Macht, Baltimore.

Friday, June 13—Afternoon

A joint meeting was held with the Sections on Pathology and Physiology and Preventive Medicine and Public Health.

The meeting was called to order at 2 p. m. by Dr. W. A. Bastedo, New York, chairman of the Section on Pharmacology and Therapeutics.

The following papers were read as a symposium on "Influenza":

Dr. Milton J. Rosenau, Boston: "Experiments on Volunteers to Determine the Mode of Spread of Influenza."

Dr. Wade H. Frost, Washington, D. C.: "Epidemiology of Influenza."

Dr. William H. Park, New York: "The Bacteriology of Influenza and Its Complications."

Dr. William G. MacCallum, Baltimore: "The Pathology of Influenza."

These four papers were discussed by Drs. Augustus Wadsworth, Albany, N. Y.; Anna W. Williams, New York; Edwin R. LeCount, Chicago; Henry Albert, Iowa City, Iowa; Alexander Lambert, New York, and Harold B. Wood, Providence, R. I.

Dr. C. D. Selby, Toledo, Ohio, proposed a resolution urging Congress to appropriate $1,500,000 for the investigation of influenza, this sum to be available to July 1, 1922. This resolution was seconded and carried.

(Not submitted to the House of Delegates.)

The symposium on "Influenza" was resumed:

Dr. Lewis A. Conner, New York: "The Symptoms and Complications of Influenza."

Dr. Edward C. Rosenow, Rochester, Minn.: "Further Studies on Prophylactic Inoculation in Influenza and Pneumonia."

Dr. George W. McCoy, Washington, D. C.: "Present Status of Prophylactic Vaccination Against Influenza."

Dr. Henry F. Stoll, Hartford, Conn.: "Value of Convalescent Blood and Serums in the Treatment of Influenzal Pneumonia."

Dr. James B. Herrick, Chicago: "The Treatment of Influenza by Means Other Than Vaccine and Serums."

These five papers were discussed by Drs. Frank W. Hartman, U. S. Navy; Solomon Solis Cohen, Philadelphia; H. I. Goldstein, Camden, N. J.; Frederick T. Lord, Boston; Albert E. Roussel, Philadelphia; Will Walter, Chicago; M. K. Wylder, Albuquerque, N. M.; William C. Woodward, Boston; C. C. Browning, Los Angeles; H. H. Koons, Los Angeles; W. A. Bastedo, New York; George W. McCoy, Washington, D. C.; Edward C. Rosenow, Rochester, Minn., and James B. Herrick, Chicago.

SECTION ON PATHOLOGY AND PHYSIOLOGY

Wednesday, June 11—Afternoon

The section was called to order at 2:15 by the chairman, Dr. Francis Carter Wood, New York.

Dr. Francis Carter Wood, New York, read the chairman's address, entitled "The Relation of Pathology to Practice."

Dr. Frederic Lee, New York, read a paper on "The Human Machine in the Factory." Discussed by Drs. F. P. Gay, Berkeley, Calif.; Eliza M. Mosher, Brooklyn; E. R. LeCount, Chicago; John Bryant, Boston, and Frederic Lee, New York.

Dr. Louis I. Harris, New York, read a paper on "Clinical Types of Occupational Diseases and the Study of Methods for Their Prevention." Discussed by Dr. Frederic Lee, New York.

Dr. B. H. Ransom, Washington, D. C., read a paper on "A Newly Recognized Cause of Pulmonary Disease—Ascaris Lumbricoides." Discussed by Drs. Theodore Zbinden, Toledo, Ohio; Henry Albert, Iowa City, Iowa; C. C. Bass, New Orleans, and B. H. Ransom, Washington, D. C.

Dr. Kenneth M. Lynch, Charleston, S. C., read a paper on "The Periodicity of Microfilaria." No discussion.

Dr. Sarah R. Kelman, Iowa City, Iowa, read a paper on "Experimental Emphysema." Discussed by Drs. J. G. M. Bullowa, New York; Baldwin H. Lucke, Philadelphia; Meyer A. Rabinovitz, Brooklyn; Henry Albert, Iowa City, Iowa; Robert A. Keilty, Danville, Pa.; Jesse W. Smith, Charleston, S. C.; E. C. Rosenow, Rochester, Minn.; A. A. Epstein, New York, and Sarah R. Kelman, Iowa City, Iowa.

The officers and members of the section approved the following list of applications for associate fellowship in the American Medical Association: E. Thompson Bell, Minneapolis; Ross G. Harrison, New Haven, Conn.; Frank W. Lacy, Las Animas, Colo.; Frederic S. Lee, New York; Davenport Hooker, New Haven, Conn.; Milton C. Winternitz, New Haven, Conn.; Leila De Ette Jackson, Chicago; William H. Welker, Chicago; Joseph Erlanger, St. Louis; Roy Graham Hoskins, Washington, D. C.; W. C. A. MacKinlay, New Haven, Conn., and Valerian Parker, Hartford.

It was moved, seconded and carried that the delegates representing the medical profession of the countries allied with the United States in the world war and the other invited guests from foreign countries be nominated for honorary fellowship.

Thursday, June 12—Morning

The meeting was called to order at 9:30 by the chairman.

Dr. Eli K. Marshall, Jr., Baltimore, read a paper on "Mustard Gas."

Dr. Frank P. Underhill, New Haven, Conn., read a paper on "The Physiology and Experimental Treatment of Acute Poisoning with the Lethal War Gases."

Dr. Milton C. Winternitz, New Haven, Conn., read a paper on "Anatomic Changes in the Respiratory Tract Initiated by Irritating Gases."

These three papers were discussed by Drs. A. M. Puppenheimer, New York; E. R. LeCount, Chicago; W. M. L. Coplin, Philadelphia; H. E. Robertson, Minneapolis; Francis C. Wood, New York; Eli K. Marshall, Jr., Baltimore, and Frank P. Underhill, New Haven, Conn.

Dr. Frank C. Mann and Dr. K. Kawamura, Rochester, Minn., presented a paper on "Duodenectomy: A Preliminary Report." Discussed by Drs. W. C. MacCarty, Rochester, Minn.; W. M. L. Coplin, Philadelphia; Francis Carter Wood, New York, and Dr. Frank C. Mann, Rochester.

Drs. Howard T. Karsner, L. Rothschild and E. C. Crump, Cleveland, presented a paper on "Clinical Diagnosis as Compared with Necropsy Findings in Six Hundred Cases." Discussed by Drs. F. C. Wood, New York; W. C. MacCarty, Rochester, Minn.; E. R. LeCount, Chicago; Henry Albert, Iowa City; W. M. L. Coplin, Philadelphia; H. E. Robertson, Minneapolis, and H. T. Karsner.

The following officers were elected: chairman, Dr. Howard T. Karsner, Cleveland; secretary, Dr. J. J. Moore, Chicago (held over from present year); delegate, Dr. E. R. LeCount, Chicago; alternate, Dr. Henry Albert, Iowa City, Iowa.

Friday, June 13—Afternoon

A joint meeting was held with the Sections on Pharmacology and Therapeutics, and Preventive Medicine and Public Health.

SECTION ON STOMATOLOGY

Wednesday, June 11—Morning

The meeing was called to order by the chairman, Dr. Eugene S. Talbot, Chicago.

Dr. Thomas L. Gilmer, Chicago, was appointed to act as vice chairman, in the absence of Dr. Lyons.

Dr. Eugene S. Talbot read the chairman's address, reviewing the section work since its organization. Discussed by Drs. T. L. Gilmer, Chicago; G. V. I. Brown, Milwaukee; M. I. Schamberg, New York; E. A. Bogue, New York, Frederick B. Moorehead, Chicago; W. C. Fisher, New York; Arthur D. Black, Chicago; Charles R. Turner, Philadelphia; Arthur Zentler, New York, and E. S. Talbot, Chicago.

Frederick B. Moorehead, Chicago, read a paper on "Macrocheilia, with Report of Two Cases." Discussed by Drs. Vilray P. Blair, St. Louis; M. I. Schamberg, New York, and Thomas L. Gilmer, Chicago.

Dr. Charles R. Turner, Philadelphia, read a paper on "Teaching the Principles of Maxillofacial Surgery in a Civilian School."

Dr. G. V. I. Brown, Milwaukee, read a paper on "Teaching the Principles of Maxillofacial Surgery in a Military School."

Dr. Rea P. McGee, Denver, read a paper on "The Maxillofacial Surgeon in the Front Line Hospital."

Dr. Ivan Smith, Mishawaka, Ind., read a paper on the "Experience of a Dental Surgeon in a Base Hospital in the Advanced Area."

A committee, consisting of Drs. M. I. Schamberg, New York, chairman; Frederick B. Moorehead, Chicago, and Vilray P. Blair, St. Louis, was appointed to consider the suggestions contained in the chairman's address.

The chairman appointed as a nominating committee: Drs. Thomas L. Gilmer, Chicago; G. V. I. Brown, Milwaukee, and Frederick B. Moorehead, Chicago.

Thursday, June 12—Morning

The meeting was called to order by the chairman.

The secretary, Dr. Arthur D. Black, Chicago, moved that Major Fernand Lemaitre of Paris be nominated to the House of Delegates for Honorary Fellowship in the Association. Seconded and carried.

Dr. Frederick B. Noyes, Chicago, reported that the executive committee had reported favorably on the applications for membership of Drs. C. R. Turner, Philadelphia; B. E. Buell, Chief, Dental Department, U. S. Public Health Service; S. L. Silverman, Atlanta, Ga.; H. C. Hopkins, Washington, D. C., and J. D. Milliken, San Francisco.

The motion was made, seconded and carried that those named be approved for Associate Fellowship.

Dr. George M. Dorrance, Philadelphia, read a paper on "Observations of the Work at Queens' Hospital in England."

Drs. Robert H. Ivy, Milwaukee, and Joseph D. Eby, Washington, D. C., presented a paper on "Reconstruction Work in War Injuries of the Jaws."

Dr. Stewart Ruggles, Portsmouth, Ohio, read a paper on "Experience of a Dental Surgeon in a Base Hospital in a Base Section."

Dr. George W. Schaeffer, Columbus, Ohio, read a paper on "Experience of an Area Consultant in the Zone of the Advance."

Dr. Arthur D. Black, Chicago, introduced Major Fernand Lemaitre of Paris, who expressed his pleasure at being present.

Dr. Henry S. Dunning, New York, read a paper on "Osteoperiosteal Bone Grafts of the Mandible as Performed by the French."

Major Fernand Lemaitre, Paris, addressed the section, using illustrative roentgenograms.

Dr. Herbert A. Potts, Chicago, read a paper on "Experience of an Area Consultant in the Intermediate Section."

Friday, June 13—Morning

The section was called to order by the chairman at 9:45. The following officers were elected: chairman, Dr. Vilray P. Blair, St. Louis; vice chairman, Dr. Henry S. Dunning, New York; secretary, Dr. Arthur D. Black, Chicago; delegate, Dr. William C. Fisher, New York.

Dr. Frank J. Tainter, St. Charles, Mo., read a paper on "Bone Grafting in Jaw Cases."

Drs. Daniel H. Macauly, Jr., and Ernest P. Dameron, Cape May, presented a paper on "Infected Fractures of the Mandible.

Dr. V. H. Kazanjian, Boston, read a paper on "Prosthetic Appliances in Relation to the Surgical Treatment of Wounds of the Face and Jaws."

These three papers were discussed by Drs. Vilray P. Blair, St. Louis; Robert H. Ivy, Milwaukee; C. Waldron, Military Hospital, Ste. Anne de Bellevue, Quebec, Canada, and Fred H. Albee, New York.

An expression of thanks to the medical profession for the opportunity which was offered the dental profession to help out in the European war was made by Dr. Stewart Ruggles, Portsmouth, Ohio.

SECTION ON NERVOUS AND MENTAL DISEASES

Wednesday, June 11—Afternoon

The meeting was called to order at 2 o'clock by the chairman, Dr. Archibald Church, Chicago.

Dr. Archibald Church, Chicago, read the chairman's address, entitled "The Pathology of Cervical Ribs."

The chairman appointed the following members to act as a nominating committee: Drs. Sanger Brown, Chicago; Walter Timme, New York, and W. A. Jones, Minneapolis.

In the absence of two members of the executive committee made up of Drs. George A. Moleen, Denver, Bernard Sachs, New York, and C. Eugene Riggs, St. Paul, the chairman named Drs. T. H. Weisenburg, Philadelphia, and Hugh T. Patrick, Chicago, to act for Drs. Sachs and Riggs.

Dr. Joseph Byrne, New York, read a paper on "The Mechanism of Referred Pain, Hyperalgesia and Alcoholic Injections for the Relief of Neuralgia, with Suggestions for the Surgical Treatment of Injured Nerves." Discussed by Dr. Tom A. Williams, Washington, D. C.

Dr. Walter Timme, New York, read a paper on "A New Polyglandular Compensatory Syndrome." Discussed by Drs. Tom A. Williams, Washington, D. C., and Albert E. Sterne, Indianapolis.

Dr. Theodore H. Weisenburg, Philadelphia, read a paper on "Treatment of War Neurosis."

Dr. Tom A. Williams, Washington, D. C., read a paper on "The Management of War Hysteria."

These two papers were discussed by Drs. Robert McGregor, Saginaw, Mich.; Charles A. Rosewater, Newark, N. J., and Lewis J. Pollock, Chicago.

Dr. Edward E. Mayer, Pittsburgh, read a paper on "The Psychopathology of Amnesia." Discussed by Drs. Joseph Byrne, New York; H. D. Singer, Kankakee, Ill.; W. A. Jones, Minneapolis; Albert E. Sterne, Indianapolis, and Tom A. Williams, Washington, D. C.

Thursday, June 12—Morning

The following officers were elected: chairman, Dr. Elmer E. Southard, Boston; vice chairman, Dr. Arthur S. Hamilton, Minneapolis; secretary, Dr. Charles W. Hitchcock, Detroit; delegate, Dr. Hugh T. Patrick, Chicago.

Dr. Hugh T. Patrick read the following resolution which was unanimously adopted:

> Whereas, At the last session of the American Medical Association, the Section on Nervous and Mental Diseases petitioned the Trustees of the Association to establish a journal devoted to nervous and mental diseases and unanimously passed a resolution endorsing the plan; and
>
> Whereas, The Trustees thereafter did establish the *Archives of Neurology and Psychiatry* and are successfully conducting the same; therefore, be it
>
> *Resolved*, That this section hereby express to the Trustees of the American Medical Association and to the managing editor their appreciation of and thanks for this action.

Dr. Charles K. Mills, Philadelphia, read a paper on "Neurologic and Psychiatric Experiences Illustrative of Real Progress and of Fads and Fallacies in Therapeutics." No discussion.

Dr. Elmer E. Southard, Boston, read a paper on "The Range of the General Practitioner in Psychiatry." Discussed by Dr. E. Stanley Abbot, Belmont, Mass.

Dr. William G. Spiller, Philadelphia, read a paper on "Congenital Tumor (Telangiectasis) and Associated Cerebral Movements." Discussed by Dr. H. H. Hoppe, Cincinnati.

Dr. Leo M. Crafts, Minneapolis, read a paper on "Original Test for the Pathologic Great Toe Sign with Illustrative Cases." Discussed by Dr. George A. Moleen, Denver.

Dr. Tom B. Throckmorton, Des Moines, read a paper on "Clinical Report of a Case of Tumor of the Pons Varolii." Discussed by Drs. H. H. Hoppe and F. W. Langdon, Cincinnati.

Drs. Peter Bassoe and George B. Hassin, Chicago, presented a paper on "The Histologic Changes in the Brain in Lethargic Encephalitis." Discussed by Dr. Max H. Weinberg, Pittsburgh.

Dr. Beverly R. Tucker, Richmond, Va., read a paper on "The Rôle of the Pituitary Gland in Epilepsy." Discussed by Drs. Walter Timme, New York; H. H. Hoppe, Cincinnati; E. B. Angell, Rochester, N. Y.; George A. Moleen, Denver; Albert E. Sterne, Indianapolis, and Irving J. Sands, New York.

FRIDAY, JUNE 13—AFTERNOON

In the absence of the chairman, the meeting was called to order at 2 o'clock by Dr. H. H. Hoppe, Cincinnati.

Dr. Harry H. Drysdale, Cleveland, read a paper on "A Case of Hysterical Hemiplegia Following a Shrapnel Wound of the Scalp, and Presenting Interesting Clinical Features." Discussed by Drs. Alfred Gordon, Philadelphia; Tom A. Williams, Washington, D. C.; Albert E. Sterne, Indianapolis; Lewis J. Pollock, Chicago; Hugh T. Patrick, Chicago; W. S. Lindsay, Topeka, Kan.; Foster Kennedy, New York; Edward E. Mayer, Pittsburgh; Julius Grinker, Chicago, and Harry H. Drysdale, Cleveland.

Dr. Alfred Gordon, Philadelphia, read a paper on "Multiple Neuritis of Toxi-Infectious Origin with Especial Reference to Diabetic Polyneuritis." No discussion.

Dr. George Wilson, Philadelphia, read a paper on "The Resemblance of the Sensory Symptoms of Diphtheritic Multiple Neuritis to those of Anemic Cord Changes." Discussed by Dr. W. W. Richardson, Mercer, Pa.

Dr. William H. Robey, Jr., Boston, read a paper on "Nervous System Sequelae in Three-Day Fever." Discussed by Drs. Charles A. Rosewater, Newark, N. J.; W. H. Mayer, Pittsburgh, and Max H. Weinberg, Pittsburgh.

SECTION ON DERMATOLOGY

WEDNESDAY, JUNE 11—AFTERNOON

The meeting was called to order at 2:20 by the chairman, Dr. Otto H. Foerster, Milwaukee.

Dr. Sigmund Pollitzer, New York, presented the following resolution, which was adopted:

Resolved, That in the opinion of this section the subject of syphilis properly belongs to the Section on Dermatology; and

Resolved, That the House of Delegates be petitioned to amend the title of this section by adding to its present title the words *and Syphilis*.

The chairman appointed the following nominating committee: Drs. Howard Morrow, San Francisco; Harry G. Irvine, Minneapolis, and Richard L. Sutton, Kansas City, Mo.

Dr. Otto H. Foerster, Milwaukee, read the chairman's address entitled "Dermatology and Associated Disorders of the Mucous Membranes."

The following papers were read as a symposium on "Dermatology and Syphilology During the War":

Dr. Warren Walker, Philadelphia: "Dermatology and Syphilology in the Army."

Dr. Henry H. Hazen, Washington, D. C.: "Dermatology and Syphilology in a Medical Advisory Board."

Dr. C. Guy Lane, Woburn, Mass.: "Experiences with Scabies at a Debarkation Port."

Dr. Harry G. Irvine, Minneapolis: "Responsibilities in the Treatment of Syphilis."

These four papers were discussed by Drs. Hugh Young, Baltimore; F. C. Knowles, Philadelphia; William Allen Pusey, Chicago; Rachelle S. Yarros, Chicago; Harold N. Cole, Cleveland; C. C. Pierce, Washington, D. C.; Jay Frank Schamberg, Philadelphia; F. W. Cregor, Indianapolis; W. D. Calvin, Ft. Wayne, Ind.; William H. Guy, Pittsburgh; Henry H. Hazen, Washington, D. C., and Harry G. Irvine, Minneapolis.

THURSDAY, JUNE 12—MORNING

The meeting was called to order at 9:15 by the chairman.

Dr. Harold N. Cole and Sidney Littman, Cleveland, presented a paper entitled "A Clinical Study on the Use of Calomel Inunctions." Discussed by Drs. Jay Frank Schamberg, Philadelphia; Joseph Zeisler, Chicago; Harry G. Irvine, Minneapolis; Richard L. Sutton, Kansas City, Mo.; Henry H. Hazen, Washington, D. C., and Harold N. Cole, Cleveland.

Dr. John E. Lane, New Haven, Conn., read a paper on "Vitiligo and Syphilis: An Examination for the Evidence of Syphilitic Vitiligo." Discussed by Drs. William Allen Pusey, Chicago; Harry G. Irvine, Minneapolis; Jay Frank Schamberg, Philadelphia; Joseph Zeisler, Chicago; Henry R. Varney, Detroit, and John E. Lane, New Haven, Conn.

Drs. Jay Frank Schamberg and Rose Hirschler, Philadelphia, presented a paper entitled "The Treatment of Syphilis." Discussed by Drs. Joseph Zeisler, Chicago; William H. Guy, Pittsburgh; John E. Lane, New Haven, Conn.; Harry G. Irvine, Minneapolis; Henry H. Hazen, Washington, D. C., and Jay Frank Schamberg, Philadelphia.

Dr. William H. Guy, Pittsburgh, read a paper on "Observations on the Treatment of Syphilis." Discussed by Drs. William Allen Pusey, Chicago; Harold N. Cole, Cleveland; Henry E. Michelson, Minneapolis; Fred Wise, New York, and William H. Guy, Pittsburgh.

Dr. Henry E. Michelson, Minneapolis, read a paper on "Syphilitic Epididymitis." No discussion.

Dr. Richard L. Sutton, Kansas City, Mo., read a paper on "Ragweed Dermatitis." Discussed by Drs. C. A. Simpson, Washington, D. C.; J. H. Blaisdell, Boston; Everett S. Lain, Oklahoma City; William Allen Pusey, Chicago; Harold N. Cole, Cleveland; Fred Wise, New York; Jay Frank Schamberg, Philadelphia; H. J. Perry, Boston, and Richard L. Sutton, Kansas City, Mo.

Dr. Henry R. Varney, Detroit, read a paper on "Importance of Normal Amount of Oil in the Skin." Discussed by Drs. Richard L. Sutton, Kansas City, Mo.; Harold N. Cole, Cleveland; William Allen Pusey, Chicago; John E. Lane, New Haven, Conn.; G. A. Hare, Fresno, Calif.; C. A. Simpson, Washington, D. C., and Henry R. Varney, Detroit.

FRIDAY, JUNE 13—AFTERNOON

The meeting was called to order at 2:15 by the chairman.

The following officers were elected: chairman, Dr. Oliver Samuel Ormsby, Chicago; vice chairman, Dr. John E. Lane, New Haven, Conn.; secretary, Dr. Walter J. Highman, New York; delegate, Dr. George M. MacKee, New York, alternate, Dr. William Allen Pusey, Chicago.

Dr. Howard Morrow, San Francisco, read a paper on "Two Years of Radium." Discussed by Drs. William Allen Pusey, Chicago; Everett S. Lain, Oklahoma City; William H. Guy, Pittsburgh, and Howard W. Morrow, San Francisco.

Dr. Fred Wise, New York, read a paper on "Roentgen-Ray Treatment of Widespread and Generalized Skin Diseases." Discussed by Drs. Everett S. Lain, Oklahoma City; George M. MacKee, New York; J. D. Gibson, Denver; Walter J. Highman, New York; Joseph Zeisler, Chicago; Henry H. Hazen, Washington, D. C.; William Allen Pusey, Chicago; R. A. McDonnell, New Haven, Conn., and Fred Wise, New York.

Dr. William L. Clark, Philadelphia, read a paper on "Treatment of Nevus Vasculosis and Other Skin Defects by the Electrodesiccation Method, Ultraviolet Rays, Radium and Electrolysis." Discussed by Dr. Henry H. Hazen, Washington, D. C.; William Allen Pusey, Chicago; Laura A. Lane, Faribault, Minn.; John E. Lane, New Haven, Conn.; J. D. Gibson, Denver, and William L. Clark, Philadelphia.

Dr. J. Frank Wallis, Washington, D. C., read a paper on "The Moulage as a Record Employed at the Army Medical Museum." Discussed by Drs. William Allen Pusey, Chicago; J. D. Gibson, Denver, and J. Frank Wallis, Washington, D. C.

Drs. Udo J. Wile and Lyle Kingery, Ann Arbor, Mich., presented a paper on "The Etiology of Common Warts: An Experimental Study." Discussed by Drs. William T. Corlett, Cleveland; William C. MacCarty, Rochester, Minn.; Harry G. Irvine, Minneapolis; Udo J. Wile, Ann Arbor, Mich., and Lyle Kingery, Ann Arbor, Mich.

Dr. George M. MacKee, New York, read a paper on "Dermatothlasia." Discussed by Drs. Udo J. Wile, Ann Arbor, Mich.; Fred Wise, New York; William Allen Pusey, Chicago; J. D. Gibson, Denver; E. Graham Little, London, England, and George M. MacKee, New York.

SECTION ON PREVENTIVE MEDICINE AND PUBLIC HEALTH

WEDNESDAY, JUNE 11—MORNING

The meeting was called to order at 9 a. m. by the chairman, Dr. C. St. Clair Drake, Springfield, Ill.

Dr. C. St. Clair Drake read as the chairman's address a paper on "The Influence of the War on Preventive Medicine and Public Health," which was referred to the Committee on Resolutions. The paper was discussed by Drs. J. P. Davin, New York, and C. C. Pierce, Washington, D. C.

Dr. Juan Guiteras, Havana, Cuba, read a paper on "Public Health Problems of the Southern Countries." Discussed by Dr. N. T. McLean, U. S. Navy; Mr. L. I. Dublin, New York, and Dr. Juan Guiteras.

Dr. Juan Guiteras, Havana, Cuba; Sir Arthur Newsholme, England, and Capt. René Sand, Brussels, Belgium, were nominated for Honorary Fellowship in the Association.

Dr. William E. Darnall, Atlantic City, N. J., read a paper on "What New Jersey Has Done in Mosquito Extermination." Discussed by Drs. B. Franklin Royer, Philadelphia; Juan Guiteras, Havana, Cuba; Dr. John A. Ferrell, New York; J. D. McLean, Harrisburg, Pa.; John P. Davin, New York; Arthur T. McCormack, Bowling Green, Ky., and William E. Darnall, Atlantic City, N. J.

Dr. Leslie L. Lumsden, Washington, D. C., read a paper on "Recent and Pending Legislation Affecting Public Health Control." Discussed by Drs. Arthur T. McCormack, Bowling Green, Ky., and W. S. Rakin, Raleigh, N. C.

A resolution endorsing a bill pending in Congress providing for physical education, etc., was introduced, approved and referred to the House of Delegates.

Dr. A. T. McCormack, Bowling Green, Ky., moved that a representative of the American Medical Association be appointed as a member of the National Council on Public Health Education. The motion was seconded and carried and referred to the House of Delegates.

Dr. Bertis R. Wakeman, Hornell, N. Y., read a paper on "The Demand for Community Nursing Service in Rural Districts."

The secretary, Dr. D. B. Lowe, Akron, Ohio, presented the proposed By-Laws for the section adopted at the February meeting of the secretaries of the sections. On motion duly seconded and carried the By-Laws were adopted as read.

The paper by Dr. Allen W. Freeman, Columbus, Ohio, on "Ohio's Health Plan" (not read) was discussed by Dr. J. N. Hurty, Indianapolis; Mr. John A. Lapp, director of the Health Insurance Commission of Ohio, and Drs. Hastings, Canada; John P. Davin, N. Y.; C. St. Clair Drake, Springfield, Ill.; Arthur T. McCormack, Bowling Green, Ky.; Otto P. Geier, Cincinnati; J. F. Hogan, Baltimore; Harold B. Wood, Providence, R. I.; L. L. Lumsden, Washington, D. C.

The chair appointed as a nominating committee Drs. Arthur T. McCormack, Bowling Green, Ky.; Guy L. Kiefer, Detroit, and L. L. Lumsden, Washington, D. C.

THURSDAY, JUNE 12—MORNING

The meeting was called to order at 9 o'clock by the chairman.

The following officers were elected: chairman, Dr. James A. Hayne, Columbia, S. C.; vice chairman, Dr. John D. McLean, Harrisburg, Pa.; secretary, Dr. Clarence D. Selby, Toledo, Ohio; delegate, Dr. C. St. Clair Drake, Springfield, Ill.; alternate, Dr. W. S. Rankin, Raleigh, N. C.

Dr. George Thomas Palmer, Springfield, Ill., read a paper on "General Health Activities and Their Influence on Tuberculosis Mortality." Discussed by Drs. L. L. Lumsden, Washington, D. C.; Juan Guiteras, Havana, Cuba; John P. Davin, New York; William C. Woodward, Boston; Arthur T. McCormack, Bowling Green, Ky., and George Thomas Palmer, Springfield, Ill.

A resolution offered by Dr. L. L. Lumsden, Washington, D. C., recommending amendments to the by-laws providing for elimination from membership of those who refuse or fail to report communicable diseases was discussed by Mr. Frederick L. Hoffman, Newark, N. J., and Drs. J. P. Davin, New York; C. St. Clair Drake, Springfield, Ill.; Wilfred H. Kellogg, San Francisco; Dr. S. L. Jepson, Charleston, W. Va.; Dr. L. D. Rawlings, Chicago; J. D. McLean, Harrisburg, Pa.; William C. Woodward, Boston; Oscar Dowling, Shreveport, La.; D. B. Lowe, Akron, Ohio, and L. L. Lumsden, Washington, D. C.

(Not submitted to the House of Delegates.)

Dr. Franklin C. Gram, Buffalo, read a paper on "The Aftermath of Influenza."

Mr. Frederick L. Hoffman, Newark, N. J., read a paper on "Some Practical Statistics of Influenza Morbidity and Mortality."

These two papers were discussed by Drs. A. Leo Franklin, Cumberland, Md.; E. B. Freilich, Chicago; Bertis R. Wakeman, Hornell, N. Y.; Sir Arthur Newsholme, England; Victor C. Vaughan, Ann Arbor, Mich.; Wilfred H. Kellogg, San Francisco; Harold B. Wood, Providence, R. I.; Mr. L. I. Dublin, New York; Dr. Hastings, Toronto, Canada; Franklin C. Gram, Buffalo, and Mr. Frederick L. Hoffman.

Dr. C. C. Pierce, Washington, D. C., read a paper on the "Progress of Venereal Disease Control." Discussed by Dr. Wilfred H. Kellogg, San Francisco; A. E. Chase, Texarkana; Franklin L. Gram, Buffalo; L. D. Rawlings, Chicago, and C. C. Pierce, Washington, D. C.

Dr. H. A. Streator, Boston, presented a resolution calling on Congress to make appropriations for the Public Health Service. Discussed by Dr. J. W. Schereschewsky, Washington, D. C. Amended and adopted.

(Not submitted to the House of Delegates.)

Dr. Leopold Marcus, New York, read a paper on "Open Air Classes in New York City." Discussed by Miss Annie Morrison, Grand Rapids, Mich.

Dr. Josephine B. Neal, New York, read a paper on "Encephalitis Lethargica." Discussed by Dr. J. F. Hogan, Baltimore.

FRIDAY, JUNE 13—AFTERNOON

A joint meeting was held with the Sections on Pharmacology and Therapeutics and Pathology and Physiology.

SECTION ON UROLOGY

WEDNESDAY, JUNE 11—MORNING

The meeting was called to order at 9:20 by the chairman, Dr. W. F. Braasch, Rochester, Minn.

Dr. W. F. Braasch read the chairman's address entitled "Dilatation of the Ureter and Renal Pelvis." Discussed by Drs. Guy L. Hunner, Baltimore; Hugh H. Young, Baltimore; Leo Buerger, New York; A. E. Goldstein, Baltimore; John R. Caulk, St. Louis, and Alfred I. Folsom, Dallas, Texas.

Dr. William J. Mayo Rochester, Minn., read a paper on "Hematogenous Infections of the Kidneys." Discussed by Drs. Hugh H. Young, Baltimore; William Linder, Brooklyn; Guy L. Hunner, Baltimore; Leon Louria, Brooklyn, and Frank Hinman, San Francisco.

Dr. William E. Lower, Cleveland, read a paper on "Ureteral Transplantation in Inoperable Conditions of the Bladder." Discussed by Dr. B. A. Thomas, Philadelphia.

Dr. Albert J. Ochsner, Chicago, read a paper on "Clinical Observations in the Treatment of Nephrolithiasis." Discussed by Drs. Charles M. Harpster, Toledo, Ohio; V. D. Lespinasse, Chicago; A. J. Crowell, Charlotte, N. C., and Guy L. Hunner, Baltimore.

The chairman appointed Drs. William C. Quinby, John R. Caulk and Carl Wheeler as temporary members of the executive committee in the absence of the three regular members.

Dr. John R. Caulk, St. Louis, read a paper on "Urologic Findings in Diseases of the Central Nervous System." No discussion.

Dr. Anton G. Rytina, Baltimore, read a paper on "Relief of Essential Hematuria by Intrapelvic Injections of Silver Nitrate." No discussion.

THURSDAY, JUNE 12—MORNING

Dr. Budd C. Corbus, Chicago, read a paper on "The Civilian Venereal Disease Dispensary as a War Measure."

Dr. Oswald S. Lowsley, New York, read a paper on "Some Problems in Urology in the United States Navy."

Dr. Gideon Timberlake, Baltimore, read a paper on "The Army School of Urology."

Dr. Hugh H. Young, Baltimore, read a paper on "Department of Urology, American Expeditionary Forces."

Dr. Elmer B. Tauber, Cincinnati, read a paper on "The Early Diagnosis and a Comparative Standardization of the Treatment of Syphilis."

These five papers were discussed by Drs. Abraham L. Wolbarst, New York; Irving Simon, Nashville, Tenn.; Harry W. Plaggemeyer, Detroit; V. D. Lespinasse, Chicago; A. G. Rytina, Baltimore; William E. Keane, Detroit; J. R. Dillon, San Francisco; P. A. Jacobs, Cleveland; Elmore B. Tauber, Cincinnati, and Hugh H. Young, Baltimore.

The chairman announced that the election of officers would be held on Friday in the future, instead of on Thursday.

The chairman brought before the section for adoption certain standing rules for the sections which were approved at a conference of the section secretaries.

The resolutions were adopted as read.

The foreign delegates in attendance at this annual session were nominated as Honorary Fellows of the American Medical Association.

Dr. Leo Buerger, New York, read a paper on "Contracture of the Neck of the Bladder: Its Pathology and Operative Treatment." Discussed by Drs. Hugh H. Young, Baltimore; William C. Quinby, Boston; Oswald S. Lowsley, New York; H. G. Bugbee, New York, and Alexander Randall, Philadelphia.

Dr. Alfred I. Folsom, Dallas, Texas, read a paper on "Malakoplakia of the Bladder: Report of Two Cases." Discussed by Dr. Arthur L. Chute, Boston.

FRIDAY, JUNE 13—MORNING

The following officers were elected: chairman, Dr. William E. Lower, Cleveland; vice chairman, Dr. Richard F. O'Neil, Boston; secretary, Dr. E. O. Smith, Cincinnati; delegate, Dr. Edward L. Keyes, Jr., New York; alternate, Dr. H. G. Hamer, Indianapolis.

Dr. Noah E. Aronstam, Detroit, read a paper on "The Frequency and Significance of Granular Urethritis." No Discussion.

Dr. Ernest M. Watson, Buffalo, read a paper on "The Colliculus Seminalis at Birth: With a Report of the Origin, Development and Zonal Distribution of Its Gland Tubules." Discussed by Drs. Anton G. Rytina, Baltimore; Gideon Timberlake, Baltimore, and L. Herman, Philadelphia.

Dr. Harry W. Plaggemeyer, Detroit, read a paper on "Report on Shell Fractures of Spine, Studied at Walter Reed Army General Hospital, with Observations on Changes in Kidney and Bladder Function." Discussed by Drs. Budd C. Corbus, Chicago; Abraham L. Wolbarst, New York; Francis R. Hagner, Washington, D. C.; V. D. Lespinasse, Chicago; Hugh H. Young, Baltimore; William E. Lower, Cleveland; John R. Caulk, St. Louis, and Harry W. Plaggemeyer, Detroit.

Dr. William C. Quinby, Boston, read a paper on "Some Urologic Aspects of Dermoid Cysts." Discussed by Drs. Irving Simon, Nashville, Tenn.; Hugh H. Young, Baltimore, and Arthur L. Chute, Boston.

Dr. Frank Hinman, San Francisco, read a paper on "Etiology of Vesical Diverticulum." Discussed by Drs. V. D. Lespinasse, Chicago; Dr. William E. Lower, Cleveland; Dr. Hugh H. Young, Baltimore; Anton G. Rytina, Baltimore, and Francis R. Hagner, Washington, D. C.

SECTION ON ORTHOPEDIC SURGERY

WEDNESDAY, JUNE 11—MORNING

The section was called to order at 9:20 by the chairman, Dr. Emil S. Geist, Minneapolis.

Dr. Edwin W. Ryerson, Chicago, read a paper on "Intermedullary Beef-Bone Splints in Fractures of Long Bones: New Technic of Application." Discussed by Mr. Ernest W. Hey Groves, England, and Drs. Horace R. Allen, Indianapolis; Robert McE. Schauffler, Kansas City, Mo.; Joseph E. Root, Hartford, Conn.; Fred S. Williams, Bridgeport, Conn., and Edwin E. Ryerson, Chicago.

Dr. James W. Sever, Boston, read a paper on "Osteomyelitis." Discussed by Drs. Henry Ling Taylor, New York; Reginald H. Sayre, New York; Mr. Ernest W. Hey Groves, England; Drs. James T. Watkins, San Francisco; Walter M. Brickner, New York, and James W. Sever, Boston.

Dr. William L. Sneed, New York, read a paper on "Surgical Treatment and After-Care of Old, Unreduced Pott's Fractures." Discussed by Dr. Zabdiel B. Adams, Boston; Mr. Ernest W. Hey Groves, England; Drs. Willis C. Campbell, Memphis, Tenn.; James W. Sever, Boston; Harry E. Stewart, New Haven; Charles M. Jacobs, Chicago; Fred J. Gaenslen, Milwaukee, and William L. Sneed, New York.

The following two papers were read as a symposium on "Amputations":

Dr. Clarence L. Starr, Toronto: "A Consideration of the Problems Presented by Amputations."

Dr. E. J. Rose, Gallipolis, Ohio: "Amputation Stumps in Relation to the Fitting of Artificial Limbs."

These two papers were discussed by Drs. Philip D. Wilson, Columbus, Ohio; Reginald H. Sayre, New York; Jabez N. Jackson, Kansas City, Mo.; Edwin W. Ryerson, Chicago; C. W. Hopkins, Chicago; Clarence L. Starr, Toronto, and E. J. Rose, Gallipolis.

THURSDAY, JUNE 12—MORNING

The meeting was called to order at 9:15 by the chairman.

Dr. William C. Peters, Bangor, Me., read a paper on "The Foot Problem in the Army." Discussed by Drs. Edwin W. Ryerson, Chicago; Roland Hammond, Providence, R. I.; Henry Ling Taylor, New York; C. L. Lowman, Los Angeles; John Ridlon, Chicago, and James T. Rugh, Philadelphia.

Dr. Rudolph S. Reich, Cleveland, read a paper on "Improvised Orthopedic Exercising Apparatus." Discussed by Drs. Zabdiel B. Adams, Boston, and Rudolph S. Reich, Cleveland.

Dr. Russell A. Hibbs, New York, read a paper on "An Operation for Claw Foot." Discussed by Drs. Benjamin P. Farrell, New York; Fred S. Williams, Bridgeport, Conn.; James P. Lord, Omaha; John Ridlon, Chicago; Edwin W. Ryerson, Chicago; James W. Sever, Boston; Samuel W. Boorstein, New York; Russell A. Hibbs, New York; John L. Porter, Chicago, and Ellis W. Jones, Los Angeles.

Dr. Emil S. Geist, Minneapolis, read the chairman's address, entitled, "Some of the Things that Orthopedic Surgery has Done for the War and that the War has Done for Orthopedic Surgery." No discussion.

Dr. James T. Rugh, Philadelphia, read a paper on "Precombat Orthopedic Work in the United States." Discussed by Drs. Harold D. Corbusier, Plainfield, N. J.; Zabdiel B. Adams, Boston; Charles M. Jacobs, Chicago, and James T. Rugh, Philadelphia.

Dr. Leo Meyer, New York, read a paper on "The Orthopedic Surgeon and Industrial Accidents." Discussed by Drs. A. H. Cilley, New York; John Ridlon, Chicago; Samuel W. Boorstein, New York; C. A. Lowman, Los Angeles, and Leo Meyer, New York.

Dr. James C. Graves, Jr., Spokane, Wash., read a paper on "The Curative Work Shop." Discussed by Drs. Zabdiel B. Adams, Boston; Horace R. Allen, Indianapolis; Albert H. Freiberg, Cincinnati; Roland Hammond, Providence, R. I.; H. Winnett Orr, Lincoln, Neb.; A. H. Cilley, New York; John Ridlon, Chicago; Harold D. Corbusier, Plainfield, N. J.; James T. Rugh, Philadelphia; J. D. Griffith, Kansas City, Mo., and James C. Graves, Jr., Spokane, Wash.

FRIDAY, JUNE 13—MORNING

The meeting was convened at 9 o'clock by the chairman

The following officers were elected for the ensuing year: Chairman, Dr. George W. Hawley, Bridgeport, Conn.; vice chairman, Dr. Roland Hammond, Providence, R. I.; secretary, H. B. Thomas, Chicago (continued); delegate, Dr. John Ridlon, Chicago.

Dr. Ridlon reported that at a recent meeting of the House of Delegates a resolution had been presented to the effect that no member of the Association should read a paper before any section on two succeeding years, except at the unanimous request of the section. He stated that this resolution had been tabled, and asked for instructions as to his own action should it be taken from the table.

Dr. Albert H. Freiberg, Cincinnati, moved that it was the sense of the meeting that this was not in accord with the opinion of the members of the Section on Orthopedic Surgery, who believed that this matter should be left to the individual sections for their own decision. The motion was seconded and carried.

Dr. William C. Peters, Bangor, Maine, moved that the section go on record, since very little or no clinical work had been done in the reconstruction hospitals, as recommending that this work be put into the hands of orthopedic surgeons exclusively and controlled completely by them; reconstruction work being understood to include all curative work and occupational therapy. Seconded and carried. The matter was entrusted to Dr. Ridlon to bring before the Association and have it go through the proper channels for reaching the Surgeon-General.

Dr. George W. Hawley, Bridgeport, Conn., read a paper on "Early Functional Results after Secondary Suture, Base Hospital No. 9, France." Discussed by Drs. William W. Plummer, Buffalo; Joel E. Goldthwait, Boston; Reginald H. Sayre, New York; Willis C. Campbell, Memphis, Tenn.; H. W. Orr, Lincoln, Neb.; Joseph Byrne, New York, and George W. Hawley, New York.

Dr. Joel E. Goldthwait, Boston, read a paper on "The Standardized Splints and Methods of Treatment in Bone and Joint Injury, A. E. F." Discussed by Drs. William W. Plummer, Buffalo; J. A. Blake, New York; Kellogg Speed, Chicago; Leo Meyer, New York; Samuel C. Baldwin, Salt Lake City; Reginald H. Sayre, New York; H. R. Allen, Indianapolis; H. W. Orr, Lincoln, Neb., and Joel E. Goldthwait, Boston.

Dr. Willis C. Campbell, Memphis, Tenn., read a paper on "Fracture of the Neck of the Femur; and Analysis of One Hundred and Sixteen Cases."

Dr. Melvin S. Henderson, Rochester, Minn., read a paper on "Ununited Fractures of the Hip."

These two papers were discussed by Drs. Ellis W. Jones, Los Angeles; Wallace Blanchard, Chicago; Hugh McKenna, Chicago; John Ridlon, Chicago; Z. B. Adams, Boston; H. L. Taylor, New York; Charles E. Thompson, Scranton; James W. Sever, Boston; Fred J. Gaenslen, Milwaukee; Edwin W. Ryerson, Chicago; Willis C. Campbell, Memphis, Tenn., and Melvin S. Henderson, Rochester, Minn.

The following three papers were read as a "Symposium on Nerve Surgery":

Dr. Karl W. Ney, New Orleans: "Indications for Surgical Intervention in Peripheral Nerve Injuries."

Dr. Charles A. Elsberg, New York: "Operative Treatment of Peripheral Nerve Injuries."

Dr. Murray S. Danforth, Providence, R. I.: "Postoperative Treatment of Peripheral Nerve Injuries."

These three papers were discussed by Drs. Frederick C. Kidner, Detroit; Samuel W. Boorstein, New York; Dean D. Lewis, Chicago; M. B. Tinker, Ithaca, N. Y.; Tom A. Williams, Washington, D. C.; W. W. Babcock, Philadelphia, and Karl W. Ney, New Orleans.

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

Wednesday, June 11—Morning

The meeting was called to order by the chairman, Dr. William M. Beach, Pittsburgh.

Dr. Beach read the chairman's address, entitled "Spirit of the Physician in War and Peace." No discussion.

Dr. Dwight H. Murray, Syracuse, N. Y., read a paper on "Constipation: A New Definition, the Primary Causes and Its Hygienic Treatment." Discussed by Drs. J. M. Frick, Toledo, Ohio; Louis Lefrak, New York; J. Coles Brick, Philadelphia; E. H. Terrell, Richmond, Va.; Mary Ella Dunning Rose, New York; Frank C. Yeomans, New York; Robert Hugh Rose, New York; J. Rawson Pennington, Chicago; R. W. Jackson, Fall River, Mass., and Nathan Rosewater, Cleveland.

Dr. Louis J. Hirschman, Detroit, read a paper on "Proctology in a War Hospital." Discussed by Drs. Alois B. Graham, Indianapolis; D. C. McKenney, Buffalo; John L. Jelks, Memphis, Tenn.; Dwight H. Murray, Syracuse, N. Y.; J. Coles Brick, Philadelphia; J. D. Reeder, Baltimore, and Aimé Chartier, Sorel, Quebec.

Dr. Charles J. Drueck, Chicago, read a paper on "Late Syphilis Within the Rectum."

Dr. Frank C. Yeomans, New York, read a paper on "Stricture of the Rectum."

These two papers were discussed by Drs. John L. Jelks, Memphis, Tenn.; Holland H. Donaldson, Pittsburgh; J. Rawson Pennington, Chicago; J. Coles Brick, Philadelphia; Dwight H. Murray, Syracuse, N. Y., and E. G. Martin, Detroit.

Dr. J. Rawson Pennington, Chicago, read a paper on "Examination of the Patient." Discussed by Drs. Frank C. Yeomans, New York; John L. Jelks, Memphis, Tenn., and E. G. Martin, Detroit.

Thursday, June 12—Morning

Dr. Anthony Bassler, New York, read a paper on "Gastric Cell Primary Atrophy."

Drs. Julius Friedenwald and Theodore H. Morrison, Baltimore, presented a paper on "Further Observations on the Gastro-Intestinal Disturbances Encountered in Pernicious Anemia."

These two papers were discussed by Drs. Max Einhorn, New York; Louis Lefrak, New York; Arthur F. Chace, New York; Martin E. Rehfuss, Philadelphia; J. A. Lichty, Pittsburgh, and G. A. Friedman, New York.

Dr. Walter C. Alvarez, San Francisco, read a paper on "The Metabolic Gradient Underlying Peristalsis." Discussed by Drs. Jacob Gutman, New York; Franklin W. White, Boston; James T. Case, Battle Creek, Mich., and Nathan Rosewater, Cleveland.

Dr. Thomas R. Brown, Baltimore, read a paper on "The Late Results of Supposedly Successful Operations on the Digestive Tract." Discussed by Drs. John A. Lichty, Pittsburgh; Alfred A. Strauss, Chicago; Julius Friedenwald, Baltimore; Robert Hugh Rose, New York; Harris Weinstein, New York; G. A. Friedman, New York; Henry Illoway, New York, and Byron C. Darling, New York.

Dr. Dudley Roberts, New York, read a paper on "Certain Limitations of Roentgen-Ray Diagnosis of Gastro-Intestinal Diseases."

Dr. Russell D. Carman, Rochester, Minn., read a paper on "The Operability of Cancer of the Stomach as Determined by the Roentgen Ray."

These two papers were discussed by Drs. Anthony Bassler, New York; Byron C. Darling, New York; Louis J. Hirschman, Detroit; George E. Pfahler, Philadelphia; James T. Case, Battle Creek, Mich.; R. Walter Mills, St. Louis; L. Gregory Cole, New York, and Thomas R. Brown, Baltimore.

Friday, June 13—Morning

The following officers were elected: chairman, Dr. Frank Smithies, Chicago; vice chairman, Dr. Louis J. Hirschman, Detroit; secretary, Dr. Horace W. Soper, St. Louis; delegate, Dr. Alois B. Graham, Indianapolis.

Dr. Max Einhorn, New York, read a paper on "Further Experiences with the String Test." Discussed by Drs. Sidney K. Simon, New Orleans; Clement R. Jones, Pittsburgh; Israel O. Palefski, New York; Julius Friedenwald, Baltimore; William Van V. Hayes, New York, and L. Gregory Cole, New York.

Dr. Sidney K. Simon, New Orleans, read a paper on "The Importance of Detecting Protozoal Cysts in the Feces."

Dr. John L. Jelks, Memphis, Tenn., read a paper on "The Prevalence of Ameba, Cercomonas Intestinalis-Hominis, and Pellagrous Infection in the South, the Responsibility for which Rests on Nation and State: Suggestions as to Means of Control."

These two papers were discussed by Drs. James C. Johnson, Atlanta, Ga.; E. J. Wood, Wilmington, N. C.; Anthony Bassler, New York; Ernest Zueblin, Cincinnati; J. Rawson Pennington, Chicago; William Allan, Charlotte, N. C.; J. M. Bell, St. Joseph, Mo., and Frank C. Yeomans, New York.

Dr. Seale Harris, Birmingham, Ala., read a paper on "Progress in Gastro-Enterology During the World War." Discussed by Drs. William M. Beach, Pittsburgh, and A. E. Austin, Boston.

Dr. Clement R. Jones, Pittsburgh, read a paper on "Influence of Endocrine Functioning on Gastro-Intestinal Conditions." Discussed by Drs. G. A. Friedman, New York; J. P. Sawyer, Cleveland; Solomon Solis Cohen, Philadelphia; Nathan Rosewater, Cleveland; Ernest Zueblin, Cincinnati, and H. S. Plummer, Rochester, Minn.

Drs. George David Stewart and William Howard Barber, New York, presented a paper entitled "The Gastric Hypermotility Associated with Diseases of the Gallbladder, Duodenum and Appendix: A Clinical and Experimental Study." Discussed by Drs. Anthony Bassler, New York; R. Walter Mills, St. Louis; Israel O. Palefski, New York; William Van V. Hayes, New York, and G. A. Friedman, New York.

SECTION ON MISCELLANEOUS TOPICS

WEDNESDAY, JUNE 11—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Harry E. Mock, Chicago.

Dr. Mock read the chairman's address, entitled "A Talk Concerning the Development of Human Resources."

Dr. William I. Clarke, Jr., Worcester, Mass., read a paper on "Preventive Surgery as Demonstrated by Industrial Practice." Discussed by Drs. William S. O'N. Sherman, Pittsburgh; Otto P. Geier, Cincinnati, and Joseph W. Schereschewsky, Washington, D. C.

Dr. C. E. Ford, New York, read a paper on "Industrial Medical Practice and Sickness Prevention as a Factor in Public Health." Discussed by Drs. William A. Sawyer, Philadelphia; David L. Edsall, Boston; Charles J. Hastings, Toronto; Otto P. Geier, Cincinnati; S. Dana Hubbard, New York; Augustus Wadsworth, Albany, N. Y., and Guy L. Kiefer, Detroit.

The following papers were read as a symposium on the "Scope of Industrial Medicine and Surgery:

Dr. Joseph W. Schereschewsky, Washington, D. C.: "The Enlarged Program of the United States Public Health Service, Division of Industrial Hygiene and Medicine."

George A Soper, Sanitary Corps, U. S. Army: "The Efficacy of Measures for the Prevention of Disease."

These papers were discussed by Colonel Kramer, Department on Sanitation, U. S. Army, and Drs. A. E. Chase, Texarkana; A. E. Norton, Philadelphia; Charles J. Hastings, Toronto; H. H. Koons, Los Angeles; W. V. Smith, Alameda, Calif.; Clarence D. Selby, Toledo, Ohio, and Eli Harris, New York.

FRIDAY, JUNE 13—AFTERNOON

The meeting was called to order at 2 p. m. by the chairman.

Dr. Frank Billings, Chicago, read a paper on "Lessons from Rehabilitation of Disabled Soldiers, and Their Application to the Industrial Army." Discussed by Dr. James Bordley, Jr., Baltimore.

Dr. William Alfred Sawyer presented the following resolution, which was seconded and unanimously adopted:

> WHEREAS, The recent influenza epidemic caused approximately 500,000 deaths in the United States; and
>
> WHEREAS, A large proportion of these deaths were produced by pneumonia and other complications; and
>
> WHEREAS, Influenza, pneumonia and allied diseases now cause approximately one tenth of all the deaths in the United States; and
>
> WHEREAS, Medical science is not yet in possession of complete data as to the cause, modes of transmission, prevention and cure of this disease and its complications, and
>
> WHEREAS, The possession of this knowledge is of grave social and economic concern to the nation; therefore be it
>
> *Resolved,* That it is the sense of those in attendance on the Sections on Pharmacology and Therapeutics, Physiology and Pathology, Preventive Medicine and Public Health here assembled to discuss influenza, that Congress should and is hereby urged to appropriate not less than $1,500,000 to be used under the direction of the U. S. Public Health Service for the investigation of the causes, modes of transmission, prevention and cure of influenza, pneumonia and allied diseases, this sum to be made available to July 1, 1922. (Not submitted to the House of Delegates.)

Mr. R. M. Little, New York, read a paper on "Better Industrial Relations and the Physician's Contribution."

Dr. Otto P. Geier, Cincinnati, read a paper on "Modernizing Our Medical Colleges by Adding Departments of Industrial Medicine and Public Health." Discussed by Drs. David L. Edsall, Boston; Tom A. Williams, Washington, D. C.; Eugene Lyman Fiske, New York; C. P. McCord, Cincinnati; Victor C. Vaughan, Ann Arbor, Mich.; Frank Billings, Chicago, and Gershom H. Hill, Des Moines.

Dr. Clarence D. Selby, Toledo, Ohio, read a paper on "Medical Service for the Small Industrial Units."

Dr. René Sand, Brussels, Belgium, read a paper on "The Industrial Rehabilitation of Belgium." Discussed by Drs. Victor C. Vaughan, Ann Arbor, Mich.; Otto P. Geier, Cincinnati; S. Adolphus Knopf, New York; Frank Billings, Chicago, and Andrew Macfarlane, Albany, N. Y.

REGISTRATION AT ATLANTIC CITY

The total registration at the Victory Meeting—the Atlantic City Session—was 4,929. Below are given two summaries, one by sections and one by states:

REGISTRATION BY SECTIONS

Practice of Medicine	1,486
Surgery, General and Abdominal	1,046
Obstetrics, Gynecology and Abdominal Surgery	309
Ophthalmology	425
Laryngology, Otology and Rhinology	327
Diseases of Children	217
Pharmacology and Therapeutics	45
Pathology and Physiology	66
Stomatology	41
Nervous and Mental Diseases	175
Dermatology	86
Preventive Medicine and Public Health	216
Urology	133
Orthopedic Surgery	113
Gastro-Enterology and Proctology	124
Registrations, not marking any one section	120
Total	4,929

REGISTRATION BY STATES

State	Number	State	Number
Alabama	24	New Jersey	363
Arizona	9	New Mexico	4

THE MEASUREMENT OF FATIGUE IN DISEASE

Fatigue, that is, an unusual degree of susceptibility to fatigue, is a marked characteristic of a number of conditions of impaired vigor and usefulness that have become unexpectedly prominent during the war. Thus, in persons classed as subjects of neurocirculatory asthenia or the so-called effort syndrome and of "irritable heart," fatigue seems to be a conspicuous feature. The fatigue symptoms may be accentuated by even slight attempts at muscular activity. Sometimes it appears to be more marked in persons who may be described as emotionally sensitive. Fatigue plays a significant rôle in the efficiency of the human machine; so that its physiologic manifestations have become the subject of extensive investigation in relation to industrial conditions.[1]

Where psychic factors of sensation and personal impressions are involved it is manifestly difficult to secure data possessing the degree of accuracy that pulse rate, temperature, body weight, heat output, and other metabolic determinations afford. This explains why fatigue cannot be evaluated with the degree of quantitative accuracy that is possible with regard to many other bodily functions. Nevertheless, nothing short of some degree of scientific precision will enable the problems of fatigue to be studied with the same assurance of the validity of the conclusions reached as that which is expected elsewhere in physiologic medical research.

Among the more objective tests of fatigue that have been proposed, the vascular skin reaction long ago described by French physiologists as a white vasomotor reflex and recently introduced for this purpose by Ryan[2] has gained some clinical prominence. The test consists in making, with a suitable blunt instrument, a stroke on the skin of the forearm and noting by means of a stop-watch the time that elapses between the moment of the stimulation and the moment at which the white streak thus caused begins to fade. This time is shorter in the fatigued person.

Applied to persons suffering from an irritable heart, the Ryan skin test has shown itself in the hands of Lieutenant King[3] of the Army Medical Service to be of value in clinical medicine as well as in the industries. He finds that the day curve of fatigue estimations is much the same in the several groups of cases that have the syndrome of irritable heart as in those with organic heart disease. Patients with irritable heart who fall into the groups of general constitutional inferiority or pure physical inferiority show very rapid fatigue on exercise.

A comparison of strength tests, expressing the muscular efficiency of the patients, with their skin vasomotor reflexes indicates that there is a correspondence between the strength of the arteriolar musculature and the strength of the skeletal musculature in a given individual. The trend of King's studies is to indicate further that the readiness of fatigue following exertion is dependent on an actual physical phenomenon and is not merely of psychic origin. In other words, it is by no means justified to say that "fatigue is a habit" with those who are subject to the irritable heart. They do not merely imagine their fatigue; it has, to quote King, apparently a physical basis.

URANIUM AS AN INDUSTRIAL POISON

Certain toxicologic effects of salts of uranium have long been recognized and applied in the study of experimental physiology and pathology. Recently industrial conditions have arisen which may place this element in the class of possible dangers of occupation. Karsner and his collaborators[4] of the Western Reserve University School of Medicine, Cleveland, have asserted that in certain industries uranium is employed or appears as a by-product, and that with the war time scarcity of some other heavy metals, such as tungsten, uranium may be utilized as a partial substitute. In the production of radium, uranium oxid is produced in large quantities, and if uranium were employed in the steel industry the high temperatures used would lead to the formation of one or several oxids, the most important being uranium dioxid and uranous uranate, both of which are insoluble in water. In grinding, polishing, and perhaps in other operations, these oxids might appear in the form of a dust.

Animal experiments conducted by the Cleveland pathologists demonstrate that uranium oxid, the state in which the metal is most likely to reach the upper respiratory tract when distributed industrially in the form of dust, can be toxic and fatal when administered by mouth. This oxid is insoluble in water; but it will dissolve in gastric juice, so that the possibility of the formation of a soluble toxic salt is established. The production of nephritis by uranium salts has long been recognized as an experimental fact, and the method has served to facilitate the study of the pathology of renal functions. Karsner and his associates have observed that the excretion of uranium, so far as it is accomplished, is primarily by way of the kidneys. When functional and anatomic lesions arise in the kidneys through the presence of the poison, the decreased effectiveness of excretion makes matters worse by favoring an accumulation of the metal in the kidney. There is, probably, no special "affinity" of uranium for the kidney cells nor any unusual susceptibility to the poison on their part. The possibility of protecting the kidneys by the administration of alkalis to combat the concomitant acidosis in such cases represents one of the therapeutic considerations that experimental medicine has taught.[5]

P., and Brooks, S. C.: Studies of Uranium Poisoning, II, The Solubility of Uranium Oxide in Artificial and Human Gastric Juice, ibid. **39**: 163, 169, 177 (Nov.) 1918.

Incidentally it should be stated that uranium nitrate was admitted to the Ninth (the most recent) Revision of the U. S. Pharmacopeia. Surely the danger of this salt could not have been appreciated when this action was taken by the Revision Committee. There does not appear to be sufficient evidence of its therapeutic value to warrant inclusion in this official book. The drug is not included in Useful Drugs, prepared by the Council on Pharmacy and Chemistry. The Epitome of the U. S. Pharmacopeia, prepared for the use of physicians by a special committee of the Council on Pharmacy and Chemistry, has this to say under "Actions and Uses": "[Uranium nitrate] . . . has been used, without adequate justification, in the treatment of diabetes and cancer. Solutions are poisonous and produce glucosuria when injected subcutaneously, even in small doses." Our previous knowledge of this drug, now adequately supported by the work of Karsner, should lead the next Revision Committee to omit the drug from the Pharmacopeia.

SIGNIFICANT OBSERVATIONS ON MENINGOCOCCIC MENINGITIS

Fresh outbreaks of epidemic disease in unusual localities or at unexpected periods almost always serve to extend our knowledge of the subject by directing attention to novel aspects which are liable to be overlooked in the regular routine of experience. Contact with the unanticipated is not infrequently a potent stimulus to thought and an incentive for investigation. An unexpected outbreak of typhoid fever among troops that have been subjected to antityphoid vaccination, as has been observed in our army,[6] directs immediate attention to the limitations of this prophylactic measure and emphasizes that it must by no means be regarded as a substitute for the observance of sanitary precautions.[7] The appearance of influenza with unique manifestations serves to make clinicians skeptical as to alleged etiologic factors and causes them to bend their energies anew in the direction of discovering new or unsuspected infective agents. Variable phenomena in the incidence of pneumonia awaken an interest in the study of differential diagnosis.

Thus, epidemiologic phenomena have frequently pointed the way both to a better management of disease and to a clearer understanding of what is involved in it. A new instance is afforded by Olitsky's observations in an epidemic of meningococcic meningitis in a district of South China.[8] An epidemic of this sort among Southern Chinese has been practically unknown heretofore. A mortality of 85 per cent. among unsuitably treated patients bears renewed testimony of the appalling seriousness of the malady. The mechanism of disseminating the meningococcus, as outlined by Flexner,[9] consists in the ejection of the nasopharyngeal secretions into the surrounding atmosphere. The micro-organism is sensitive to an unsuitable environment and readily succumbs outside the body. Hence exceptionally favorable conditions for its immediate transference from person to person are necessary to promote infection. The favorable conditions, in this instance, were brought about by overcrowding during extremely cold weather, along with an outbreak of nasopharyngeal affections. In the area involved, 300,000 Chinese lived in a section about three miles long and one-half mile wide. Furthermore, the occurrence of a pathogenic type of the meningococcus seems to be essential. Hence we can understand why not a single case of the meningitis developed in a jail within the epidemic area. In a series of cases in prisoners living under hygienic conditions and examined by Olitsky, one quarter were found to be carriers. Of these, 50 per cent. yielded irregular or inagglutinable types; 34.3 per cent. the normal type, and only one person the para type.

Olitsky's observations further show that drainage of the spinal fluid, on which reliance was placed at one time, is still a far from satisfactory therapeutic procedure, although it apparently produced some decrease in the death rate. Moreover, the use of a curative serum of poor quality and low in agglutinin content was therapeutically ineffective. The finding of meningococci in the blood, although the observations were made postmortem, taken in connection with similar reports in the literature of the disease, suggests the possible desirability of combining intravenous with the customary intraspinal therapy. From the preventive standpoint the importance of detection and treatment of contact carriers, including the isolation of the "dangerous" carrier, as Olitsky designates the person who harbors numerous meningococci, particularly of the same type as the patients, was especially emphasized. Above all, the prevention of overcrowding is the prominent lesson to be derived from this work in the Far East.

UNDERFEEDING AND GROWTH

Inadequate growth may be attributable to one or more of a number of conditions which deserve to be differentiated. The failure to increase in weight according to the normal expectation may result from underfeeding, from inappropriate food, or from pathologic defects either inherited or acquired. Inborn errors of growth form a special category which falls outside of the sphere of nutrition. The ingestion of food defective in quality rather than quantity may lead to deficiency disorders which may be more or less remediable by appropriate dietary measures. Infantile scurvy serves as an illustration.

The suppression or retardation of growth due to underfeeding per se until comparatively recently has been looked on as fraught with possible undesirable consequences for the victims of it. In experiments on animals, Osborne and Mendel[1] have shown that the capacity to grow in such instances of underfeeding is not entirely lost but is held in reserve until it is exercised. According to their observations, even when the period of stunting through underfeeding is prolonged beyond the time when growth usually ceases, the institution of proper diet will result in prompt resumption of growth and apparent completion of its usual cycle. After such retardations, the renewal of growth is attended with striking accelerations of the developmental processes. This phenomenon of unusually rapid growth following periods of growth suppression has also been studied in children.[2]

These facts regarding the body as a whole have been amplified by more recent findings in respect to the individual organs of the body. It is known that while some organs during inanition tend to maintain approximately their normal relative weight, and others continue to grow, still others undergo losses. The organs affected and the extent of the changes involved vary according to the age of the individual and the length and character of the inanition. Jackson and Stewart and others[3] at the University of Minnesota have noted the mode of recuperation of animals after realimentation. It was found that not all of the organs attain a normal weight in the same order or time; but, in general, it may be said that adequate size of all the more important structures is attained despite the earlier stunting. Whether overcompensatory growth occurs in some cases is not yet clear. For the clinic of childhood the significant indication by analogy is the probable recovery in the various organs after periods of undernutrition. The fortunate prospect of a return to normal in such cases furnishes a powerful incentive toward instituting appropriate dietary treatment wherever growth lags behind the conventional standards because of presumable underfeeding. Retarded growth therefore does not necessarily mean that the hope of attaining a perfect adult form and function is lost; on the contrary, when organic disease is absent there is every reason to encourage the proper restitution through diet. Such is the basis of the efforts devoted to the success of modern clinics for undernourished children.

Current Comment

IODIN AND THE THYROIDS

Iodin and its compounds have been employed for nearly a century in the treatment of disorders associated with the thyroid glands. When Baumann of Freiburg, in 1895, discovered that the thyroid glands contain iodin, there was immediate speculation as to the relation of this chemical element, not found elsewhere in the body in equally appreciable amounts, to the glandular function. The earliest assumption was that the "active principle" of the thyroids contains iodin. Some thyroids contain almost none of the element; but it has been noted that such glands used therapeutically do not seem to manifest the same physiologic activity that is exhibited by thyroid preparations containing iodin. In other words, the potency to produce certain physiologic effects after administration of thyroid has seemed to several investigators to depend on or parallel the iodin content. The active product isolated from the thyroid by Kendall of the Mayo Clinic is rich in iodin.[1] Gudernatsch has recorded the remarkable observation that the feeding of thyroid extract to tadpoles brings about rapid and marked metamorphoses in these animals. Swingle[2] has followed this with the further demonstration that iodin and its compounds fed to the larvae of the frog and the toad stimulate metamorphosis in these animals very rapidly; that is, the results resemble those induced by the hyperthyroidism already described. It has been assumed that all such effects are brought about by the intermediation of the thyroid glands in the animals fed. Allen[3] has shown that thyroidectomized larvae fail to undergo metamorphosis, but instead permanently retain their larval characters. But Swingle has since found that when inorganic iodin is fed to thyroidless larvae of toads, a metamorphosis occurs in an abnormally short time, despite the complete absence of the thyroid gland in them. He therefore concludes that if animals without the vestige of a thyroid gland are stimulated to complete metamorphosis in an abnormally short time by iodin, it would appear that iodin functions within the organism as a hormone itself, and that the gland functions chiefly for storage purposes. The evidence from the thyroidectomized larvae indicates, Swingle adds, that the animal body is capable of utilizing iodin directly without the intermediation of the gland. It is admittedly little more than speculation to transfer the observations on the development of these lowly forms to the problems of thyroid function in man. They are not entirely incompatible with the view that, so far as iodin is concerned, the chief function of the thyroid is one of storage. However, it seems more than likely at present that the unique organic combinations of the element obtainable from the gland are far more potent in their effect on metabolism than are the simple salts of iodin. Whether, therefore, iodin functions best through the intermediation of the glands whereby its potency is augmented remains to be considered.

TRANSITORY ALBUMINURIA

Albuminuria is a symptom that is by no means necessarily indicative of a permanent defect of the renal function. Ordinarily the proteins of the blood do not obtain entrance into the tubules of the kidneys; but it happens occasionally that albumin is found in the urine of persons in whom there is no occasion to suspect the existence of an acute nephritis. This is particularly true after strenuous exercise. Athletes and others performing severe muscular exercise not infrequently give evidence of a temporary albuminuria. Again, there are persons who excrete protein whenever and only when they assume an upright position. This phenomenon, long known under the designation of orthostatic or postural albuminuria, commonly disappears after a time, and in any event must be clearly differentiated from what is observed in true nephritis. There has been considerable speculation from time to time as to the cause of the transitory or "physiologic" types of albuminuria. For the postural forms there is reason to assume that they are the outcome of circulatory changes in the kidneys. Thus the vasomotor reactions and tonus of some persons on standing in an upright position are not as effective as in the average individual, so that venous congestion may occur to some extent in the abdominal viscera. Excretion of protein follows as a consequence; and it disappears as soon as normal circulatory conditions are reestablished. In the case of strenuous muscular exercise, such an explanation is not adequate. There is greater probability of a tendency toward an anemia than a congestion of the renal structures; yet albumin may appear. Bornstein and Lippmann[1] point out that products of vigorous metabolism bring an added factor to bear in this type of transitory albuminurias. In observations on persons engaged in heavy marching, as well as on swimmers, they noted a striking parallelism between the excretion of albumin and the acidity of the urine. The frequency of occurrence of cylindroids also seemed to be related in a similar manner to the concentration of urinary acid. Furthermore, both phenomena of severe exertion—albuminuria and cylindroid formation—were checked by the administration of alkali during the working period. This is not the first time that acidity and albuminuria have been brought into causal relationship in discussions of abnormal kidney function. We shall not discuss the debated question at this time. The preceding comments are intended primarily to point out that so-called physiologic or transitory albuminurias may arise under conditions in which the circulatory manifestations are quite unlike. Nevertheless they may still be outside the realm of the definitely pathologic.

AN EYE TO BUSINESS

A Chicago physician recently received a circular letter from Arntzen, Inc., of the same city. The letter advises that the directors of the corporation have "decided to invite a few more physicians to become stockholders in the Arntzen Corporation." It alleges that this company has "now about one hundred Doctors with us in our work who are thoroughly satisfied with The Arntzen Way." The names of the one hundred are not given. Every physician solicited "will be limited to ten shares or $100." The benefits to be derived (by the physician) from this investment are—still relying on the letter—a "very handsome dividend," to say nothing of the fact that the stock may be used by the physician at its face value to apply on goods purchased from Arntzen, Inc., for his own family or for that of any friend. "This stock," continues the letter, "is to be sold to the Physicians without the knowledge of anyone. This is your business and ours. Every transaction will be absolutely of a confidential nature." The nub of the proposition seems to be the fact that on each bill of goods purchased "in any way through the holder of said certificate of stock, there will be a Ten Per Cent. discount given to the holder of ten shares or $100 of stock." Arntzen, Inc., it should be said, are undertakers; their slogan: "Funerals to Suit Any Purse."

"THE GROUND GLASS OBSESSION"

Obsessions of hidden danger from ground glass in food are likely to spring up in the future as has happened occasionally in the past. It may be worth while to revert again to the subject[1] by calling attention to some analyses of products that were alleged to contain ground glass. In thirty-one out of forty instances of food and glass phobia, analysts investigated the accused products rather than rumors. Ground or powdered glass chiefly had been suspected. The Connecticut Agricultural Experiment Station[2] at New Haven found no evidence of glass in the samples submitted. Silica (or sand), which is widely distributed in foods of

vegetable origin, and crystallized sugar were the substances chiefly responsible for the alarm in these cases. In three instances, one of which was evidently a case of sabotage, glass was detected. Here no analysis was necessary as the large fragments represented a proportion of 2½ ounces per pound of the canned beef under suspicion. In some instances the occasion for the false assumption of the presence of glass is easily traced. The ash of any vegetable matter contains substances which are like glass in kind and quality and are familiar as silica or sand. Moreover, particles of siliceous material in vegetable ashes often show sharp and jagged edges when viewed under the microscope. Fortunately ground glass is scarcely more injurious than are other coarse particles which are frequently swallowed with impunity. This was well realized by Dr. Thomas Brown[3] in the seventeenth century, from whose writings Bailey[2] has extracted the following interesting comment:

> That ground glass is poyson according unto common conceit I know not how to grant. Not only from the innocency of its ingredients, that is, fine sand, and the ashes of glasswort of fearn, which, in themselves are harmless and useful; or because, I find it by many commended for the stone; but also from experience, as having given unto dogs above a dram thereof, subtilly powdered in butter or paste, without any visible disturbance.

Medical Mobilization and the War

Personnel of the Medical Department

For the week ending June 20, there were 13,465 officers in the Medical Corps, a decrease of 466 from the previous week. The Medical Reserve Corps contained 2,494 officers. The total number of physicians discharged since the beginning of the war is 18,699. The records of the discharge branch of the general staff show the following discharges of officers of the Medical Department from Nov. 15, 1918, to noon, June 19, 1919: 1 brigadier-general, 53 colonels, 385 lieutenant-colonels, 1,892 majors, 7,719 captains, 9,714 lieutenants, making a total of 19,764 officers discharged to date. Nov. 15, 1918, there were 30,591 medical officers on duty; June 19, 1919, there were 10,827 officers on duty in the Medical Corps.

Personal News of the Services

William B. Banister, Col., M. C., U. S. Army, department surgeon, Central Department, Chicago, has been notified that the French government will soon confer on him its decoration of Legion of Honor. Colonel Banister, while in France, was commanding officer of the hospital center at Limoges, which included Base Hospital No. 13, the Presbyterian and Cook County Hospital Unit, Chicago, and Hospitals No. 24 and No. 28, of Kansas City, Mo., and also was commanding officer of Convalescent Unit No. 5, which cared for more than 23,000 patients.——Major M. August W. Shockley, Col., M. C., U. S. Army, has returned, after seventeen months' service overseas, to resume his work as head of the medical department of the Army Service School, Fort Leavenworth, Kan.——Robert M. Culler, Col., M. C., U. S. Army, recently returned from France, has been appointed to command the Army and Navy General Hospital, Hot Springs, Ark., succeeding Charles M. Gandy, Col., M. C., U. S. Army, who has been made department surgeon of the Eastern Department.——Homer Folks, New York City, director of the department of civil affairs of the Red Cross in France, formerly secretary of the New York State Charities Aid Association, who has been abroad since July, 1917, has returned home.——Henry I. Raymond, Col., M. C., U. S. Army, department surgeon headquarters, Central Department, was retired from active service, May 24, after more than thirty-seven years' continuous military duty.——Allen D. Lazenby, Capt., M. C., U. S. Army, was retired from active service, June 3, after disability incident to service.——Howard H. Johnson, Col., M. C., U. S. Army, who has been on duty at Newport News, Va., has been ordered to command Army General Hospital No. 21, Denver.——Arthur W. Dunbar, Capt., M. C., U. S. Navy, has recently been placed in command of the Hospital Ship *Mercy*.——John O. Skinner, Major, M. C., U. S. Army, retired, who resigned as superintendent of the Columbia Hospital, Washington, D. C., who returned to active duty during the war, has accepted the position of superintendent of the Emergency Hospital, Washington, D. C.——Merritte W. Ireland, Major-General, M. C., U. S. Army, was given the degree of doctor of laws, by Jefferson Medical College at the commencement exercises.——At the meeting for organization of the Air Service Association, June 13, in Atlantic City, N. J., Dr. John O. McReynolds, Dallas, Texas, was elected president.——Surg.-Gen. Merritte W. Ireland, U. S. Army, was advised, June 10, that the British government has conferred on him the cross of the Companion of the Bath as chief surgeon of the American Expeditionary Forces and later as Surgeon-General of the Army.——Robert E. Noble, Major-General, M. C., U. S. Army, who, it was rumored, had been sent into Belgium as section surgeon of the new service of supplies section organized there, has not been assigned to this duty but is still stationed at Brest, France.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

DISTRICT OF COLUMBIA

New Society Officers.—At the annual meeting of the George Washington University Medical Society, Dr. William J. Mallory was elected president; Dr. Daniel Le Ray Borden, vice president; Dr. Frank A. Hornaday, secretary, and Dr. Elijah W. Titus, treasurer.

Incorporates New Medical Society.—The incorporation of the Medical Society of the District of Columbia is provided for in a bill introduced by Congressman Lazaro of Louisiana, which empowers the society to own and convey real estate. It authorizes the following physicians to corporate themselves as a body corporate: George W. Cook, William G. Morgan, John B. Nichols, William P. Carr, Edward Y. Davidson, Philip S. Roy, Albert L. Stavely, Henry C. Macatee, Edward G. Siebert, J. Russell Verbrycke, Jr., Archie W. Boswell, Charles S. White, James A. Gannon, Hanson T. A. Lemon, Daniel S. Lamb and Virgil B. Jackson.

ILLINOIS

Graduate Lecture.—The fourth lecture of the Graduate Summer Course in Medical Science, in the University of Illinois, College of Medicine, Chicago, was delivered, June 25, by W. E. Burge, Ph.D., associate professor of physiology in the University of Illinois, Urbana, on "Catalase."

Alumni Meeting.—The annual meeting and dinner of the Alumni of the College of Medicine of the University of Illinois was held at Chicago, June 14, and the following officers were elected: president, Dr. Karl A. Meyer, '08; vice presidents, Drs. John W. Birk, '01, and Alexander W.

Burke, '09; secretary, Dr. John C. M. Krasa, '13; treasurer, Dr. Jay L. Armstrong, '04; member of the executive committee, Dr. Emory R. Hayhurst, '08, Columbus, Ohio, and alumni councilor, Dr. Robert W. Morris, '02.

New Officers of Chicago Medical Society.—At the annual election of the Chicago Medical Society, June 17, the following officers were elected: president-elect, Dr. Ludvig Hektoen; secretary, Dr. Hugh N. MacKechnie; councilors at large, Drs. Jacob C. Crafft, Charles J. Whalen, Samuel J. McNeill, G. Henry Mundt and Clarence B. King, and alternate councilors at large, Drs. John W. Davis, A. Charles Kubicek, Edward E. Reininger, Albert C. Hammett and William G. Alexander.

Personal.—Dr. Winfield Scott Hall, for more than twenty years a member of the faculty of Northwestern University Medical School, Chicago, has been appointed to take charge of the newly organized department of social hygiene of the Presbyterian Board of Temperance and Moral Welfare.——P. J. H. Farrell, Lieut.-Col., M. C., U. S. Army, Chicago, commanding Base Hospital No. 81, reached Newport News, June 16, after more than a year of service on the Western Front.——Dr. Arvid E. Kohler has been appointed city physician of Moline, succeeding Dr. Willis T. Hinman.——Emmett A. Garrett, Lieut.-Col., M. C., U. S. Army, formerly health commissioner of Peoria, who has been on duty overseas, arrived in New York, June 6.

INDIANA

New Medical School Building.—The new medical school building of Indiana University at Indianapolis will, it is announced, be completed and ready for occupancy by the opening of the school year in September. The reports that the entire medical course will be taught at Indianapolis are denied and the premedical courses will be given in Bloomington as before.

Personal.—During the recent meeting of the Mystic Shrine in Indianapolis the health committee was in charge of Dr. Walter S. Given; Dr. James H. Taylor, chief of the medical staff; Dr. Blanchard B. Pettijohn, chief of the surgical staff, and Samuel E. Earp, all of Indianapolis. Substations were also established at the principal hotels, at the fair grounds, and at the Shrine Temple.——Dr. Lester I. Ofner has resigned as superintendent of the Allan County Tuberculosis Sanatorium, near For Wayne, and has been succeeded by Dr. James A. Price of Macon, Ga.

IOWA

Clinic Building Completed.—The clinic building erected by Dr. Elmer E. Bamford at Centerville has just been completed. Dr. Bamford is to be the dental surgeon of the clinic; Dr. Virgil E. Dudman will have charge of the obstetric and gynecologic service; Dr. John I. Marker, internal medicine and the laboratory; Dr. Harvey E. Webb, bone and joint surgery, and Dr. Walter E. West will have charge of the business office. The building contains seventeen rooms, and is well equipped for practical and research work.

Incorrigible Consumptives.—The recent Iowa legislature passed a law: If any person afflicted with tuberculosis carelessly or maliciously expectorates the matter coughed up from his lungs, and after being warned refuses to protect others against the dangers of his infection, then on complaint filed in writing in the district court, the judge may commit such incorrigible consumptive to the state sanatorium, provided there is room, or to any county or private institution for tuberculosis for treatment. It is also provided that if a person afflicted with tuberculosis and under treatment at the state sanatorium or a county or private hospital for tuberculosis refuses to obey the rules and regulations governing such institution and is a general disturber, then, on complaint of the superintendent, the district court may authorize such person to be retained in a room or enclosure in such hospital until such person is willing to comply with the rules and regulations of the institution.

MASSACHUSETTS

Personal.—Walter E. Lang, Major, M. C., U. S. Army, Allentown, Pa., at present on duty at Debarkation Hospital No. 3, New York City, has been appointed superintendent of the Westboro State Hospital, succeeding Dr. Harry O. Spalding, Westboro, resigned.——Dr. Edward P. Worth, Edgartown, has been nominated medical examiner (coroner) for the third Dukes district to fill the vacancy.

Hospital Staff Appointed.—The staff of the Huntington Memorial Hospital, which will assume office, September 1, is as follows: surgeons, Drs. Robert B. Greenough, Channing C. Simmons and Edward H. Risley; assistant surgeon, Dr. George G. Smith; outpatients' surgeon, Dr. George A. Leland; consulting physicians, Drs. Henry A. Christian and Francis W. Peabody; physician, Dr. George R. Minot; laryngologist, Dr. Daniel C. Greene, and assistant physician, Dr. Arlie V. Bock.

Cancer Commission Appointed.—The Harvard Corporation has made the following appointments on the Harvard Cancer Commission: Dr. Robert B. Greenough, director, and Drs. Channing C. Simmons, secretary (both of Boston); Roger Pierce, treasurer; James H. Wright, Boston, pathologist; William Duane, research fellow in physics; William T. Bovie, research fellow in biology; Henry Lyman, Boston, research fellow in chemistry, and Ernest W. Goodpasture, Boston, research fellow in pathology.

Hospital News.—The Plymouth County Tuberculosis Hospital, South Hanson, erected at a cost of $250,000, was dedicated, May 31. The chief speakers were Dr. Eugene R. Kelley, Boston, state health commissioner, and Bernard W. Carey, Winthrop, of the state health department.——Bids have been invited for a hospital building in connection with the Charles Street jail. The proposed building will have on the ground floor the administration offices; the second floor will be for female inmates; the third floor for male inmates, and on the fourth floor will be the auditorium.

MONTANA

Personal.—Dr. Ira A. Leighton has been elected mayor of Boulder.

Health Board Building.—A building for the state board of health is to be erected on the capital grounds at Helena. The building will cost $50,000.

State Association Meeting.—The annual meeting of the Medical Association of Montana will be held in Missoula, July 9 and 10, under the presidency of Dr. Edward W. Spottswood, Missoula. Dr. Edward C. Rosenow of the Mayo Clinic, Rochester, Minn., will lead the discussion on influenza.

Hospital News.—Physicians of Sandstone met the need for a hospital in that district by converting the parish residence into a modern infirmary.——A new hospital is to be built at Harlowton.——Construction of the men's building at the State Hospital for the Insane, Warm Springs, to cost about $42,000 has been authorized by the state board of examiners.

NEW YORK

Conference of Sanitary Officers.—The eighteenth annual conference of sanitary officers, and the first annual conference of the public health nurses of the state of New York were held at Saratoga Springs, June 24 to 26, under the auspices of the New York State Department of Health, and under the presidency of Dr. Hermann M. Biggs, commissioner of health of New York.

New York City

New Building for Jamaica Hospital.—As a result of the success of the first two days' campaign in Queens County to raise $500,000 for the purpose of adding memorial wings to the Jamaica and St. Mary's hospitals, it has been announced that the Jamaica Hospital is to have a new building and that the location of the hospital will be changed to the vicinity of Woodhaven in order to distribute hospital facilities more evenly in Queens.

County Society Refuses to Act Under Health Insurance.—At the regular meeting of the Bronx County Medical Society, held April 16, resolutions were passed to the effect that it was the consensus of opinion of the members of that organization that every member should pledge himself not to act under any Health Insurance Act which might be passed and which had not the support of the Bronx County Medical Society. Cards have been sent to each member of the society requesting him to affix his signature to these resolutions.

Narcotic Drug Research Bureau Established.—In order to meet the acute problems that have arisen in connection with the increasing menace of drug addiction, a Bureau of Narcotic Drug Research has been established, with offices at 47 West Forty-Second Street. The purposes of this bureau are intelligently to study the situation, keep abreast of the times by collecting data both remedial and legislative, bearing on the problem, and to provide machinery by which this information can be disseminated through proper channels. The services of the bureau are at all times at the disposal of the physician, the medical press and the drug addicts. On file are numerous treatises on drug addiction prepared by authorities, together with the personal histories of a large number of addicts, all of which have been checked up in the minutest detail. Advice is given to the addict as to the best means of obtaining treatment. The bureau is under the executive management of A. R. Parkhurst, and its energies will be concentrated, for a time at least, on propaganda of an educational nature with the hope of arousing the physician to the necessity of studying narcotic drug addiction as a disease and not as a vice.

OHIO

Suits Decided.—In the case of W. G. Maney against Dr. Edward C. Banker, Akron, in which damages of $25,275 were claimed on allegation of malpractice in the operation for gallstones, the jury, June 4, returned a verdict in favor of Dr. Banker.——Dr. Moritz Loewenthal, Cleveland, is said to have been found guilty on eight counts of the illegal disposition of narcotics.

Personal.—Dr. Howard H. Smith, Bucyrus, has been appointed director of health of North Yakima, Wash.——Charles M. Hendricks, Major, M. C., U. S. Army, Eaton, has been promoted to the rank of lieutenant-colonel, M. C.——Charles T. Souther, Capt., M. C., U. S. Army, Cincinnati, was elected president of the Ohio branch of the National Pharmaceutical Service Association, May 20.——Dr. Elfie R. Graff, Glendale, Cincinnati, will shortly sail for her new professional duties in Turkey.——Dr. Horace M. Corns, Alliance, has been appointed resident physician in the medical service of Lakeside Hospital, Cleveland.——Dr. George R. Love, Toledo, for twenty years superintendent of the Toledo State Hospital, has resigned.

PENNSYLVANIA

Philadelphia

Personal.—At the meeting of the board of directors of the city trust Dr. Thomas B. Holloway was appointed to fill the vacancy created by the resignation of Dr. Joshua E. Sweet as attending surgeon at the Wills Eye Hospital. Dr. Orla J. Park was appointed resident surgeon, and a certificate of service was granted Dr. R. S. Pendexter in recognition of his faithful services as resident physician at that hospital.——Dr. Alexander C. Abbott, who recently returned from France, where he served with the Medical Corps of the U. S. Army, has been nominated for a position on the board of health. Dr. Frank C. Hammond, who was appointed to fill the vacancy insisted on resigning the post that Dr. Abbott might be reappointed to his former position.

Medicopsychologic Conference.—The Medico Psychological Association held a three day session at the Bellevue-Stratford Hotel, June 18, 19 and 20. Col. Thomas W. Salmon, M. C., from New York City, who was in charge of the neuropsychiatric division of the A. E. F., criticized the care of mental cases aboard transports. Col. Pearce Bailey of New York, who was in charge of the neuropsychiatric division in the Surgeon-General's Office in Washington, also spoke of the crowded ships, but in charts showing the cause of rejection in the army he pointed out that of the 67,417 rejections from neuropsychiatric causes, only 3 per cent. of this number, or fewer than 2,000, were drug addicts and fewer than 5 per cent. of the total army rejections were attributed to drugs and alcohol combined. The following officers were elected: Dr. Henry C. Eyman of Massillon, Ohio, president; Dr. Owen Copp, Philadelphia, vice president, and Dr. Harry W. Mitchell, Warren, Pa., secretary and treasurer.

TENNESSEE

Laboratory Building for Memphis College.—At a meeting of the board of trustees of the university of Tennessee held in Nashville, June 2, it was decided to spend $100,000 for a laboratory building for the medical department of the university, located in Memphis.

Hospital Notes.—The contract for the construction of the Fort Sanders Hospital, Knoxville, has been awarded. The founders of the institution are: Drs. Leon L. Sheddan, Louis A. Haun, John P. Tillery, Oliver W. Hill, Merk M. Copenhaver, John B. Thielen, and Edgar H. Ford, all of Knoxville. The building will accommodate sixty patients and will have special wards for obstetrics and the care of infants. It will cost $100,000. A charter has been applied for.

CANADA

Prescribing Liquor.—Physicians in Toronto, and other parts of Ontario, are now speculating as to what action the Ontario Medical Council will take with some fifty physicians in that city who, each in a month, have found it necessary to prescribe 200 quarts of whisky for their respective patients. It is said that in other cities physicians have been equally generous with the interpretation of the Ontario Temperance Act.

Personal.—Sir Arthur Newsholme gave a public address, Friday evening, June 20, in Convocation Hall, Toronto. The subject was: "Some Problems of Preventive Medicine of the Immediate Future." Sir Arthur was the guest of honor at a dinner given by Dr. Edmund E. King, Toronto, president of the Academy of Medicine.——Dr. Ezra H. Adams, Toronto, epidemiologist of the department of public health for that city, has been appointed health officer to the border cities and towns of Ontario, with headquarters at Windsor.——Col. Perry G. Goldsmith, Toronto, who was one of the first Toronto physicians to go overseas, has been appointed a Commander of the Order of the British Empire.——Lieut.-Col. C. E. Cooper Cole, Toronto, who has been in command of Witley Camp Hospital, England, has been appointed a Commander of the Order of the British Empire.——Major Frederick A. Cleland and Lieut.-Col. Cameron A. A. Warren, Toronto, have arrived home from Siberia.

LATIN AMERICA

Children's Hospital in Venezuela.—At the end of last March there was opened at Caracas a children's hospital with funds furnished by wealthy persons of that capital.

Tuberculin Testing in Uruguay.—The congress of Uruguay has voted, on recommendation of the president, the sum of $20,000 to enforce the law, recently enacted, providing for the compulsory testing with tuberculin of all milch cows.

New Public Health Buildings in Guatemala.—During the year 1918 there was established a Vaccination Institute in Guatemala, and, in addition, the Mothers' Asylum was rebuilt and there were built four new wards in the General Hospital of Guatemala.

Public Health Expenses in Guatemala.—During the year 1918, there was expended in Guatemala over 18,000,000 *pesos* for public health and public assistance work, distributed as follows: 1,961,624 *pesos* for public health purposes and 16,325,838 for public assistance.

Temperance Zones in Paraguay.—A new law enacted in Paraguay provides for the creation of temperance zones within which no alcoholic drinks can be either manufactured or sold. The temperance zones will be fixed by the president and any industrial establishment, in order to be considered a temperance zone, must have at least 100 permanent employees.

Workmen's Compensation Legislation in Brazil.—The president of Brazil has recently approved the law on industrial accidents which requires employers to pay a certain compensation to workers, victims of accidents, or their families in case of death. Employers are also compelled to give all necessary medical, pharmaceutical and hospital relief. The regulations for the enforcement of the law were approved by the president, March 12.

Prophylaxis of Venereal Disease.—The *Semana Médica* of Buenos Aires relates that all of the public attending the film version of "Damaged Goods," while it was being presented there, were given a Spanish translation of Fournier's small pamphlet, "For Our Sons When They Are Eighteen." This pamphlet was published in Spanish in Argentina in 1907 by the Sociedad argentina de profilaxis sanitaria y moral. The enterprise of the moving picture producer is lauded by our exchange which states that many of the resident physicians have made a point of congratulating him.

Interchange of University Professors.—The *Revista Médica del Uruguay* states that Professor Maira, interchange professor from Chile at Montevideo, recently delivered three addresses there, "Medicine in Chile," "Mineral Hot Springs in Chile," and "Treatment of Asthma with Epinephrin." The Sociedad de pediatria held a special session in his honor, the Club Médico del Uruguay entertained him, and the governor of the republic tendered him a banquet at which the rector of the university presided, and to which the leading men in the official medical world had received special invitations.

Reorganization of the National Public Health Service in Argentina.—The members of the newly appointed Consejo

Consultativo de Higiene met recently in one of the halls of the Departamento Nacional de Higiene, Dr. E. R. Coni presiding, and appointed committees for different branches of the work outlined. Dr. Coni was charged with the task of drawing up a new sanitary code for the country, and a special committee was appointed to study the subject of influenza. This committee consists of Drs. M. R. Castex, D. Decoud and Julio Méndez. Dr. Coni presented for the consideration of the council a proposed regulation for requirement of a medical certificate before marriage.

Uruguayan Professors in Buenos Aires.—The dean of the medical faculty of the University of Montevideo has appointed the following members of the faculty as interchange professors to go to Buenos Aires: Dr. H. G. Lagos to deliver in May a lecture on the "Surgical Treatment of Gastric and Duodenal Ulcers"; Dr. S. C. Rossi, to lecture in June. The lecture in July by Dr. J. F. González is to be on "Avariosis," and by Dr. J. Pou Orfila in August, "La patología general ginecológica y el estudio de las metabolismopatías y endocrinopatías." During September, Drs. J. B. Morelli and A. Navarro will each deliver a lecture, respectively, entitled "Heliotherapy and Thalassotherapy in Pulmonary Tuberculosis," and "Surgery of the Pylorus." The *Revista Médica del Uruguay* adds to this notice that the names of the professors to be sent from Buenos Aires to Montevideo have not yet been published.

GENERAL

American Society for Clinical Investigation Elects Officers.—For the year 1919 the American Society for Clinical Investigation has elected the following officers: president, Warfield T. Longcope, New York; vice president, R. T. Woodyatt, Chicago; treasurer, Alfred F. Hess, New York; secretary, Walter W. Palmer, New York; council, George Blumer, New Haven, Conn.; Roger Lee, Cambridge, Mass., and Ernest E. Irons, Chicago.

Chemical Industry Exposition.—The fifth exposition of chemical industries will be held in the First Regiment Armory, Chicago, during the week of September 22. September 22 and 23, the American Institute of Mining Engineers will occupy the stage. The American Electrochemical Society and Technical Association of Pulp and Paper Industry, September 25 to 27, inclusive. A symposium on Safety in the Plant and Mine will occupy one afternoon. M. L. Leopold, safety engineer of the U. S. Bureau of Mines, will preside at this symposium, and in the evening a series of motion pictures of safety work in plants, fields and mines will be shown.

Annual Meetings of Special Societies.—The American Pediatric Society at its annual meeting, in Atlantic City, June 16 to 18, elected the following officers: president, Dr. Thomas S. Southworth, New York; vice president, Dr. Alfred Hand, Jr., Philadelphia; secretary, Dr. Howard Childs Carpenter, Philadelphia; treasurer, Dr. Charles Hunter Dunn, Boston, and recorder and editor, Dr. Oscar M. Schloss, New York City.——The American Climatological and Clinical Association, at its annual meeting, held in Atlantic City, June 14 to 17, elected the following officers: president, Dr. Lawrason Brown, Saranac Lake, N. Y.; vice presidents, Drs. Charles W. Richardson, Washington, D. C., and Dr. Josiah N. Hall, Denver; secretary, Dr. Arthur K. Stone, Framingham Center, Mass., and councilor, Dr. Guy Hinsdale, Hot Springs, Va.

Proposed Legislation.—The following bills are under consideration in the United States Senate:

No. 563, introduced by Senator Fletcher, to amend an act entitled "An Act to appoint Joseph Y. Porter, Key West, Fla., a lieutenant-colonel and deputy surgeon-general and to place him on the retired list of the Army."

No. 559, introduced by Senator Williams, to authorize certain late physicians and surgeons of the United States Volunteer Army in the War with Spain to practice their respective professions in any territory, district, dependency or possession of the United States, under the constitutional jurisdiction of Congress upon the presentation and proof of certain facts.

No. 813, introduced by Senator Owen, to establish a sanitary reserve corps for the Public Health Service.

No. 814, introduced by Senator Owen, to establish a department of health and for other purposes.

The following bills have been introduced in the House:

No. 2484, introduced by Representative Webster, to provide for the restoration to their former positions and rank medical employees in the Public Health Service who resigned such services to enlist in the war with Germany.

No. 2482, introduced by Representative Baker, to grant rank to the Army Nurse Corps.

No. 3080, introduced by Representative Nolan, to commission acting assistant or contract surgeons of the United States Army who have served in the Army for a period of at least three months to be first-lieutenants in the Medical Reserve Corps of the Army in case of necessity.

House Joint Resolution 53, introduced by Representative Montague, to restore John B. H. Waring, Richmond, Va., late a Captain in the Medical Corps, the files of which he was deprived, and place him on the retired list.

Bequests and Donations.—The following bequests and donations have been recently announced:

Lynn Hospital, Lynn, Mass., $100,000, by the will of the late Walter H. Breed, Lynn.

In memory of Capt. Chauncey B. Keep, and to be used as an endowment for an infirmary for Yale University, a donation of $54,000 in securities by Mr. and Mrs. Chauncey Keep and Mrs. Katherine Keep of Chicago.

St. Joseph's Hospital, Philadelphia, for the benefit of its social service department about $5,000, the proceeds of a lawn fête.

Jefferson Medical College, Philadelphia, $5,000 for the endowment of a free scholarship; Rush Hospital, for free beds in memory of Frances B. Tyson, $5,000, and Pennsylvania Training School for Feeble-Minded, Elwyn, and for "such medical and surgical treatment as shall contribute to the relief of mental and physical defects of defective classes, inmates of the institution," $2,000, by the will of Dr. J. Ewing Mears.

Episcopal and Pennsylvania Hospitals in Philadelphia, each $200,000; University of Pennsylvania Hospital, Orthopedic Hospital, Women's Medical Hospital of Philadelphia and Children's Hospital of Philadelphia, each $100,000; Polyclinic Hospital, Philadelphia, $50,000; Pennsylvania Training School for Feeble-Minded, Elwyn, $25,000, and Jefferson Medical College, Philadelphia, $10,000, by the will of Harriet Blanchard.

Toronto charities, including the Toronto General Hospital, and Home for Incurables, $500,000, by the will of William Ramsay.

Elizabeth Garrett Anderson Hospital, London, England, $5,000 for the endowment of a Canada bed in the hospital donated by the Elizabeth Garrett Anderson Memorial Fund.

Public Health Legislation.—A movement to create a Department of Public Health in the federal government has been launched in Congress in the form of a bill introduced by Congressman John McDuffie of Alabama, which authorizes the President to appoint a secretary of public health at a salary of $12,000 who is to be the head of the department. The organization of bureaus is left to Congress, but the President is authorized to transfer to the new department all government bureaus now devoted to public health work. The records and office equipment of the existing health bureaus are also to be transferred. The secretary of public health shall have personal jurisdiction and supervision of all public health matters of the federal government, except those of the medical departments of the Army and Navy. The measure provides for the organization of the following bureaus: sanitary research, vital statistics and publications, foods and drugs, quarantine, sanitary engineering, government hospitals and personnel and accounts. Additional bureaus may be established by the secretary with the approval of the President. The cooperation of state health organizations is authorized and the organization of a health board of the state health representatives is arranged for, to serve in an advisory and cooperative capacity, but without legal powers. The sum of $10,000,000 is appropriated to be used as follows: for the establishment of a homogeneous system of health administration in the respective states, $1,000,000; for rural sanitation, $2,000,000; for the control of communicable diseases, including tuberculosis, venereal diseases, malaria, hookworm, etc., $5,000,000; for scientific study of the causes and manner of transmission of disease, $2,000,000. It is provided that "it shall be the specific duty of the Department of Public Health to foster and promote all matters pertaining to the conservation and improvement of the public health and to collect and disseminate information relating thereto." It is known that there is considerable sentiment in Congress for a strong public health department, although Congress is not generally in favor of additional governmental expenditures. The President would have the authority to make the secretary of public health a member of his cabinet if he chose.

FOREIGN

Prizes Offered by Turin Academy of Sciences.—The Reale Accademia delle Scienze of Turin, Italy, announces that the Vallauri prize of 26,000 lire ($5,200), is to be awarded for the best work on any of the physical sciences that was published in the four years ending Dec. 1, 1918. The prize is open to foreigners as well as to Italians. The works sent in to compete for the prize must reach the Academy, Via Po 18, Turin, before Dec. 31, 1919. A further prize of 1,200 lire is offered for the best manuscript or article published since Jan. 1, 1915, on the etiology of endemic cretinism. The *Gazzetta degli Ospedali* adds to the above notice that none of the works sent in to compete for these prizes will be returned.

PARIS LETTER

Paris, June 5, 1919.

Physicians on Disability Boards

The chamber of deputies has just passed a bill that had been adopted previously by the senate, so that it thus becomes a law. This law changes completely the personnel of disability boards. Until now, these boards were composed of a president, who was a general or a colonel belonging to the regular army, a recruiting officer, an officer of the gendarmerie, and a member of the commissary department. Physicians attended the sessions only in the capacity of experts to give their advice when requested. From now on, the disability boards will have the following personnel: an inspecting physician or chief surgeon as president; a "médecin-major" of the first or second class, and two officers belonging to the army corps in the field, to be appointed by the general commanding the division and to be of a rank inferior to that of the inspecting chief surgeon who acts as president. In case of disagreement, the president has the deciding vote. This gives absolute control in the discussions to the physicians, who up to the present time have acted only in an advisory capacity. A recruiting officer and a member of the commissary department will be present at the meetings without having any consultative or deliberative power. They will only have to record the results of the discussions.

Roentgenology in the Army Medical Corps During the War

At a recent meeting of the Académie de médecine, Dr. Haret, instructor in roentgenology in the hospital Saint-Antoine, reported the progress of the roentgenologic service during the war. At the beginning of hostilities there were ten base and eleven transport roentgenologic stations. There was a shortage of motor trucks specially equipped for roentgenologic work and also of specially trained personnel. When, in 1915, the surgical motorcars were introduced, every unit was provided with a special truck for roentgenologic work. In 1918, there were 400 roentgenologic units for the army and 450 for the country at large. Before the war there were only 175 graduate roentgenologists in France. Courses were established at l'Ecole d'application de médecine et de pharmacie militaires de Val-de-Grâce, and when the armistice was signed there were 840 physicians in the roentgenologic service, with 1,010 male and 175 female assistants. This material and these units will be used now in some of the hospitals of the provinces in order that all the surgical clinics may be in a position to use at the bedside of every patient or in the operating room the necessary roentgen control.

The Union des Femmes de France

The Union des Femmes de France (one of three societies that compose the French Red Cross) has just met in a general assembly under the presidency of Mme. Perouse. The report of the secretary brought out the great increase in the work of the society during the last few years. Of the 90,000 members, more than 60,000 have been actively devoted to the various branches of work of the society in Paris and in the provinces. In more than 365 auxiliary hospitals, the society has opened clinics, nurseries and dispensaries for children and adults, welfare centers for soldiers, centers for the reeducation of the war-injured, canteens at railway stations, etc. The number of nurses that have served in the auxiliary hospitals of the Union des Femmes and in the military sanitary units of France and of the allied nations is 20,000. Forty-five have died on the field of honor or as a result of sickness contracted during the performance of their duties. Besides, the Union des Femmes has created important antituberculosis centers at Tonnay-Charente, Monbran, Menton, Berck-Plage, and other places, and they have opened forty-five relief stations in the devastated regions. Most of these furnish lodging and meals, when necessary; contain a dispensary, and maintain a distribution service in the villages of the neighborhood. In Alsace and Lorraine, eleven committees have been organized. The union has spent during the war the sum of $19,000,000.

A Gift of 10,000 Francs for the Institute of Child Welfare

I reported in my preceding letter the generous gift made by the American Red Cross for the purpose of creating in the Faculté de médecine de Paris an institute for child welfare on condition that one million francs should be collected in France for the same object. Dr. G. Variot, vice president of the Société de médecins des hôpitaux de Paris and chief of the services of the Institut de puériculture de l'Hospice des Enfants-Assistés, desiring to contribute to the fund, has sent to the dean of the Faculty of Medicine the sum of 10,000 francs.

Promotion of Physical Culture

M. Paté, deputy for Paris, has transmitted to the chamber of deputies a bill that provides compulsory physical training for the young men of France.

An American Mission in France

An American mission composed of about ten professors from American universities, escorted by Mr. MacDougal Hawkes, president of the French Institute of the United States, has just arrived at Havre. The object of the mission is, among other things, to visit our institutions of higher learning in Paris and in the provinces as well, and to promote more cordial social and intellectual relations between these French institutions and similar institutions in the United States, to which end it is proposed to send American students to France and French students to the United States.

Death of Dr, Dominici

The death of Dr. Dominici at the age of 54 years has been reported. He was known for his work on radium and its various rays.

Personal

At the meeting of May 22, the council of the Faculty of Medicine of Paris appointed as professor of general pathology and therapeutics Dr. Gouget, previously an associate professor of the same faculty. The council has also appointed to the chair of parasitology and natural history Dr. Brumpt, previously associate professor and chief of parasitic research. Dr. Brumpt succeeds the late Professor Blanchard.

Anomalies of the Thermic Curve in Cardiac Irritability

At one of the recent meetings of the Société médicale des hôpitaux de Paris, Dr. Laubry, physician of the hospitals, and Dr. C. Esmein, chief of the clinic of the Faculty of Medicine of Paris, declared that they have often observed that in cases of cardiac irritability there is a tendency to hyperthermia. Generally speaking, this tendency is not marked and manifests itself only by a slightly thermic shift from time to time. This gives to the thermic curve an irregular aspect while remaining, as a whole, within the normal limits. Sometimes the temperature, which has shown hardly any change in the morning, rises during the evening (either from time to time or daily), reaching around 100 F. This phenomenon has been proved, by means of a careful inquiry, to be independent of malingering. It occurs in persons who have been engaged in some kind of physical or mental activity just before the temperature was taken. An hour in bed causes it to disappear, or at least reduces it considerably. It presents thus the essential characteristics of hyperthermia caused by fatigue at the onset of pulmonary tuberculosis. However, Laubry and Esmein never have seen any patients with an irritable heart and presenting this anomaly in their thermic curve who developed pulmonary tuberculosis later on. Nor were they able to connect this phenomenon with any infectious complication. It would seem that this manifestation is produced by the irritability of the heart or, speaking more correctly, it would appear to be the effect of the morbid mobility of the nervous system giving origin to the cardiac irritability. These data confirm the theory of Küss and others as to the polymorphic etiology of fever resulting from fatigue and would seem to invite caution in explaining this phenomenon in cases of cardiac irritability.

Dr. A. Siredey has observed a certain number of cases of this kind among his patients. A notable instance was the case of the son of one of his colleagues. From his fifteenth to eighteenth year he presented this form of hyperthermia, having a temperature every evening of from 100.4 to 100.9 and sometimes 102.2 after a long walk. He was not found to have any kind of organic lesion. Later on, this young man developed normally and has served through the whole war without presenting the slightest pathologic symptom.

Dr. C. Aubertin has emphasized the importance of these febriculae, for, during the war, many soldiers presenting these symptoms have been considered tuberculous and have been granted disability claims that were not justified. Dr. Halle has observed a series of cases presenting similar symptoms. Sometimes this instability of temperature persists for several years. It generally occurs in nervous impressionable children, and especially in well-to-do families, in which every one overeats; gout is common and sour stomach and vomiting spells prevail. In most cases one cannot find in these persons any organic lesions or any sign of tuberculosis. The best thing to do is simply to remove the cause; for in most of the cases the trouble straightens itself out.

Dr. Nobécourt, associate professor of the Faculty of Medicine of Paris, states that these cases are found not only in well-to-do families: they are also seen in the hospital. He has observed, together with Dr. Merklen, in the Hôpital des Enfants-Assistés, a rise of temperature after play, but this disappears after half an hour's rest. Thermic reaction after a walk, though important in an adult from a semeiologic standpoint, is of very little value in a child unless it still persists after an hour and a half of rest. The clinical examination and the tuberculin test have demonstrated that these children cannot be considered tuberculous.

Dr. Emile Sergent has seen a number of these cases in the army, among those claiming to be tuberculous. Thermic instability can also often be observed in women, and not infrequently in similar cases one can see signs of hyperthyroidism, especially among young girls at the beginning of puberty or in women as the menopause approaches. Sergent believes that these factors offer an explanation for not a few cases of this kind.

LONDON LETTER

London, May 28, 1919.

Subsidized Parentage

Evidence has been given before the National Birth Rate Commission in favor of the endowment of motherhood by the state. In opposition to this, Mr. Harold Cox, the leading individualist politician of the day, pointed out that the population of England and Wales doubled in the sixty years that ended in 1911. Suppose that rate of increase were continued indefinitely, then in the year 2201 the population of England and Wales alone would be 2,295,000,000. No further argument was needed to prove that the rate of increase in the population must decline as the volume grows. The rate could only be reduced either by diminishing the birth rate or by increasing the death rate. If birth control were in itself immoral, it would still be immoral when our population had reached such a volume that a reduced rate of increase became necessary. A high infantile death rate was the almost invariable accompaniment of a high birth rate. Thousands of children were fated only to live a few weeks or a few months. This involved a vast waste of human effort. In the East the waste of women's bodies and of infant life was even more appalling. Both in India and in China, out of every thousand children born often more than 500 died. The socialist proposal to give a state subsidy to every woman who produces a child would only increase the evil. Children reared by subsidized parents would probably lounge through life leaning on the state. The Germans established a few years ago an imperial grant to mothers who suckled their babies. Last year's Local Government Board report on infant welfare in Germany says: "It is recorded from a large number of centers that mothers discontinue breast-feeding immediately the imperial allowance ceases, regardless of the well-being of their infants." It would be futile to deal with the German peril by means of what might be called a cradle competition. In such a contest we must inevitably be beaten, because Germany started the race with a much larger volume of population. England at the present moment was overpopulated. Doubtless considerable improvement would be effected if our industries could be established in garden cities. But if this process were carried to the point of giving all our overcrowded millions a quasirural surrounding, there would be no real country left. Our island was too small to afford possibilities for a full life to all the millions now crowded on it. He therefore welcomed the decline in population, and hoped it would continue.

The Ministry of Health Bill and the Nostrum Evil

In a previous letter to The Journal was described the attempt of the House of Lords to deal with the nostrum evil in connection with the ministry of health bill. A further motion has been made by Lord Bledisloe, who said that the law to a large extent provided for the protection of those purchasing on the strength of fraudulent advertisements, quack and sometimes poisonous drugs and suffering in health thereby, but that no department considered it its special duty to institute prosecution. Replying for the government, Viscount Sandhurst said that further consideration had been given to this very important subject. But the more it was considered, the more difficult and complicated it was found to be. The departments concerned were the Local Government Board, the customs and excise, the Privy Council, the post office, and the Home Office. The amendment really stated the law as it stood; it did not propose any new power. So far as the Local Government Board was concerned, the new minister would take over powers and duties which would include the food and drugs act of 1875, but proprietary medicines were specifically excluded from that act. The customs and excise prosecuted for breaches of law in connection with the stamp duty, among others, venders of "patent medicines." But that was a revenue matter, and must be left in the hands of the revenue authorities. The Privy Council was indirectly concerned in connection with the Pharmaceutical Society, which prosecuted for the illegal sale of poisons. The post office prosecuted for the transmission of indecent matter through the post. That was a subject of post office administration, and could not be transferred to another department. The Home Office might receive complaints, but it was the business of the aggrieved person or of the local police to prosecute, and for these purposes the local police were not under the Home Office. Nothing more could be effected so long as the law remained unchanged, but the public prosecutor was, in grave cases, at the service of any department. As soon as the minister could, he would suggest amendments in the law. The government hoped that Lord Bledisloe would be satisfied with this assurance. Eventually, at the suggestion of the lord chancellor, it was agreed that he, Viscount Sandhurst, the attorney general, and director of public prosecution, should confer so as to be able to make a proposal.

Creation of Directorates of Hygiene and Pathology Within the Army Medical Department

Official sanction has been given to an important reform brought forward by Sir John Goodwin, director-general of the army medical service—the linking-up under a definitely planned organization of the activities of the different departments and of the persons hitherto concerned with the various problems of preventive medicine, pathology and tropical diseases bearing on the health of the army in peace and war. The need for such a reorganization had long been felt, but not until the war brought wider recognition of the benefits of scientific research and the amount of training, work, and organization required to obtain the best results did the urgent need for a better system become manifest. The principal objects are: (1) To utilize to the fullest extent the benefits of new knowledge, as these become available, through close cooperation between those working within and outside the army and by initiating and controlling research work in connection with problems affecting the health of the troops; (2) to raise the standard of sanitary and pathologic work in the army by creating within the army medical department such an organization as will ensure this cooperation and will, at the same time, furnish inducement to officers who have specialized in these subjects to continue to work therein. It is also hoped that the improved prospects now opening up may encourage young medical men whose bent and inclinations lie in these directions to enter the service. The scheme is as follows: Two new directorates of hygiene and pathology, respectively, have been created under the director-general, army medical services, as a part of the war office organization of the army medical department. These directorates will be directly responsible to the director-general for all matters relating to their respective spheres, and they will take over from the various branches of the army medical department the sections of this work which have hitherto been distributed among those branches. Advisory committees will be appointed to assist the directors, composed of both military and civilian members. Their constitution will be as follows:

Hygiene Advisory Committee.—Chairman: The director of hygiene; vice chairman: The deputy director of hygiene. Members: The professor of hygiene at the Army Medical College, a representative of the Directorate of Fortifications and Works, a sanitary engineer, a civil professor of hygiene or a health officer of a county or large city, a physiologist, and a representative of the medical department of the Local Government Board.

Pathological Advisory Committee.—Chairman: The director of pathology; vice chairman: The deputy director of pathology. Members: The professor of pathology, Army Medical College; the professor of tropical medicine, Army Medical College; two civilian professors or recognized experts in pathology; a civilian professor or expert in tropical medicine, and a representative of the Medical Research Committee.

Marriages

ESDRAS JOSEPH LANOIS, Lieut., M. C., U. S. Navy, to Miss Gertha Haines, Portsmouth, N. H., at Somerville, Mass., June 7.

JOSEPH FRANK BLAKE, Chadbourn, N. C., to Miss Eva MacDonald of Wilmington, N. C., May 31.

RALPH ALLEN WILCOX to Miss Stella Judson Murgittroyd, both of Phoenix, N. Y., June 12.

GOODRICH TRUMAN SMITH to Miss Amparito Farrar, both of New York City, June 2.

CHARLES BERNARD RENTZ, Sanborn, Iowa, to Miss Ruth Miller of St. Paul, June 9.

HARRY LEE HUBER to Miss Eleanor Johnson, both of Chicago, June 14.

Deaths

William Clark Payne, Marshalltown, Iowa; Western Reserve University, Cleveland, 1853; aged 88; assistant surgeon of the Ffty-Sixth Ohio Volunteer Infantry, and later of the Twenty-First Ohio Volunteer Infantry during the Civil War; for more than forty years a practitioner of Marshalltown; died, June 4, in a sanatorium in Bozeman, Mont., from senile debility.

Paul C. Ohaver, Fullerton, Neb.; Keokuk Medical College, College of Physicians and Surgeons, Keokuk, Iowa, 1904; aged 45; a member of the Nebraska State Medical Association and president of the Nance County Medical Society in 1915; mayor of Fullerton in 1913; died in the Matson Hospital, Columbus, Neb., June 8, from valvular heart disease.

Benjamin Delos Paul, Indianapolis; Harvard Medical School, 1918; aged 28; formerly an intern in the Boston State Hospital; who had been a first lieutenant, M. C., U. S. Army, and was honorably discharged, January, 1919; was injured in a collision between automobiles, recently, and died after two hours at the Reid Hospital, Richmond, Ind.

Paul Lange Cort ⊕ Trenton, N. J.; Jefferson Medical College, 1895; aged 48; assistant physician to the New Jersey State Hospital, Trenton, from 1897 to 1904, and thereafter consulting neurologist; attending physician and pathologist to Mercer Hospital; a member of the common council of Trenton in 1907; died at his home, June 12, from heart disease.

George Stillman Browning ⊕ Sioux City, Iowa; University of Illinois, Chicago, 1899; aged 44; formerly professor of principles and practice of medicine, electrotherapeutics and electrodiagnosis in the Sioux City College of Medicine; local surgeon to the Illinois Central Railroad; died at his home, June 8, from multiple neuritis.

John Joseph Ashley, Brooklyn and St. Cloud, Fla.; New York University, New York City, 1884; aged 75; a veteran of the Civil War; medical director for the state of New York of the Grand Army of the Republic in 1890; died at his home in St. Cloud, April 11, from asthma.

Harry J. Haiselden, Chicago; University of Illinois, Chicago, 1893; aged 49; died in Havana, Cuba, June 18, from cerebral hemorrhage. Dr. Haiselden attained considerable notoriety in 1915 through publicity concerning refusal to operate on a congenitally defective infant.

James T. Evans, Pascagoula, Miss.; University of Louisville, Ky., 1873; aged 67; a member of the Mississippi State Medical Association, and once president of the Jackson County Medical Society; died at his home, April 20, from bronchopneumonia following influenza.

Thomas Henry Becker, Bluefield, W. Va.; Jefferson Medical College, 1911; aged 33; a member of the West Virginia State Medical Association; died suddenly in Jefferson Hospital, June 8, from heart disease, believed to have been due to the use of headache powders.

Peter E. B. Robertson, Gainesville, Ga.; Medical College of Georgia, Augusta, 1891; aged 52; twice mayor of Gainesville; cranked his car while it was in gear near Gainesville, June 8, and was run over by the car and instantly killed.

Thomas Benton McCown ⊕ **Major, M. C., U. S. Army,** San Diego, Calif.; Northwestern University Medical School, Chicago, 1893; aged 51; on duty at military headquarters, El Paso, Texas; was found dead in his office, June 16, from heart disease.

Hiram L. Lutz ⊕ Philadelphia; University of Pennsylvania, Philadelphia, 1900; aged 40; a specialist in ophthalmology; clinical chief of the eye dispensary in his alma mater; died in the University Hospital, June 8, after an operation for tumor.

Benjamin A. Garr, Louisville, Ky.; Hospital College of Medicine, Louisville, 1877; aged 65; at one time state medical examiner for the Ancient Order of United Workmen; died at his home, June 9, from cerebral hemorrhage.

John Kinghorn Lawson ⊕ **Lieut., M. C., U. S. Army,** Dayton, Ohio; Ohio State University, Columbus, 1916; aged 25; on duty in a base hospital near Paris; died in that institution, May 8, after an operation for appendicitis.

Paul Bartholomew Work ⊕ Elkhart, Ind.; University of Michigan, Ann Arbor, 1911; aged 33; who was under treatment for diabetes at the Mayo Brothers sanatorium, Rochester, Minn.; died in that institution, June 7.

Harry Minhern Lavelle ⊕ **Capt., M. C., U. S. Army,** Pittsburgh; Jefferson Medical College, 1900; aged 44; on duty with the American Military Mission in Berlin; died in that city, May 28, following a surgical operation.

James Edward Crook, Jacksonville, Ala.; Vanderbilt University Nashville, Tenn., 1883; a member of the Medical Association of the State of Alabama; died in a hospital in Atlanta, Ga., about June 9.

James Winfield Small, Alpena, Mich.; Hahnemann Medical College, Chicago, 1889; aged 59; a member of the Michigan State Medical Society; died at his home, May 22, from valvular heart disease.

William E. Lloyd, Jr., Forest City, Pa.; Baltimore Medical College, 1894; aged 46; died in the Mid-Valley Hospital, Olyphant, Pa., June 2, three days after an operation for appendicitis.

William N. Unkefer, Piqua, Ohio; Cincinnati College of Medicine and Surgery, 1879; aged 65; died in the Memorial Hospital, Piqua, June 4, after an operation for the removal of gallstones.

Hiram R. Thomas, Flint, Mich.; American Eclectic Medical College, Cincinnati, 1893; aged 74; died at the Wabash Valley Sanitarium, Lafayette, Ind., June 5, from a nervous breakdown.

Andrew E. Johnson, Cloquet, Minn.; University of Minnesota, Minneapolis, 1891; aged 57; died in a hospital in Duluth, Minn., June 3, from carcinoma of the liver.

Aaron S. Sensenich ⊕ Wakarusa, Ind.; Rush Medical College, 1881; aged 69; died at his home, June 4, from cholelithiasis, complicated by diabetes.

William Wesley Cole, Silver Creek, N. Y.; Cleveland University of Medicine and Surgery, 1890; aged 60; died at his home, April 8, from diabetes.

William Augustus Burns, Philadelphia; University of Pennsylvania, Philadelphia, 1869; aged 75; died at his home, June 8, from heart disease.

Samuel N. Holland, Lavonia, Ga.; Medical College of the State of South Carolina, Charleston, 1880; aged 69; died at his home, May 17.

John A. J. Penny, Neuse, N. C. (license, North Carolina, 1885); aged 76; a practitioner for fifty-seven years; died at his home, June 6.

George A. Wise, Benton, La.; Tulane University, New Orleans, 1876; aged 68; died in a sanatorium in Shreveport, La., June 5.

Greggar Smedal ⊕ La Crosse, Wis.; Rush Medical College, 1903; aged 44; a specialist in surgery; died about June 1.

H. Watson Smith, Folsom City, Calif.; Rush Medical College, 1870; aged 75; died at his home, May 27, from tuberculosis.

Jacob O. Knipe, Norristown, Pa.; Jefferson Medical College, 1862; aged 82; died at his home, June 5.

Frank M. Ewing, Lincoln, Ill.; Jefferson Medical College, 1882; aged 62; died at his home, June 5.

Correspondence

"FAS EST ET AB HOSTE DOCERI"

To the Editor:—Let us have no more abstracts from the *Deutsche medizinische Wochenschrift.*

Charles D. Ryan, M.D., Kokomo, Ind.

To the Editor:—I endorse every word he [Dr. Ross G. Loop] has written, and cannot understand how any one who has tried to learn what the Germans have done during the past decade wants their products of any kind.

F. A. Butterfield, M.D., Dakota, Ill.

To the Editor:—I certainly heartily approve of every word of Ross G. Loop of Elmira, N. Y., in the issue of June 7, 1919, against any more German literature. I will see that every copy of mine of The Journal of the American Medical Association is burned on receipt of same if ever I find any of that propaganda, and I think every other Eaton County doctor will do the same. I will do all I can to help do it. We are through with anything German in any form—schools and all.

F. W. Sassaman, M.D., Charlotte, Mich.

To the Editor:—I note with pleasure Dr. Ross G. Loop's communication in The Journal, June 7, 1919. As a medical officer who served in France for twenty-one months and one who has seen first hand the wanton destruction of that country, I heartily concur in his sentiments. I wish that it were possible at least temporarily to revoke the privileges of our medical societies to many German physicians and surgeons. Their attitude of supercilious condescension has always been a most unpleasant note; and as Dr. Loop remarks, are we so dependent on them for our scientific pabulum? As I write this, a card has come to hand from a German physician practicing in Carlsbad, with whom I had a slight acquaintance, sending me his compliments and announcing the resumption of his practice. Surely such thick skinnedness and lack of all decent feeling is not prejudicial in their favor.

Harold Barclay, M.D., New York.

[Comment.—For over a year the Medical Research Committee of Great Britain has been printing in the Medical Supplement to the "Review of the Foreign Press" abstracts of German, Austrian and other periodical medical literature. Their action, similar to that of The Journal in abstracting this literature, is recognition of the aphorism which forms the caption to this series of letters "It is proper to learn even from the enemy."—Ed.]

NEUROPSYCHIATRY

To the Editor:—I have read with much interest and value the address of the President of the American Medical Association delivered at the Atlantic City Session. The constructive values of preventive medicine have been vividly set forth therein, and the invaluable contributions of medicine as a determining factor in war, emphasized. But yet, I looked in vain for any mention of the work in neuropsychiatry of the American Army Medical Corps, as a feature in preventive medicine epoch marking in its historical value. Why is it that in reciting the work done in preventive medicine, in the A. E. F., omission is made of the remarkable work in neuropsychiatry? Why is it that in the Allied Health Conference, held in April "overseas," neuropsychiatry failed in being represented? Why is it that cognizance is not taken of the "man power" potentials vested in prevention, by elimination through the Division of Neurology and Psychiatry of the undesirables from the army, and of equal importance, the intelligent handling of desirables in so-called "shell shock" cases, at the front, during the combat period, as being a contribution in preventive medicine worthy of mention?

American psychiatry (by the term "psychiatry" is included all manner and form of mental disorders) made for itself a place in the history of medicine during America's participation in the great war and I, for one, want to see recognition given to this fact in such addresses as that of the President of the American Medical Association.

Frank P. Norbury, Springfield, Ill.

ONE CAUSE OF OCULAR DISCOMFORT AT THE "MOVIES"

To the Editor:—Ordinarily the vertical image on the screen is seen by both eyes, with optical axes in a plane at right angles to the vertical plane of the screen. This is the case when an unobstructed view of the screen is to be had. But many times, the view is obstructed by an intervening spectator and one tilts the head to one side or the other in order that both eyes may be used or that the screen may be seen at all. This changes the relationship of the plane of the screen and the plane of the optical axes from a right angle to an acute angle. The result of this change in angle is to throw the image on to other and unaccustomed portions of the retina. The consequence of this change is the unconscious endeavor to return the plane of the optical axes of the eyes to the right-angled relationship with the vertical plane of the screen. This endeavor manifests itself by the excessive innervation of the muscles of rotation of the eyeballs, resulting in muscular tiring or ocular discomfort.

The remedy lies in an unobstructed view of the screen and a continued vertical position of the head. The ideal moving picture theater should, therefore, have a marked pitch to the floor so that each spectator will have an unobstructed view of the screen over the head of the spectator seated directly in front. In lieu of this, a careful alternate spacing of seats will provide the necessary unobstructed line of vision.

H. S. Gradle, M.D., Chicago.

West Virginia: Huntington, July 8-10. Sec., Dr. S. L. Jepson, Masonic Bldg., Charleston.

CONSOLIDATION LAW IN IDAHO

The following emergency laws have recently been passed in Idaho placing the licensing of those engaged in registrable professions, trades and occupations under the control of a department of law enforcement. This legislation is patterned after the Illinois Civil Administrative Act. It does not change the requirements for physicians in that state but provides that all clerical work and enforcing of the law shall devolve on the new department. The department is in charge of a commissioner, Mr. Robert O. Jones, and a director, Mr. Paul Davis. The law is as follows:

EMERGENCY LAWS, ARTICLE III

Sec. 31. *Department of Law Enforcement.*—The Department of Law Enforcement shall have power: To exercise the rights, powers and duties vested by law in the State Board of Medical Examiners, its president, secretary and treasurer.

Sec. 32. *Same: Registration of Occupations.*—The Department of Law Enforcement shall, wherever the several laws regulating professions, trades and occupations which are devolved upon the department for administration so require, exercise, in its name, but subject to the provisions of this act, the following powers:

1. To conduct examinations to ascertain the qualifications and fitness of applicants to exercise the profession, trade or occupation for which an examination is held; to pass upon the qualifications of applicants for reciprocal licenses, certificates and authorities.
2. To prescribe rules and regulations for a fair and wholly impartial method of examination of candidates to exercise the respective professions, trades or occupations.
3. To prescribe rules and regulations defining, for the respective professions, trades and occupations, what shall constitute a school, college or university, or department of a university, or other institution, reputable and in good standing, and to determine the reputability and good standing of a school, college or university, or department of a university, or other institution, by reference to a compliance with such rules and regulations.
4. To establish a standard of preliminary education deemed requisite to admission to a school, college, or university, and to require satisfactory proof of the enforcement of such standard by schools, colleges and universities.
5. To conduct hearings on proceedings to revoke or refuse renewal of licenses, certificates or authorities of persons exercising the respective professions, trades or occupations, and to revoke or refuse to renew such licenses, certificates or authorities.
6. To formulate rules and regulations when required in any act to be administered.

None of the above enumerated functions and duties shall be exercised by the Department of Law Enforcement, except upon the action and report in writing of persons designated from time to time by the commissioner of law enforcement to take such action and to make such report, for the respective professions, trades, and occupations as follows:

For the medical practitioners six persons, all of whom shall be graduates of reputable medical colleges or universities and reputable physicians licensed to practice medicine and surgery in this state, a majority of whom shall not be representative of any one school of medicine and among whom three schools of medicine shall be represented.

DEGREES IN PUBLIC HEALTH

Measures for standardizing the various degrees and certificates offered in the public health service have been considered recently at a meeting held at Yale University. Representatives of Johns Hopkins University, the Massachusetts Institute of Technology, Harvard University, New York University, and the University of Pennsylvania attended the conference. A recent issue of *Science* has published the following resolutions which were adopted at the meeting.

1. That the degree of Doctor of Public Health (for which the abbreviations should be Dr.P.H.) for graduates in medicine should normally be awarded after two years of work done under academic direction, of which one year at least should be residence; and that the requirements for the degree should include class work, practical field work, and an essay based on individual study of a particular problem.
2. That the degree of Doctor of Philosophy or Doctor of Science in Public Health or Hygiene should be conferred on students who hold the bachelor's degree from a college or technical school of recognized standing, and have satisfactorily completed not less than three years of graduate study. It is understood that this degree is based upon the fundamental sciences associated with hygiene and public health, including a knowledge of physics, chemistry, general biology, anatomy, physiology, physiological chemistry, pathology, and bacteriology, in addition to the thesis and other usual requirements for the Ph.D. and Sc.D. degree.
3. That the certificate in Public Health should be granted for not less than one academic year of work to those who have received a bacheolor's degree from a recognized college or technical school or have satisfactorily completed two years of work in a recognized medical school, provided they have previously pursued satisfactory courses in physics, chemistry, general biology and general bacteriology.
4. That the degree of Bachelor of Science in Public Health or Hygiene should be given for the completion of a four years' course, the last two years of which have been devoted to the fundamental sciences associated with hygiene and public health.
5. That the authorities having the appointment of health officials be urged to give preference as far as possible to persons holding degrees or certificates in public health or hygiene.

Connecticut March Examination

Dr. Edwin C. M. Hall, secretary of the Connecticut Homeopathic Medical Examining Board, reports the written examination held at New Haven, March 11, 1919. The examination covered 7 subjects and included 70 questions. An average of 75 per cent. was required to pass. One candidate was examined and passed. Three candidates were licensed on credentials. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
New York Homeopathic Medical College	(1912)	80.3

LICENSED BY ENDORSEMENT OF CREDENTIALS

College	Year Grad.	Certificate from
University of Iowa, Coll. of Homeo. Med. (1893) *;	(1910)	Iowa
Boston University	(1915)	R. Island

* Registered under the amendment to the Connecticut medical practice law, which provides that physicians who graduated prior to May 25, 1892, may claim registration without examination.

Medicolegal

Trying to Force Wassermann Test on Suspected Person

(Wragg v. Griffin, Sheriff, et al. (Iowa), 170 N. W. R. 400)

The Supreme Court of Iowa sustains a writ of habeas corpus, and orders the release of the petitioner therefor, in this case wherein the court says that the question presented may, in its final analysis, be stated as being:

> May the local board of health of the city of Des Moines, on suspicion that the petitioner is afflicted with a venereal disease, or has been exposed to such contagion, lawfully order him under arrest and subject him by force to an examination of his person and compel him against his will to permit a quantity of blood to be extracted from his veins, and then be held in continued durance until the blood has been sent to an expert in a distant city and by test therof it is determined whether such petitioner is or is not in fact so diseased?

After having examined with some care the various statutory provisions and board of health rules to which its attention was called, the court is forced to the conclusion that the power is nowhere provided either expressly or by necessary implication. While the statutes in terms authorize boards of health and health officers to deal with quarantinable diseases, there is no express provision for interfering with the liberty of persons who are merely "suspected" of being diseased. Special emphasis was placed on that part of the rules of the state board of health wherein it is made the duty of the mayor to direct the chief of police to cause persons suspected of being diseased "to be investigated," and authorizing health officers in such cases "to make examinations" of suspected persons and to detain them as long as it may be necessary to determine whether they are so afflicted. But even here there is an entire absence of any express authority to subject a suspected person to an examination by physical force or by an extraction of blood from his body by violence for experimental purposes. Men and women were examined and treated by physicians for sexual diseases for generations before the so-called "Wassermann test" was discovered or invented, and, so far as this court is informed, with reasonably reliable results. At least there was no evidence here that, even in the technical phrase of physicians, the word "examination" in such cases is understood as necessarily meaning a blood test by the Wassermann method, or by any other method involving violation of the person, and, in the absence of explicit authority for the subjection of a person to such treatment on suspicion alone, it ought not to be approved as a valid exercise of authority.

This petitioner may be a bad man, but the court has no right to assume such a fact for the purpose of minimizing his claim to protection of the ordinary rights of person which law and the usages of civilized life regard as sacred until lost or forfeited by due conviction of crime. Even when charged with the gravest of crimes, he cannot be compelled to give evidence against himself, nor can the state compel him to submit to a medical or surgical examination, the result of which may tend to convict him of a public offense, and, if there be any good reason why the same objections are not available in a proceeding which may subject him to ignominious restraint and public ostracism, it is at least a safe and salutary proposition to hold that, before the courts will uphold such an exercise of power, it must be authorized by a clear and definite expression of the legislative will. This the court does not have, and in its judgment the restraint of the petitioner, not as a diseased person whose detention in a separate house or hospital the statute authorizes, but solely as a suspect and for the avowed purpose of forcing the exposure of his body to visual examination and compelling the extraction of blood from his veins in search of evidence of a loathsome disease which may or may not exist, is a deprivation of his liberty without due process of law, and he is entitled to be set free.

Vaccination Versus Personal Rights and School Law

(City of New Braunfels et al. v. Waldschmidt et al. (Texas), 207 S. W. R. 303)

The Supreme Court of Texas reverses a judgment of the court of civil appeals, which (193 S. W. 1077) reversed a judgment of a lower court in favor of the defendants in this suit wherein the plaintiffs, Waldschmidt and others, attacked the validity of an ordinance adopted by the city council of the city of New Braunfels, providing that no person should be permitted to attend the public or private schools within that city, without presenting a physician's certificate to the person's vaccination within six years, and providing for the punishment, by fine, of any one on conviction of sending a child to any school within the city who had not been vaccinated, or on conviction of admitting a child into such school without a certificate of vaccination. The court says that the contention that this ordinance was inconsistent with the liberty guaranteed by the federal and state constitutions was too completely repelled by the opinion of the Supreme Court of the United States in *Jacobson* v. *Massachusetts*, 197 U. S. 22, 25 Sup. Ct. 358, to justify discussion.

If the plaintiffs, or any of them, had a right with respect to the children's school attendance, which could properly be considered a property right, this was held subject to a valid exercise of the police power of the state. Nor did the ordinance in any way undertake to control or interfere with any rights of conscience in matters of religion. Section 6 of the bill of rights in the state constitution does not relieve one from obedience to reasonable health regulations, enacted under the police power of the state, because such regulations happen not to conform to one's religious belief.

In the court's opinion, this ordinance was no more than a regulation deemed necessary and expedient by the city council to suppress the disease of smallpox in New Braunfels, and to promote the health of all the people of the city, and hence plainly within the scope of the power granted to the council, on which the state statute expressly conferred the power "to do all acts and make all regulations which may be necessary or expedient for the promotion of health or the suppression of disease." The court cannot assent to the proposition that with smallpox still in New Braunfels, and in other nearby communities, with which commercial and social intercourse was continuous, the trial court would have been warranted in declaring the ordinance unreasonable, having for its object to protect as far as practicable, by means of vaccination, the health and lives of the children and all the people of that community.

There was no conflict between this ordinance and the Texas law for compulsory education, for that law expressly exempts from its requirements "any child whose bodily . . . condition is such as to render attendance inadvisable." Certainly an unvaccinated child would come within that classification when those charged with the duty to protect the public health in his community had declared that before he could be considered bodily fit to attend school he must be vaccinated. The effect of the court's conclusions is not to impose compulsory vaccination on the minor plaintiffs, nor to subject their parent to prosecution if he withdraws them from school, because of his opposition to vaccination. It is simply to deny these minors the privileges of the schools until they comply with the ordinance passed for their own protection and for the protection of their families, along with all others residing in the community.

Must Have Prior Written Order for Services

(Lacy v. Monona County (Iowa), 169 N. W. R. 760)

The Supreme Court of Iowa affirms a judgment for the defendant county, in this action brought by a physician to recover for professional services rendered and medicine furnished to certain persons who were afflicted with smallpox and who were in quarantine; because there was no written evidence that the local board of health had determined the need of the services or had appointed the plaintiff to render them. The court says that the plaintiff was health officer, appointed by the township trustees. The services were rendered at the oral request of the township clerk and the board of trustees of the township, acting as a board of health. The bill as presented by the plaintiff to the board of supervisors, and the bill on which this suit was predicated, complied with all the requirements of the statute (Section 2571a of the Supplement of the Code of 1913), except that there was no written order designating the plaintiff as the person to furnish the services before the services were actually furnished, and no such order was attached to the bill or account when it was presented to the local board for audit and payment.

The statute does not directly say that bills shall not be allowed unless this order is attached; yet it is apparent that, in order to avoid frauds and impositions on the people of the county, the provision was made that, at the time bills for this kind of services were presented for audit and payment, there should be a written order, from either the board of health or its clerk, acting under proper regulations of the board, evidencing the fact that, before the services were rendered, the attention of the board was called to the fact of the need of the services, and that the board, in writing, ordered and directed the services to be rendered. It is no hardship to require one who seeks to hold another for services rendered, for which the one sought to be charged is only secondarily liable, to show that the authority to do the act was given him, in writing, by the body by whose authority it is sought to bind the party charged. So the rule is not unresonable, nor is it a harsh rule. It might in this particular instance work a hardship, but the rule is made for the protection of the public, and is general in its application, and is mandatory in its character, and therefore the fact that it works a hardship in an individual case does not deprive the rule of its efficacious qualities, or make it an unjust or unreasonable rule in its general application.

The facts on which the plaintiff relied were simply these: He was a practicing physician. He was appointed health officer under the local board of health, under the provisions of Section 2568 of the Code of 1897. But this health officer's fees or compensation are fixed by the local board. His duties do not require him to render services to the sick. His duties are to assist the board in discharging those duties which the law imposes on the board. There is nothing in this statute that extends to him the right to administer to the sick of the township at the expense of the county. When he renders services to those afflicted with contagious diseases, he is governed, like any other physician, by the provisions of Section 2571a. The liability of the county is purely statutory; and to render the county liable the requirements of the statute must be observed. The township boards of health, so far as they act in the matter, bind the county only by the observance of those conditions prerequisite to creating an obligation on the part of the county. Nor was it incumbent on the board of supervisors to inform him of the fact that he had not complied with the law, because that fact was well known to him, and, even, if it had informed him at the time it rejected his bill, he could not have remedied the fact by procuring an order at that time.

Loss of Eye Greater Than Loss of Sight

(Nelson v. Kentucky River Stone & Sand Co. (Ky.), 206 S. W. R. 473)

The Court of Appeals of Kentucky reverses a judgment that affirmed an award of the workmen's compensation board for the loss of an eyeball the same as for the loss of the sight of an eye. The court says that it must consider the case in the light of the board's finding that the man's eyeball was removed and he was compelled to wear a glass eye, but that neither of these things impaired his earning capacity beyond the loss of the sight of his eye, or caused a disfigurement that impaired his future usefulness or occupational opportunities. The question therefore was whether the award conformed to the Workmen's Compensation Act, and this depended on whether the injury fell within the specific schedule providing compensation for the loss of the sight of an eye, or under the general provision applying to all other cases. In this connection, it must be borne in mind that disfigurement impairing the future usefulness or occupational opportunities of the injured employee is not an indispensable condition to compensation under the general provision, since that provision applies "in all cases of permanent partial disability, including any disfigurement," etc. Hence the adverse finding of the board on this phase of the question was not controlling. Looking at the Kentucky act, we find that it provides compensation at a certain rate for "the loss of a thumb," the "loss of a first finger," the "loss of a hand," the "loss of an arm," etc., thus showing that the compensation therein provided for was confined to the loss of the particular member named. When it deals with the eye, however, it does not provide for compensation for the loss of the eye itself, but solely for the "loss of the sight of an eye." If it be true, and there is no reason to doubt the soundness of the rule, that the purpose of the legislature was to confine the fixed compensation provided for specific injuries to those injuries and no others, and that the compensation allowed for a specific injury was not payable for a less injury, the rule should work both ways, and the compensation provided for a particular injury should not be held to include a greater injury. Here, the employee lost, not only the sight of his eye, but the eye itself. His injury therefore was greater than the mere loss of the sight of the eye. That being true, his case did not fall within the schedule making compensation solely for the loss of the sight of an eye, but fell within the general provision awarding compensation "in all other cases of permanent partial disability," etc.

Proof Required in Case of Blood Test

(Hershiser v. Chicago, B. & Q. R. Co. (Neb.), 170 N. W. R. 177)

The Supreme Court of Nebraska holds that where it is sought to prove the result of a blood test, the testimony should negative the possibility of any interference with, or substitution of other blood for, the object of the test. The court says that this was an action for personal injuries alleged to have been caused by the detention of the plaintiff in a freight car whereby he became chilled and suffered a nervous shock and other injuries. A medical witness testified that the plaintiff was suffering from locomotor ataxia. Realizing that this condition might have resulted from a constitutional disease, the plaintiff had procured the Wassermann test for the presence of syphilis to be applied to a quantity of his blood drawn for the purpose of the test. It appeared from the evidence of the physician making the test that the blood, from the time it was drawn until the time the test was applied, was in the ice box of the laboratory, and that others besides himself had access to the laboratory, and that it would have been possible to have substituted another sample for the plaintiff's blood. On redirect examination the witness testified that the only persons who had access to the blood were men associated with him in his office, that he made no change in the blood himself, and that no one in his office did so to his knowledge. The defendent moved to strike out the testimony as to the test, for the reason that the possibility of a substitution of blood was not precluded by the facts shown. The motion was overruled, and this was assigned as erroneous. As a general rule, the probability of any tampering with the objects of such tests should be negatived before evidence of this nature is admitted. The only persons who had access to the laboratory were those associated with the physician. It would have been better to prove that the bottle and its contents had been absolutely undisturbed by ony one except the witness; but since another blood test was made under proper conditions, with the same result, under the circumstances it was not prejudicial error to retain this testimony.

City Not Liable for Negligence of Nurse in Hospital

(Browder et al. v. City of Henderson (Ky.), 207 S. W. R. 479)

The Court of Appeals of Kentucky affirms a judgment in favor of the defendant, which was sued for damages for the burning, with a hot water jug, by the alleged negligence of a nurse, of Mrs. Browder while she was a patient in the city hospital. The court says that it is committed to the rule that in the performance of public or governmental duties a municipal corporation cannot be made to respond in damages for the negligent acts of its employees, which, however, does not release the individual whose negligence has produced an injury from a suit at the instance of the person injured. Among its statutory powers, the defendant is given the right "to establish and erect hospitals," etc. In the management of its hospital the city is performing a governmental function just as much as in the operation of its city hall elevator, city prison, etc. Moreover, this court and other courts have held that the mere fact that the city may receive some pay or remuneration in the operation or maintenance of its public institutions does not take the case out of the general rule. And it is held here that the mere fact that some of the patients in the hospital were pay patients did not alter the rule, and the city could not be held for damages in this action.

Cannot Take Ethical Standing to Discredit Skill

(Washington & Old Dominion Ry. v. Warner (Va.), 97 S. E. R. 799)

The Supreme Court of Appeals of Virginia holds, in this personal injury case, that there was no error in a refusal of the trial court to admit evidence tending to disparage the professional standing of the physician who attended the plaintiff when injured, and, incidentally, to affect the reliability of his testimony. The supreme court of appeals says that the trial court refused to permit the witness to be examined as to the reasons why he was denied membership in the medical association of the city of Washington, and also excluded the evidence of a medical witness concerning his standing in the profession. The physician in question was a graduate of Georgetown University, and had practiced medicine about ten years; and the proposed attack was aimed rather at his ethical standing than his professional skill. A person may be a competent physician and yet disregardful of professional proprieties.

Society Proceedings

MISSOURI STATE MEDICAL ASSOCIATION

Sixty-Second Annual Meeting, held at Excelsior Springs, May 26-28, 1919

The President, Dr. M. P. Overholser, Harrisonville, in the Chair

Management of Streptococcic Empyema

Dr. H. P. Kuhn, Kansas City: The recent epidemic of influenza has given an opportunity for the study and observation of a large number of empyema and lung abscess cases under treatment in U. S. Army base hospitals. Each case eserves an intelligent, individual treatment depending on he pathologic condition, type of organism and constitutional condition.

Mechanics of Fluid in Pleural Cavity

Dr. Logan Clendening, Kansas City: There are six forms of fluid occurring in the pleural cavity. Much confusion has arisen owing to the fact that the distinction between free and fixed fluids has not been made sufficiently clear in either the textbooks or current literature. The diagnostic signs of fluid in the pleural cavity have usually been given as bulging intercostal spaces, dulness on percussion, shifting with change of position, absence of vocal fremitus and breath sounds over the fluid, displacement of the heart, the S shaped curve of Ellis and Grocco's sign. In pleural effusion and empyema the fluid does not usually change on change of position owing to the fact that these fluids are inflammatory in nature and cause adhesions between the visceral and parietal pleura, just as inflammatory fluids in the abdomen cause adhesions and are fixed by them. Breath sounds, râles and sometimes bronchial breathing are not infrequently heard over fixed fluids. Bronchial breathing is heard when the effusion is sufficiently large to press against a primary ronchus. However, the bronchial breathing is usually disant. The fact that in pleural effusion a comparatively large rea of dulness may yield on tapping on a small quantity f fluid can be explained on the basis of a thin layer of uid held in place by adhesions over a large area of chest. he irregularities of the outline of the adhesions holding up a pleural effusion or empyema helps to explain the failure of diagnostic tapping to reveal the presence of fluid. These facts are proved by the use of the roentgen ray and by careful postmortem examination.

DISCUSSION OF PAPERS BY DRS. KUHN AND CLENDENING

Dr. Hudson Talbott, St. Louis: Symptoms of fluid in the chest cavity arise principally through the compression and displacement of the organs. The sick side is usually considerably larger than the well side, although that may not always be noticed. The use of the cytometer helps, also the use of the lead strip to conform to the chest wall.

Dr. J. C. Lyter, St. Louis: Erdmann, at Camp Custer, was one of the first not to operate too early in empyema and not to operate in any case of pneumococcic empyema until the pneumonia had entirely cleared up. Especially should we consider the condition of the opposite lung because with the pneumonia not entirely cleared up, when the pus is removed from the opposite chest, the lung that had no empyema goes into a state of compensatory emphysema and the patient dies. As to the shifting of fluid in the chest, I agree with Dunham of Cincinnati that the only two fluids we see shift are the fluid that accompanies carcinoma and the fluid that has air with it.

Dr. N. I. Stebbins, Clinton: If we have more than one pus cavity we must treat each one separately. I have found it very successful to take an ordinary sized drainage tube, put a piece of rubber tissue in the palm of the hand, make a hole through the tissue about one-quarter the size of the drainage tube, and then by careful manipulation drawing the drainage tube through the tissue, which necessarily draws the rubber tisue up alongside of the tube and parallel with the tube. Then having made the resection, the tube is placed in the cavity.

Dr. Llewellyn Sale, St. Louis: Our experience was that a large number of cases went on to uneventful death—except that there had been some surgery done. In a number of these empyemas where we drained we found abscesses, collections of pus along the vertebral column, that were absolutely inaccessible irrespective of any method that might have been proposed under the present status of surgery. This makes us realize how helpless we are in the face of this overwhelming infection.

As for late operation, Dr. Lyter put his finger on the pulse of this problem. All of us, it seems, now favor late operation in empyema, but I would like to sound a note of warning, not for the purpose of differing with those who advocate late operation but that we may be able to use the lessons we have learned in this late experience. We must remember that cases operated on early during the empyema period of the disease came early in the epidemic of 1917. They were those fulminating, overwhelming infections from which the patient died in twenty-four to forty-eight hours, and from which the patient would have died and did die whether he was operated on or not. Statistics show a mortality of 50, 75 to 90 per cent. Then new methods were proposed, among them late operation, and then the reports began to get better, the mortality began to go down. Certainly part of the explanation is that the virulence of the infection began to subside, or that the individuals were able to build up a stronger resistance. I believe late operation is the safer step. As to movement of fluid in the chest, of course the main movement of fluid is that combined with air. In chylothorax the fluid changes just as rapidly as the pneumothorax, the level of the fluid being always horizontal, no matter what position. We thought that was due to the high percentage of fat in the exudate.

Neuroretinitis (Choked Disk) Sequel to Thyroid Extirpation

Dr. J. W. Sherer, Kansas City: A woman, aged 32, suffered severely with exophthalmic goiter. The thyroid gland was removed five years ago with complete recovery from all symptoms. For about five months she has been suffering severe asthenopic symptoms and during the last two months exophthalmos with swelling of the eyelids has developed. Pain through the left eye and the left side of the head is very severe. The fundus reveals the classic picture of neuroretinitis or choked disk. No hemorrhages occurred. Urinalysis and Wassermann are negative. The patient is nervous and emotional. The left eye has become totally blind during the last five days. The patient was put to bed on a restricted diet with bromids and alteratives. Pilocarpin sweats were given regularly. Complete recovery ensued in two months. Exophthalmos and choked disk disappeared.

DISCUSSION

Dr. E. H. Higbee, St. Louis: I do not think that this was a case of exophthalmic goiter. A negative Wassermann does not mean that the patient does not have syphilis. The fact that the patient was highly nervous can easily be explained in that she realized she had a serious eye trouble and had previously suffered from exophthalmic goiter. The quick recovery from such severe symptoms under potassium iodid and diaphoresis leads me to believe that this was not a sequel of thyroid trouble, but a gumma of the orbit.

Dr. J. W. Scherer: The patient did not have any treatment that could have cured her if this had been a neuritis of syphilitic origin. She had 1/100 grain of mercuric chlorid three times a day, for the first week only, and 5 grains of potassium iodid three times a day for three weeks. She got bromids for nervousness and sweats, regulation of diet and rest in bed and the inflammatory process in the optic nerve subsided.

Plea for the Early Recognition of Stomach Malignancies

Dr. E. H. Kessler, St. Louis: Some writers claim that 50 per cent. of cancers in the human race are situated in the stomach. The early symptoms of cancer may be those of an ordinary dyspepsia, but when these symptoms persist after a corrective diet the patient should be examined critically. The methods of examination are the history, the physical findings, the laboratory, the roentgen ray and the exploratory incision. The roentgen ray will show filling defects in 95 per cent. of cases by the time the patient calls attention to his stomach. Negative findings in doubtful cases are of value in excluding cancer. The roentgen ray shows whether the case is operable.

Dr. O. H. McCandless, Kansas City: Since the advent of the roentgen ray the demonstration of this condition has been made possible and the percentage of gastric ulcer and cancer has lessened materially. Intrinsic and extrinsic growths are demonstrated with considerable accuracy. The stormy intestinal tract is seldom malignant unless it is an obstructive process.

Dr. C. H. Neilson, St. Louis: I wish to call attention to the pernicious habit of diagnosing everything as gastritis. I wish we could get away from that and back to the old idea of a good examination. We must use the roentgen ray in conjunction with everything else that is to be used. The stomach tube has fallen into disuse because they say it gives us no knowledge. But it does give us a lot of knowledge which by using intelligently and interpreting properly will aid us in diagnosing early cancer. Every man or woman over 40 whose stomach is disturbed should be considered as having cancer until proved otherwise.

Dr. Elsworth S. Smith, St. Louis: After we have availed ourselves of every aid to diagnosis, we are still faced with a doubtful situation, just as has been shown here unless we can differentiate between the filling defects of simple ulcer and the filling defects of malignancy. Therefore I want to made a plea for early operative interference—exploratory operation—in these cases.

Dr. J. G. Sheldon, Kansas City: We are getting more late cases of carcinoma now than fifteen years ago. There are several reasons, and one is the supreme confidence of the roentgenologist to diagnose carcinoma of the stomach. The second reason is that people are too often prone to neglect medical findings. The roentgen ray is only part of the examination, but carcinoma of the stomach is a progressive and permanent disease that does not improve in two or three months.

So long as you find men who are willing to treat a stomach condition as long as the patient will stand for it we shall continue to get more and more late cases.

Osteosarcoma

Dr. E. B. Knerr, Kansas City: Bone tumors may now be diagnosed and differentiated by roentgenograms. I had a case which did not respond to palliative measures and incision but was apparently checked by roentgen-ray treatment. Later there was lung involvement but the patient refused further treatment.

DISCUSSION

Dr. L. A. Marty, Kansas City: Bone sarcomas are supposed to follow some trauma, but just how the action of trauma is concerned in the matter we do not understand. The prognosis of sarcoma of the shaft of the bone is usually bad because subjects under 20 years withstand the progress of malignant tumors very poorly. The outlook is very dark indeed from this class of disease when surgery is considered alone.

If surgery is never sure and offers only possibly an extension of life for a very few months, we are entirely justified in trying some other method of treatment; among these might be mentioned the roentgen ray, radium, and possibly some heat treatment. A thing that I would like to see tried out thoroughly is the diathermic treatment of malignancies: that is, the treatment by electrical heat, generally spoken of as electrothermic coagulation. It has been shown perfectly by Percy in his treatment of carcinoma of the uterus by heat, that cancer cells are killed at a very low temperature: a temperature that will not affect normal tissue cells.

Dr. J. G. Sheldon, Kansas City: I do not believe that the roentgen-ray treatment alone in sarcomas of the extremities, where amputation can be done and the soft parts removed, is very beneficial. I believe that the combined treatment with steam and electricity is the treatment of the future.

So-Called Irritable Heart of Soldiers

Dr. J. C. Lyter, St. Louis: After studying the subject in the military camp at Camp Custer, Mich., I am convinced that this syndrome, which was first described by Da Costa during the Civil War and by the French, English and American physicians during the recent war, is not a cardiovascular disturbance primarily but the disturbance of the autonomic and sympathetic nervous system. This syndrome occurs most often in the "hypoplastic" class of patients. The syndrome is a nervous disturbance most probably having its origin in a psychic disturbance resulting from a conflict of desires. The hypoplastic individual, having an unstable nervous system, manifests the symptoms more pronouncedly than other classes of individuals.

Dr. M. A. Bliss, St. Louis: An internist in France insisted that all these cases were hyperthyroid, while I insisted that relatively few were hyperthyroid. They are constitutional cases. You cannot make soldiers out of these men. No form of treatment changed these individuals, either physically or mentally, so as to enable them to be good soldiers. The important point to recognize is that they are constitutionally inferior and are not capable of such restoration as would make them efficient men.

Dr. C. H. Neilson, St. Louis: When the first soldiers were being examined in St. Louis I went so far as to accuse some one of giving these young men thyroid extract. We put many of them into the army. Some came back with "neuritis," some with "hyperthyroidism" and some with "constitutional disorders." Later I decided to put these individuals into limited service but I found that the limited service men worked just as hard as the regular soldiers. So we decided to send them back to their own work. A study of these individuals from the standpoint of body configuration will show that they belong in one of the types I have mentioned. We do not know what is wrong with these people, or that there is anything wrong with them, but I believe there is something behind it. I am not so enthusiastic as to attribute all these disturbances to the ductless glands.

Why Prenatal Care?

Dr. C. A. Ritter, Kansas City: Antenatal supervision urges necessity of early obstetric registration of all candidates for motherhood. Until recently prenatal supervision was conspicuous by its absence. Gestation in the majority of present day women is not a complete physiologic process. Motherhood exacts a most severe test of woman's physical and nervous make-up. Educate the public by prenatal propaganda and antenatal clinics and remind the profession of the dangers of maternity. Contribute to the development of better maternity nursing; increase the demand for hospital accommodation at delivery; raise the standard of obstetric work ; render elective procedures more frequent and obstetric surgery more successful as a life saving agent.

Dr. D. R. Parman, St. Louis: If the child within the abdomen is dependent on the mother for its material growth, then it is reasonable to suppose that a healthy mother will produce a healthy child. A thorough physical examination should be made early—not only an obstetric examination but a physical examination—to determine the condition of the patient in general. In that way we are often able to elect a procedure that will materially lessen the loss of life of the mother as well as of the infant. In more than 2,600 cities in the United States prenatal clinics with visiting nurses have been established. The statistics from the Visiting Nurses' Association in Boston show that the death rate has been reduced from 4 to 2 per cent. New York reports similar statistics. In Paris, in 1915, of about 18,000 births, 74 per cent. occurred in hospitals, and the mothers were also furnished nurses that would visit them and give instruction. By conducting these prenatal clinics the mortality of the mother was reduced 20 per cent. and that of the children 30 per cent., notwithstanding the strain and unusual conditions brought about by the war.

Dr. G. C. Mosher, Kansas City: Prenatal care, if it is to be carried out ideally, must be given in connection with either a hospital or a prenatal clinic. It ought to be easy to educate the women to come at least once a month for examination of urine, blood pressure, etc., and routine examinations would give each woman a chance to have discovered any thyroid condition, anything wrong with the teeth, heart, etc. The Children's Bureau of the Department of Labor has a very simple routine: first, general physical examination; second, measurements; third, continued supervision; fourth, examination of urine, blood pressure, etc. New York has adopted this plan and a Wassermann test is made in every suspicious case.

Dr. E. P. Hamilton, Kansas City: The general physical examination of the patient is most important. The Woman's Municipal League of Boston has kept track of 5,000 cases for five years. In the first year they had sixty eclamptic cases; in the next four years, four. In four years they had no miscarriages and only six cases of premature labor; 87 per cent. of the mothers nursed their babies. Physicians who do not have hospital facilities can educate the women to come to them for examination, for as soon as they understand that you are trying to make labor easier they will come.

Rôle of Vasomotor Response in Cardiac and Renal Decompensation of Hypertensive Cardiovascular Renal Disease

Dr. Elsworth Smith, St. Louis: Hypertension is never conservative but always ultimately destructive to the heart. Hypertension should always be reduced when vasomotor response is retained, thereby conserving cardiac and renal compensation and improving or restoring decompensation in these organs. To be treated successfully, hypertension should be detected early before becoming refractory so as to prevent ultimate disaster to the cardiovascular renal apparatus.

DISCUSSION

Dr. Llewellyn Sale, St. Louis: The interesting point in Dr. Smith's presentation is to realize that his observations represent the swinging back of the pendulum. Not so many years ago high blood pressure was looked on as a mark to be shot at. Then came a time when we were advised to leave high blood pressure alone. Now Dr. Smith and his collaborators advise us to lower high blood pressure when we come in contact with it and in the manner described. The important thing is the underlying principle. We must attempt to fix in our own minds, even though we cannot do it very accurately, some plan by which these people can be put into a class where high blood pressure or hypertension is the thing that really needs attention.

Dr. Elsworth Smith, St. Louis: My rule is to lower the blood pressure every time I see a patient with hypertension.

Extracardiovascular Causes for Angina Pectoris

Dr. P. T. Bohan, Kansas City: Coronary scleroris and Allbutt's theory of aortitis are important etiologic factors in most cases. That spasm of normal coronaries may account for attacks is questionable. Experience indicates that such factors as heart strain, obesity and areas of irritation in the region of the fifth nerve, and possibly also in the abdomen, not only may aggravate an angina due to coronary or aortic disease, but also cause typical angina vera without organic changes in the heart or aorta. Abscessed teeth and diseased tonsils have been known to act as etiologic factors.

Dr. Elsworth Smith, St. Louis: The extraneous causes of angina pectoris cannot be accentuated too greatly. The condition must be present for the development of angina and reflex foci set off the explosion. While it is possible that our ideas of coronary disease may be exaggerated, I am not disposed to discredit these causes.

Decision Regarding Use of Common Towels.—The supreme court of appeals of Virginia has rendered a decision construing the laws of Virginia prohibiting the placing, keeping, or use of common towels in any public lavatory in a case in which the manager of an office building rented offices to different individuals, the lavatories on each floor being kept locked and each tenant having a key. In a prosecution for an alleged violation of the acts referred to the court decided in favor of the accused, holding that the lavatories were not public lavatories.—*Public Health Reports,* March 14, 1919.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

American Journal of Diseases of Children, Chicago

June, 1919, **17**, No. 6

*Influenzal Croup. J. C. Regan and C. Regan, Brooklyn.—p. 376.
Some Graphs and Tables Illustrating Growth of Human Stomach. R. E. Scammon, Minneapolis.—p. 395.
*Fat Metabolism of Infants and Young Children. II. Fat in Stools of Infants Fed on Modifications of Cow's Milk. L. E. Holt, A. M. Courtney and H. L. Fales, New York.—p. 423.
Infantile Scurvy Associated with Hereditary Syphilis; Report on Breast Fed Infant with Multiple Fractures. R. M. Greenthal, Ann Arbor.—p. 440.

Influenzal Croup.—A series of twenty cases, of which five terminated fatally, was studied by the Regans. The causative agent of this particular form of croup is not the diphtheria bacillus. The bacterial flora found was very similar to that noted in general among influenza cases. Thus in the nasopharynx cultures there was a predominance of the Pfeiffer bacillus, pneumococcus, and *Micrococcus catarrhalis.* In the cultures from the sputum streptopnuemococci and Pfeiffer bacilli were most common, with pneumococci and staphylococci in less numbers. In the treatment of the malady it was found usually best to administer diphtheria antitoxin, owing to the difficulty of making a definite differential diagnosis from laryngeal diphtheria. The treatment which proved exceedingly effective was the use of steam inhalations carried out in a small room in which the saturation of the atmosphere with vapor could be controlled carefully. The results were very satisfactory, and a number of intubations were thus avoided. In addition to steam inhalations, flaxseed poultices were applied to the neck; morphin sulphate and atropin sulphate were given in doses proportionate to the age, to control the spasms and the restlessness. Intubation was required in six patients, one being an adult. The immediate effect of the introduction of the tube in most instances was to make the patient worse, and extubation had to be performed immediately in three cases. The harmful effect seemed to be due to the fact that the pressure of the tube increased the congestion existing in the mucous membrane below, further adding to the mechanical obstruction. Antipneumococcus serum was used in one case with very beneficial effects. Diphtheria antitoxin seems to have no effect on the local process.

Fat Metabolism of Infants.—The material presented in this article comprises the results of analysis of 128 stools of seventy-seven infants, whose ages ranged from 2 to 18 months, fed on modifications of cow's milk. The average fat percentage of the dried weight in normal stools was 36.2. The hard, constipated stools showed no variation from this figure. In the stools not quite normal in appearance the average fat percentage was slightly lower. In severe diarrhea the fat percentage of dried weight was much higher, reaching an average of 40.7 per cent. The soap percentage of total fat was very high in both normal and constipated stools, averaging, respectively, 72.8 and 73.8 per cent. As the stools became less normal in appearance the soap fat diminished rapidly and averaged in the loose stools only 30.6 per cent. of the total fat, in the diarrheal stools 12.4 per cent. and in those of severe diarrhea only 8.8 per cent. of the total fat. The neutral fat was less than 10 per cent. of the total fat in normal and constipated stools. It increased as the soap fat diminished and in diarrheal conditions made up about 60 per cent. of the total fat in the stool. The free fatty acids constituted about 17 per cent. of the total fat of normal and of constipated stools. It was increased somewhat as the stools became less like the normal and in the diarrheal stools was over 30 per cent. of the total fat of the stool. No definite relationship was shown between the daily fat intake and the percentage of fat or the distribution of fat in the stool. The average percentage of the fat retained with normal stools was 91.3 of the intake. The retention was but little lower when the stools were somewhat harder or softer than normal, or were not homogeneous, or contained more or less mucus without being distinctly watery. As the water in the stools increased, the percentage of retention dropped markedly, reaching in severe diarrhea 85.4 per cent. of the intake. There was no striking relation between the fat intake and the percentage of the intake retained, except when the intake was abnormally low.

Fracture of Femur.—This paper analizes statistically 131 consecutive cases of fracture of the femur treated in the American Red Cross Military Hospital No. 2 at Paris. A brief outline of the principles and methods of treatment is also given. Of the 131 cases, 26 patients died, a mortality rate of 19.8 per cent. With the exception of one acute gas gangrene flaring up after a sequestrectomy and death occurring in the eighth week, all the late deaths were due to the streptococcus. There was one late death from tetanus, but in this case a positive streptococcus blood culture was obtained and at necropsy multiple streptococcus foci were found. The authors urge that a compound fracture of the femur should be operated on and held for a month, or immediately transported without operation to a hospital where definite treatment can be carried out. The chief danger lies in infection, gas gangrene in the early weeks and streptococcus in the later weeks. Both can be best combated by early, adequate, and radical surgery. The primary operative procedure should be radical to the point of apparent brutality. Amputation should be done oftener and earlier. Bulkley and Sinclair convinced that if more care were paid to operative treatment, less would be heard of the chemical treatment of wounds. Such treatment should be unnecessary.

Pyloric Stenosis in Infancy.—Allen cites a case in which he operated when the baby was three months old. Instead of the usual tumor, he found a distinct plication at the pylorus, the duodenum bent forward and adherent to the stomach for a distance of almost a quarter of an inch. The area was hyperaemic and there were definite cobweb adhesions. Allen divided the adhesions with scissors, and straightened out the pylorus.

Precipitin Test for Blood in Feces.—According to Hektoen and his associates in this study the only conceivable practical value of precipitin tests for human blood proteins in feces would be in cases giving a negative result with a precipitin test and a positive Weber or benzidin reaction. Under these circumstances a negative result with the precipitin test would indicate that the positive chemical test probably was not due to the presence of human blood. Extracts of feces in salt solution often contain substances that form precipitate with antihuman serum. This seems to be the case just about as often in the case of healthy young men as of persons with various diseases. Such substances may be present in extracts of feces that do not give chemical tests for blood, and it may be inferred that such substances may be human proteins derived partly from the blood and partly also from the cells lining the intestinal tract. Extracts of feces of healthy men on unrestricted, full meat diet, only very exceptionally give positive reaction with antibeef, antisheep, antiswine and antichicken serums, showing that in health foreign proteins taken into the stomach as a rule do not reach the feces as such. In cases of pernicious anemia under treatment with arsenic the feces practically always give a positive reaction with antihuman serum.

Spirochete of Infectious Jaundice in Chicago Rats.—Spirochetes resembling those described as the cause of acute infectious jaundice were demonstrated by Otteraaen in only two Chicago house rats of thirty examined (or 6.6 per cent.), indicating that the spirochetes probably are not present in a high percentage of such rats. The spirochetes were demonstrated in material from the mouth and in tissue from the kidney. Because of the presence of spirochetes in the mouth of rats, Otteraaen suggests that it is possible that, at the time of the bite, organisms may be carried into the wound by the saliva or teeth, and disease in this manner transferred directly from the rat to man.

Pathologic Reflex of Great Toe.—Boveri cites ten cases in which in the absence of the Achilles reflex, percussion of the Achilles tendon provoked flexion of the second phalanx of the great toe. He claims that this reflex is never present in a healthy person nor when the Achilles tendon reflex is present. The persons in whom this reflex was elicited had lesions of the spinal cord, the spinal nerve roots or the sciatic nerve, most of them being the result of war wounds, especially of the sciatic nerve. The reflex is said to be absolutely diagnostic of a partial lesion of the cord, sciatic nerve or of the scatic external popliteal. The patient is placed in the prone position with the legs bent back to a right angle on the thighs so that the letter "Z" is formed. Then the Achilles tendon is struck with a reflex hammer, and the effect on the toe is noted.

Dispensary and Psychiatry.—An analysis of 140 patients suffering from various psychoses was made by Osnato. They included cases of psychasthenia, late paranoid conditions, alcoholism and manic depressive insanity.

Extracardiovascular Causes for Angina Pectoris

[illegible] fore eight

DR. P. T. BOHAN, Kansas City: Coronary scleroris a[illegible] ich this Allbutt's theory of aortitis are important etiologic factors in[illegible] has most cases. That spasm of normal coronaries may account [illegible] the for attacks is questionable. Experience indicates that such factors as heart strain, obesity and areas of irritation in the region of the fifth nerve, and possibly also in the abdomen, not only may aggravate an angina due to coronary or aortic disease, but also cause typical angina vera without organic changes in the heart or aorta. Abscessed teeth and diseased tonsils have been known to act as etiologic factors.

DR. ELSWORTH SMITH, St. Louis: The extraneous causes of angina pectoris cannot be accentuated too greatly. The condition must be present for the development of angina and *reflex foci set off the explosion. While it is possible that our* ideas of coronary disease may be exaggerated, I am not disposed to discredit these causes.

Decision Regarding Use of Common Towels.—The supreme court of appeals of Virginia has rendered a decision construing the laws of Virginia prohibiting the placing, keeping, or use of common towels in any public lavatory in a case in which the manager of an office building rented offices to different individuals, the lavatories on each floor being kept locked and each tenant having a key. In a prosecution for an alleged violation of the acts referred to the court decided in favor of the accused, holding that the lavatories were not public lavatories.—*Public Health Reports,* March 14, 1919.

*Statistical Study of Prevalence of Intestinal Worms in Troops at Camp Zachary Taylor, Kentucky. B. Locke.—p. 621.

Intestinal Worms.—Over 15,000 soldiers were examined by Locke and others; of these 10,372 were white, 8,633 colored. All the white soldiers were residents of Kentucky; 6,948 colored soldiers came from Kentucky, 365 from Alabama, and 840 from Tennessee. Practically all were between 18 and 42 years of age and in good physical condition. It is emphasized that these men were soldiers in active service and presumably in good health. Therefore only men showing no appreciable signs of disease were examined. The parasites present were: hookworm (Necator americanus), roundworm (*Ascaris lumbricoides*), whipworm (*Trichuris trichiura*), dwarf tapeworm (Hymenolepis nana), beef tapeworm (*Taenia saginata*), Cochin-China worm (*Strongyloides stercoralis*). A marked difference in the frequency of infestation of white and negro soldiers was readily evident. Of the white soldiers 10.40 per cent. were infested; of the colored soldiers only 1.1 per cent. were infested. Two or more species of parasites in one person occurred 124 times. These concurrent infestations were only present among the whites.

Results of Surgical Treatment of Spinal Cord Tumors.—A series of sixteen cases in which laminectomies were *done* for spinal cord tumors is cited by Adson. The cases are said to represent fairly well the ratio of cord tumors to allied conditions, and the results accomplished by surgical treatment. Three patients recovered after the removal of the tumors, two have improved to such a degree that they are able to
In take up their regular work although there still *is some*

[illegible] as found. The

tumor was not removed on account of its extensive involvement in the cord itself; the patient has not improved. In the fifth case of nonremovable tumors, there was a definite history of syphilis nine years before with a development of a spastic paraplegia and a definite sensory level. A gumma of the cord involving the meninges was found. Again, results were unsatisfactory. In addition to the operations in the thirteen cases of spinal cord tumors, three cases in which the lesions were questionable were explored. A meningomyelitis, with increased cerebrospinal pressure was found. One patient did not improve, and gradually became worse; the second patient recovered and at present is doing his regular work, and the third died on the second day with a typical picture of fat embolism. This was the only death in the series.

Hemolytic Icterus: Splenectomy.—Schneider regards splenectomy as a cure for hemolytic icterus and urges that in all severe cases operation should be done. Gallstones, which complicate 60 per cent. of the cases, should be removed later.

Some Phases of New Children's Code of Interest to Physicians.—Of forty-one bills reported to the legislature by the Child Welfare Commission of Minnesota, thirty-five were enacted into law. These laws provided that mentally defective children may be committed through the probate court to the care and custody of the state board of control. This commitment may be by compulsion where necessary. All such commitments will receive attention by the board, either by institutional care for the most urgent cases, with special reference to girls and women of childbearing age, or by parole supervision in the community until institutional care can be provided. Physically defective children can be brought into the juvenile court when their parents will not secure proper medical attention for them. All maternity hospitals are licensed by the state board of control in addition to whatever regulation is provided by the board of health. All births in maternity hospitals must be reported to the board of control in addition to the board of health, and a statement must be made as to legitimacy. Rights and duties in a child can only be transferred by order or decree of court, usually the juvenile court. Fathers of illegitimate children should be made fully responsible, and mothers must nurse their babies while under the control of the hospital and as long thereafter as is possible and necessary.

War Contractures—Localized Tetanus, Reflex Disorder or Hysteria. A. F. Hurst.—p. 579.

Restoration of Urethra.—In Adam's case an artificial urethra was constructed by sewing a piece of Baer's membrane around a catheter.

Digestion of Esophagus.—The histories of fifteen cases encountered at the postmortem examination and in which it is considered most probable that digestion of the esophagus occurred during life, are cited by Pringle and Teacher. In eleven of these there was vomiting of brown or black material, or actual hematemesis. In eight cases the condition in the esophagus was advanced—destruction and perforation; in seven it was early. In eight there was no digestion of the stomach. In seven there was slight digestion of the stomach. In nine there had been operations, and in the six cases in which there had not been any operation there were similar changes in the esophagus. The vomiting of black material or actual hematemesis was observed in eleven out of the fifteen cases.

Suppurative Arthritis of Knee.—The "physiologic method," is the term applied by Everidge to this treatment, for the natural processes of repair enter largely into its rationale. It relies for its curative effect on active movements of the joints of the lower extremity, including the knee. It is emphasized, however, that adequate openings in the infected joint must first have been established to allow the free escape of synovia and pus; otherwise, movement will result in the dissemination of sepsis into culdesacs of the joint and extra-articular muscle planes. Active movement of the joint is begun soon after it has been operated on, and is regulated by the surgeon. In about 50 per cent. of the cases treated a useful mobile joint has been obtained. In the absence of extensive bone injury—which necessarily negatives this treatment—provided the physiologic method is established early, resolution is hastened and tracking is rare. Collections of pus in the popliteal space occur frequently. The method is impracticable if its adoption be delayed until the establishment of the fulminating stage of suppurative arthritis.

Modified Open Ether Anesthesia.—Silk uses a mixture consisting of 1 dram of chloroform and 32 drams of ether. The patient should have a preliminary injection of morphin (1/6 to 1/4 grain) and atropin (1/100 to 1/60 grain). The face pad and mask is the same as for open ether, the mask being closely applied to the face and face pad from the very beginning. The liquid is used exactly as if it consisted of ether alone, the presence of the small quantity of chloroform being ignored. During induction the liquid is poured freely onto the mask just to the verge of resentment, but when consciousness and reflexes are abolished, it will suffice to reduce the supply to the dropping stage. The combination has given excellent results.

Treatment of Eczema by Rectal Saline Injections.—Spurgin reports a case of eczema in which a rectal saline enema containing 1 ounce of whisky was given every other day, after clearing the bowel with soap enema. The patient was apparently past all help when this form of treatment was commenced, and the really extraordinary change which took place in a few days, Spurgin says, was interesting and gratifying.

Unusual Case of Hemorrhage from Tonsillectomy.—In Whale's case profuse bleeding occurred from an aomalous tonsillar branch from the internal carotid.

*Case of Intussusception Treated by Resection. E. R. Flint.—p. 938.

*Improved Method for Estimation of Sugar in Urine and Blood. P. J. Cammidge.—p. 939.

Sympathetic Nervous System in Glycosuria.—The following classification of persistent glycosuria is suggested by Brown: 1. Organic origin, with structural changes in the endocrine glands leading to (*a*) overaction of suprarenal, thyroid, pituitary or (*b*) underaction of pancreas. 2. Sympathetic origin, with no evidence of structural changes in any endocrine gland, but producing a functional (*a*) overaction of suprarenal, thyroid, pituitary and (*b*) underaction of pancreas. This really makes spontaneous diabetes a disease of the sympathetic nervous system. Brown believes that diabetes is due to deficiency of the pancreatic amboceptor, which deficiency may be due to structural changes in the pancreas or to inhibitory action of the sympathetic on its internal secretion; this effect may be aggravated by sympathetic stimulation of other endocrine glands, thus further diminishing the power of carbohydrate assimilation.

Chronic Colopathies.—In a series of 102 consecutive cases of chronic colitis Joltrain et al. have been able to collect 73 cases in which the existence of an initial acute stage appears evident. Chronic colopathies appear in numerous cases to follow an acute dysentery (27 cases) or an acute dysenteriform colitis. It is classical that amebic dysentery often (38 cases) brings with it as sequel a chronic colopathy. The same trouble can be seen after dysentery caused by *B. shiga* (3 cases), a fact hardly noted up to the present. More rarely these chronic colopathies are consecutive to some other infection or intoxication (18 cases) which has caused a primary acute inflammation of the large intestine.

Case of Intussusception Treated by Resection.—Flint's patient was aged one day less than three months. He believes that this is the youngest case on record in which recovery took place. The ileum (4 or 5 inches of it) had slipped up into the cecum and colon. This portion of the ileum was removed in the usual way.

Improved Method for Estimation of Sugar in Urine and Blood.—Cammidge advises that when a urine is expected to contain a low percentage of sugar, under 0.5 per cent., and with all blood and other fluids containing smaller amounts, the water to which the iodin solution is to be added should be boiled thoroughly to expel dissolved air and cooled immediately before the estimation is to be made. It is also advisable that the alkaline copper solution for sugar estimations with urine should be boiled in a small conical flask provided with a loose funnel as a stopper instead of in a beaker, and that the required amount of urine should be run into the boiling fluid from a pipet when the air dissolved in the solution and contained in the flask has been expelled. With blood, etc., the 7.5 c.c. of filtrate and 1 c.c. of sodium carbonate solution are boiled together in a similar way in a small conical flask fitted with a funnel-stopper, and the 1 c.c. of modified Benedict solution is added after they have boiled for a few seconds. The water used for diluting the iodin solution and for washing out the flask, etc., should have been recently boiled and cooled. With these additional precautions the method gives uniformly reliable figures, even with the small amount of sugar in normal urine and blood.

*Measurement of Depth of Roentgen Shadows. M. de Abreu.—p. 608.

Calcareous Concretions in Lungs Simulating Fragments of Shells. Infroit.—p. 610.

Cesarean Section.—Bar has a record of 275 conservative cesarean sections done by himself or his aids, and he declares that this operation, although serious, yet is so certain in its results at the time and later, that it is justified in all cases where the anatomic conditions seem to promise difficult delivery requiring forceps or version. Also when conditions render rapid termination of the pregnancy or delivery desirable and the cervix is still resistant. Of course under the reserve common to all indications that there is no risk of infection. In 5 cases he practiced cesarean section on account of a prolapsed ovarian cyst. After evacuation of the uterus he excised the cyst, a simple intervention as cysts which allow pregnancy are generally free from serious adhesions. With a fibroma praevia the indications are the same, provided myomectomy is easy; if not, hysterectomy is usually indicated. He extends the indications far in cases of mechanical obstacle to delivery, but draws them very close in case of disease in the mother as the danger of infection is great here. With eclampsia, for example, the mothers are often infected, and cesarean section has given deplorable results. Some have reported a mortality of 48.2 per cent.; Williams has compiled 7 deaths from sepsis among 85 eclamptic women treated by cesarean section. Bar himself has done the high cesarean section only in 2 cases of eclampsia, and neither woman had fever; one had only the menace of convulsions and the other had had only a few, and the ovum was intact. With placenta praevia he would not venture high cesarean section unless the hemorrhage had been grave to start with, the cervix not dilated, the membranes not accessible. These conditions are so rarely encountered that he has done cesarean section only in 3 such cases during the last ten years. All the possible objections against prophylactic cesarean section are counterbalanced by the long list of mutilating interventions, gangrene of fibromas, torsion of cysts, and death of the children which have often followed expectant management.

Densimetry in Radioscopy.—De Abreu says that it is as absurd in roentgen work to be content with the usual record, "semi-opaque shadow," "veil," "completely opaque," etc., as it would be to say the patient has "a little temperature," "much temperature," "considerable fever," etc., instead of recording the degrees. A series of sheets of tin can be used for the densimeter scale, radiographing it at the same time as the part being examined. A still simpler device is to compare the shadows with certain bones. The ribs correspond to the shadow cast by 2 or 3 cm. of water; the clavicle to 4 or 6 cm. of water; the heart to 7 or 8 cm. of water; the ribs and clavicle superposed, to 6 or 9 cm. of water; the ribs and heart superposed, to 9 or 11 cm.; the liver to 15 or 20 cm. This anatomic scale is convenient, and the findings can be recorded by the figures representing the density of the corresponding water.

Operations on Diabetics.—Blum distinguishes between the surgical affections which are quite independent of the diabetes and those connected with the disease. The general rules of surgery apply to the former, but with the lesions determined by the diabetes or connected with it, preliminary dietetic treatment is imperative. In the milder forms of diabetes, the results can be only favorable. In the graver cases, energetic dietetic treatment should be given for forty-eight hours at most, carbohydrates one day, fasting the next. Then the operation should be done without further delay if it is deemed wise to attempt it at all. It has been his experience that surgical complications set up a vicious circle in diabetes. His experiments and clinical research have shown further that chloroform is especially harmful and should never be used for diabetics. Diabetic coma after ether is also not infrequent, although many surgeons have performed successful operations under ether. Local and spinal anesthesia would be preferable if it were not for the emotional shock of the intervention which counterbalances the advantages of abstention from general anesthesia. Sodium bicarbonate should be given by the mouth or vein as long as the danger of coma persists.

Diabetes and Acromegaly.—Labbé's case has already been mentioned in these columns, page 1786. Study of this and similar cases on record of associated diabetes and acromegaly confirms the existence of a type of nervous diabetes in which the disturbance in the control of sugar metabolism seems to be of the same nature as in liver or pancreas diabetes. It suggests that the sugar metabolism is under the control of a complex physiologic apparatus that comprises the liver, the pancreas, the nervous system and the ductless glands. Disease in any part of this apparatus may suffice to bring on diabetes.

Glycemia.—Baudouin found that in the healthy fasting subject the sugar content of the blood keeps tenaciously at about 1 gm. per liter. Above 1.3 or below 0.9 gm. indicates pathologic conditions. Every hyperglycemia, no matter how slight, is necessarily associated with an increase in the normal glycosuria. It escapes detection usually until the glycemia reaches at least 1.7 gm. The glycemia fluctuates widely in the same person with the diet but, to date, this has been studied only with carbohydrates. Ingestion, fasting, of 100 or 150 gm. of glucose showed a rise of from 1.12 to 2.32 gm. in one hour (five times the normal rise) in persons with intermittent or subcontinuous postprandial glycosuria. In four cases of continuous glycosuria, the glycemia averaged 3.7 gm. per liter but it ran up to 5.61 after the glucose test. These figures show that in studying diabetic glycemia one test does not signify much. In advanced diabetes the kidneys become so impermeable that the sugar content of the urine grows less and less although the glycemia grows progressively more pronounced. In conclusion he urges the importance of studying the blood as this is a living witness to what is going on in the interior of the body. Between the normal response to the alimentary glucose test and the extreme response in diabetes there is a transitional group, a condition of prediabetes, with a response midway between the others. He has obtained this response in certain cases of liver disease, of gout, eczema, neuralgia or obesity or manifestations of the arthritic diathesis. The high alimentary glycosuria and high glycemic coefficient is certainly significant.

Glycuronic Acid in the Urine with Liver Disease.—Chiray reports considerable experimental and clinical experience with tests for glycuronic acid in the urine in normal and pathologic conditions. He commends Roger's simple technic for the purpose, precipitating with subacetate of lead, centrifuging and adding naphtho-resorcin and hydrochloric acid. Glycuronuria requires an intoxication with the aromatic bodies and a defensive reaction on the part of the liver. He studied it in dogs, rabbits and guinea-pigs as well as in man, inducing experimentally the production of glycuronic acid by giving 0.5 gm. of camphor by the mouth or injecting camphorated oil. The reaction reaches its maximum at about the third hour. With marked insufficiency of the liver there was no response to ingestion of 0.5 or even 1 gm. of camphor. On the other hand, the response was always pronounced in pathologic conditions in which the liver functioning was not impaired. The bibliography appended cites only one American publication.

Nerve Control of Movements of Head.—Bard's data and arguments apparently sustain his assertion that the external branch of the spinal accessory nerve is the nerve mainly involved in turning the head.

Test for Activity of Gastric Juice.—Loeper and Binet affirm that the hemolytic action of the gastric juice is a simple and practical means for estimating its potency. The rapidity and the intensity of the hemolysis are a reliable gage of the chemical activity of the gastric juice. They remove the plasma from 10 drops of human blood by rinsing three times in physiologic saline and centrifuging three times. Then they distribute the blood in test tubes containing dilutions of gastric juice from 1:4 to 1:10, in the proportion of 2 drops to 2 c.c., and incubate at 37 C. Normal juice, titrating 1 gm. HCl, hemolyzes the 1:4 dilution in fifteen minutes; a hyperactive juice in three minutes; an inactive juice not even in forty-five minutes. The hemolysis occurs the same whatever the source of the human blood corpuscles. The hydrochloric acid is evidently the main but not the sole factor involved. There was no evidence of hemolysis with this test in their cancer cases, but the hemolytic response was extremely intense with hyperchlorhydria and with gastric ulcer.

Serotherapy of Erysipelas.—Basset published last year the fine results he had obtained in various acute local infections, lymphangitis, anthrax, phlegmons, etc., from subcutaneous injections of a polyvalent antiserum (Leclainche and Vallée). He has since applied this treatment in sixteen cases of erysipelas and found it particularly rapid and effectual in its action in this disease, supplemented by local measures. The dose was from 20 to 40 c.c. of the antiserum, and the fever and the patch subsided in from two to six days. Painting with iodin twice a day seemed the simplest and most active of the local measures tried.

*Voltaic Inclination of Head and Trunk. L. Bard.—p. 73.
*Sequelae of Pleurisy. M. Péhu and M. Daguet.—p. 101.

Hysterotraumatism from Medicolegal Standpoint.—Pitres and Verger discuss traumatic disability from the standpoint of French law and recent court decisions, comparing the findings in civilian and military cases. Pitres' views were recently summarized in these columns, page 1706, in an abstract from an article by Cruchet. Pitres here remarks that since Sydenham called hysteria *la grande simulatrice,* because the symptoms which it induces often resemble those which develop in many other affections, it has had a very bad reputation. It has gradually been assumed that more or less simulation was a factor in all cases of hysteria, but when Pitres and Verger had over 15,000 men pass through their hands in the centre de neurologie of the 18 Région they soon saw the necessity for classifying the nervous post-traumatic cases in two groups, those with true and pure hysteria, and those of simulation, exaggeration or perseveration. They state that it is easy to distinguish between these groups. In the false cases the contractures are only vicious attitudes complacently retained. The "paralysis" is more a weakness, and it becomes manifest in walking or when there is work to be done with the arms. The algias increase in number and change location with each medical examination. There are no vasomotor, thermic or trophic disturbances, and the electric reactions are normal. The mental state is also different from the true hysteria cases; with the latter the men do not seek to inspire sympathy but seem normal and resigned, without excessive indifference. If there has been a psychic process in which the fear of the evil has engendered the evil, as some affirm, it occurred in the depths of the subconsciousness. Some recover rapidly, especially if treated soon after the injury; others have only gradually recovered in the course of years, while some are still in the same condition after years as during the first month after the injury.

Influence of the Nervous System on Glycemia.—Lépine reports the results of extensive experiments on dogs and describes the mechanism of the rise in the sugar content of the blood in consequence of puncture of the floor of the fourth ventricle, of concussion of the brain, of stimulation of the central end of the sciatic nerve, etc., and the hypoglycemia which follows puncture of the upper portion of the spinal cord. He adds that the disappearance of the sugar from the cerebrospinal fluid with syphilis of the nervous system may have differential importance, as in conditions with similar symptoms from other causes the sugar content is generally abnormally high, as in epilepsy, for instance.

Pathologic Modifications of Voltaic Inclination of Head and Trunk.—Bard refers to Babinski's work in this line of twenty years ago and describes different ways in which to elicit this test of disturbances in the labyrinth and gyration centers, and interpretation of the responses.

Sequelae of Pleurisy.—Péhu and Daguet have been studying the immediate and the remote sequelae of serofibrinous pleurisy and they discuss the relations between the radioscopic and the clinical findings. They were impressed with the complete restitution of normal conditions after a traumatic effusion while the effusion of a spontaneous pleurisy always leaves traces, some shadow or modification of the excursions of the diaphragm. Radioscopy is indispensable in internal medicine, they reiterate, and frequent radioscopic control is required particularly in pleurisy with effusion. They have had the opportunity to reexamine a total of 272 pleuritics after intervals of a few months up to twenty years.

*Herpes of the Cornea. Sidler-Huguenin.—p. 561.
*Prophylaxis of Endemic Goiter. R. Klinger.—p. 575.

Alleged Traumatic Herpes of the Cornea.—Huguenin presents arguments to disprove the assumption that trauma can be incriminated in the etiology of herpes of the cornea. It is an endogenous process, and a predisposition to herpes is an important factor. In 65 cases from his practice in the last twenty years, 28 had the herpes recur two or three times, and in 6 it returned *four times* in the same eye and in 8 cases the other eye was affected. In some of his cases there was no sign of herpes after a severe trauma of the eye, but it developed immediately after an intercurrent influenza. The first manifestations of the herpes are liable to resemble an erosion, and the subject at once begins to try to remember some accident to his eye. It is very suggestive, he adds, that in the 25 so-called traumatic cases of corneal herpes that he has encountered, the patients, with 5 exceptions, had all been insured against accidents. He adds that this does not necessarily imply malingering on their part, as workers are so liable to injury from flying scraps. In treatment, Huguenin advises bed rest and a light bandage over both eyes for a few days. The herpes may retrogress without loss of substance when the lesion is thus protected. He warns that yellow ointment is as harmful with herpes of the cornea as it is useful with other affections of the cornea. Moist heat is more effectual in aiding healing than yellow ointment. In any event it should never be massaged in. The prognosis is generally favorable if secondary infection can be warded off. Even if vision is impaired by a centrally located cicatrix, conditions may become materially improved in the course of one, two or three years.

Endemic Goiter.—Klinger describes the efforts in this line at Akron, Ohio, as reported in the *Archives of Internal Medicine,* **22**:41, 1918. He urges the adoption in Switzerland of similar measures, as the Akron experiments proved the absolute harmlessness of the measures enforced, namely, administration of 0.2 gm. sodium iodid daily, for ten days, spring and fall. Only 5 of the total 1,000 girls thus treated showed any signs of intolerance. The Akron experiment was described also in The Journal, Dec. 28, 1918, p. 2155.

*Gonococcus Vulvovaginitis. S. Maggiore.—p. 257.
*Congenital Goiter. A. F. Canelli.—p. 264.
*Viscosity and Coagulability of the Blood. M. Sindoni.—p. 278.

Gonococcus Vulvitis in Little Girls.—Maggiore reports seven cases to illustrate the advantages of treatment of infantile gonococcus vulvovaginitis with tannic acid in powder form. The secretions in the vulva and at the opening of the vagina are washed off under a stream of 1 per twenty thousand solution of potassium permanganate, without pressure, and the parts are dried with cotton. Then they are dusted with a thick layer of tannic acid and a small pad of cotton is applied and held with a bandage. Each time the child urinates the powder is applied anew. It sticks long to the tissues and exerts a mild antiseptic action. The results have been very encouraging in his experience, the most rebellious forms of the vulvitis soon healing under this treatment. The children were from 5 to 10 years old and the disease was of one or two weeks' standing, and recovery was complete in from one to three weeks at most. This technic requires less manipulations than with fluids.

Congenital Goiter.—Canelli found the thyroid enlarged in 4 of 70 cadavers of infants prematurely born or living only for a few days. In 12 he weighed the thyroid systematically and found that it averaged 0.66 per thousand of the weight of infants born at term, and 0.256 per thousand in the prematurely born. Comparing these findings with similar data on record seems to establish that the maximal weight of the normal thyroid is 4.85 gm. In 4 of the 70 cadavers the thyroid weighed from 7.1 to 21.5 gm., the infants weighing only from 1,490 to 2,800 gm. No trace of iodin was found in the thyroid that weighed 7.1 gm., from an 8 months fetus, but 0.007015 gm. iodin was found in the largest thyroid, the infant born at about term.

Viscosity and Coagulability of the Blood in Different Diseases.—Sindoni records the figures for the viscosity and for the coagulating time in a number of children with pernicious anemia, chloroma, kala-azar, malaria or congenital heart disease, and also in three normal children. When the number of corpuscles is low, the viscosity is also much reduced. The coagulation time is slightly retarded as the viscosity grows less. In kala-azar, under tartar emetic treatment there was no modification of the coagulability.

*Measurement of the Heart. P. Alessandrini.—p. 545.
Influenza and Its Causes. S. Belfanti.—p. 548.
Pseudosuicides. A. Carelli.—p. 559.

Measurement of the Heart.—Alessandrini tabulates the findings in nine typical cases of different forms of valvular disease and compares them with Clayton and Merrill's table showing the longitudinal and transverse diameters, the product of the two, and the index, which represents the ratio between the two. The highest figures were obtained in a case of aortic insufficiency plus mitral stenosis, the longitudinal diameter being 17, the transverse 16.5, their product, 280.50, and the index 0.97. An index above 0.96 is always pathologic, as it testifies to enlargement of the right heart. A normal index with high product indicates a total enlargement of the heart cavities. With enlargement of the left half alone, the index is low. Radioscopic measurement of the heart in this way classifies the case at once.

April, 1919, **26**, Surgical Section No. 4

*Classification of Cases of Enlarged Prostate. E. Pirondini.—**p. 113.**
*Projectile near Sacral Vertebra. D. Taddei.—p. 140.
*Phlegmons of the Pharynx. B. Masci.—p. 146.
Stenosis of the Esophagus. A. Austoni.—p. 150. Cont'n.

Indications for Operation with Enlarged Prostate.—Pirondini has been applying his method of experimental azoturia in the classification of "prostatics," and has drawn what he thinks are important deductions therefrom in regard to the treatment. This is particularly important as the kidneys suffer more than any other organ from the effects of transvesical prostatectomy, and as the ureter catheter cannot be used with hypertrophied prostate, and both kidneys generally have been more or less damaged in consequence of this hypertrophy. He applied the test in 40 cases of hypertrophied prostate, and also in a number of other persons normal or with kidney or bladder disease. (The test is ingestion of 10 gm. urea, in 300 c.c. distilled water, as described in THE JOURNAL **68**:496, 1917.) This is a physiologic functional test, as urea is a natural constituent of the urine. He found that 45 per cent. of the prostatics responded normally to the test azoturia; 32 per cent. gave a very defective response, and the rest gave an intermediate response. They could thus be classed in three groups. Those in the first group with limpid urine outside of the periods of acute retention, with normal response to the test azoturia, should be operated on at one sitting, unless there are special visceral lesions. With a defective or very bad response to the urea test, the operation should be done in two sittings, and there should be a period of preparation, retention catheter and hypogastric drainage. In this group, with very bad response to the urea test, the benefit on the part of the kidneys from the preparation may not be so great as anticipated. The general improvement may far surpass the improvement in the kidneys, and this may render the operation a success. The patient may long survive without ever presenting symptoms of renal insufficiency, although it is scarcely probable that the functional balance has been completely restored. An operation at one sitting might be justified even for prostatics with a rather poor response, provided the preparation for the operation had been long and thorough. This functional subdivision of cases of hypertrophied prostate into three groups or stages is thus a reliable guide for the management of different cases, as he shows by the detailed history and the outcome in a number of instances.

Projectile in Front of Fourth Sacral Vertebra.—Taddei successfully removed the projectile and cured the old fistula by an ischiorectal incision. Linear incision of the rectum and simple section of the anus does not seem to interfere with defecation later.

Phlegmons in Pharynx.—Masci found streptococci in the acute idiopathic phlegmons in the pharynx of the man of 57. Incision of the phlegmon gave great relief, but the man died a few days later. No treatment to date has proved effectual in these cases, but antistreptococcus serum, intravenous injection of colloidal metals, heart stimulants, and ice should be tried, with other general and local measures.

Annaes Paulistas de Med. e Cirurgía, S. Paulo, Brazil

January, 1919, **10**, No. 1

Influenza at S. Paulo. L. Torres.—p. 1; R. Puech.—p. 14.
*Cysticercus in Eyeball. P. Gomes.—p. 17.

Cysticercus in Eyeball.—Gomes' description of two successful operations for cysticercus in the eyeball is given only in Society Proceedings as he reported the cases to the local medical society. The larva was in the anterior chamber in one man of 30 and free in the left vitreous humor in the second case, the patient a man of 32. The operation was like that for cataract in the first case, but in the second case Gomes was much gratified by the success of the special method used. Instead of puncturing the sclerotic he made a small radial incision, then had the patient raised to a sitting position, keeping the head bent over low to the left, the eyeball still turned upward and inward, toward the frontal sinus. With the ophthalmoscope it was then verified that the cysticercus was close to the incision. An attempt was made to grasp it with iris forceps but proved unsuccessful. A second introduction of the forceps, however, seized the larva and it was easily drawn out through the minute incision. The patient was then placed horizontal and the incision was sutured with U stitches of fine silk. The sclerotic did not have to be sutured as the radial incision had been made in the same direction as its fibers. Although echinococcus disease is comparatively frequent in Brazil, he knows of only one other case of intra-ocular cysticercus in the entire country.

February, 1919, **3**, No. 2

*Gastro-Intestinal Catarrh. F. C. Aguilar.—p. 65.
*Congenital Dislocation of Hip Joint. J. Riosalido.—p. 80.
*Intubation in Diphtheria. S. G. Vicente.—p. 86.

Gastro-Intestinal Catarrh.—Aguilar discusses whether catarrhal conditions necessarily imply infection, and whether infection always induces catarrhal conditions in the digestive tract. He says that neither question can be answered summarily in the affirmative. The catarrhal condition is primarily physiologic, and infection may exist without symptoms indicating a catarrhal state in the digestive tract. He has had cases of gastric or intestinal catarrh in which the only symptom seemed to be fever. In some cases it reached 39 C. and was frankly intermittent.

Congenital Dislocation of Hip Joint.—Riosalido does not follow Lorenz' technic but makes the reduction systematically by way of the notch below instead of by the posterior margin of the acetabulum. The leg is flexed on the trunk, while an assistant holds the pelvis firm by the crest of the ilium on each side. The leg is flexed on the pelvis until the anterior internal aspect touches the trunk. This brings the head down in front of the notch and with brief abduction it slips into the socket. He has never had occasion to push up the trochanter to accomplish this, but would not hesitate to do this in difficult cases. He never does myorrhexis like Lorenz, but insists that it is very important to respect the muscles. He applies the plaster cast in Wendorf's position, that is, flexion at an acute angle, abduction less than 90 degrees and inward rotation. The cast should include the leg to below the knee and the pelvis to the ribs. In four months this cast is changed for one that allows a more normal position. In one case in which the first cast had been worn for more than four months the retraction of the muscles was so extreme that the change to the second position had to be done extremely gently and cautiously, at two sittings, to avoid fracturing the bone. When the second cast is removed, after three or four months, then vigilant supervision is imperative. The child must avoid flexing the hip joint, especially by sitting on a low seat. When the child sits down the seat must be high, and the child must sit only on the edge of the seat. In walking, the knee and hip joint must be held stiff, and only short steps taken, at first very slowly, the hands held high by an older person. After a week the child can walk alone aided by long poles which force it to hold the body erect. No massage or special exercises are enforced. The child under vigilant supervision gradually recovers the full functional use of the limb. With a unilateral process, he allows the child to walk while it is in the second cast, the foot raised. In one bilateral case sciatic paralysis developed with pain, fever and other symptoms suggesting meningitis until the immobility of the toes attracted attention. The sciatic nerve had evidently been compressed. In another case there was tardy deforming osteo-arthritis of the joint involved.

Intubation in Diphtheria.—Vicente believes in leaving the tube tranquilly in the throat, changing it occasionally for a larger size, and keeping the child well fed and out of doors where it can run and play. When the tube is finally discarded, he says, *vigilancia exquisita* is indispensable. This care of the intubated child is easily realized in proper institutions but is much more difficult in the home.

*Radium and Dermatology. E. A. S. de Aja.—p. 269. Conc'n.
Pulmonary Tuberculosis Simulating Malta Fever. A. N. Blasco.—p. 272.
*Paranoia. S. Herreros.—p. 277.

Radium in Dermatology.—De Aja here reviews his extensive experience with radium treatment of skin lesions and diseases in the last two years. Epitheliomas, without reaction in the glands, subsided almost constantly under radium treatment, as also in the graver cases when associated with operative measures. Even in the inoperable cases, the relief of pain and hemorrhage and suppression of secondary infection afford great benefit. Radium proved inferior to the roentgen rays as a depilator, and also in treatment of pruritus. The action is slow in lupus but reliable, and only occasional success was realized in common eczema, but in the lichenoid form the results were brilliant, as also with eczematids, and in eczema of hairy regions. Seborrhoids heal under radium and effectually, but the most unexpectedly brilliant results were obtained with ordinary suppurating lesions of the skin, pyodermatitis. He emphasizes that the indications in this line should be extended.

Paranoia.—Herreros expatiates on the necessity for recognizing early a tendency to paranoia and warding it off by instruction and training. A simple defect in character may become transformed into mental derangement by some trivial cause. In the period of delirium, the physician cannot aid much except by combating the hallucinations. Sedatives may give great relief, but the delirious ideas should not be discussed. The persons that develop ideas of persecution have usually been timid, self-centered, querulous persons, not making the effort necessary to "take a high place at the banquet of existence." A physician's advice and sympathy at this time might divert the patient's ideas into wholesome channels. Auditory hallucinations are a potent element in the development of delirium, and for this and other reasons cited the incipient paranoiac should be placed in the institutional charge of a good alienist where he will get the food, the quiet, etc., needed.

April 5, 1919, **7**, No. 74

*The Stomach Tube. F. F. Martinez.—p. 1.
Hemorrhagic Pleurisy. G. Triviño.—p. 4.
*Malignant Pterygium. G. González.—p. 5.

The Stomach Tube.—Martínez compares various methods for catheterization of the stomach and states that he prefers a rather stout tube, No. 12 or 13, the hardest to be obtained. He never calls on the patient to swallow the tube but bids him to keep passive. All he has to do is to concentrate his energies on breathing deep and forcibly.

Malignant Pterygium.—González reports a case in which an extensive pterygium had returned five times after operative removal, and enucleation of the eye was being considered on account of fear of a malignant nature. Then he severed the large vessels nourishing the pterygium, an actual peritomy, and injected into the center of the pterygium 3 or 4 drops of a 3 per cent. solution of a preparation of thiosinamin. In the course of forty days nine injections were thus made at different points in the pterygium, increasing the strength from 3 to 10 per cent. as it atrophied. The retrogression is complete but the relics of the five operations are irreparable although the visual field has become larger and the movability of the eye greater. There has been no trace of recurrence during the months since.

Plus Ultra, Madrid

January, 1919, **2**, No. 7

Bacteriologic and Clinical Study of Influenza. P. Mayoral, R. Lobo, J. Olano, E. M. de Nicolás and J. González.—p. 5.
*Functional Exploration of the Duodenum. F. F. Martínez.—p. 14.
*Treatment of Convergent Strabismus in Children. Cilleruelo.—p. 18.
*To Estimate Blood Lost in Hemorrhages. M. Sáiz.—p. 23.
Sensory and Motor Disturbances in the Larynx. Prada.—p. 24.
*Dissection of Biliary Passages. P. Belou.—p. 33.
*Implant in Treatment of Hernia. A. H. Carmona.—p. 34.
*Differential Diagnosis of Neurasthenia. C. Juarros.—p. 45.
Psychology of Regicides and Magnicides. A. Lecha-Marzo.—p. 48.
Modern Medical Electric Apparatus. F. Reber.—p. 51.

Exploration of the Duodenum.—Martínez describes the simple technic with which he obtains duodenal contents and applies the tests for the various ferments, cholesterol, etc. He uses a heavy perforated metal capsule, about 1 by 2 cm., formed of two cups that screw together. The only test meal, he says, that does not clog the openings is a couple of eggs beaten up in a pint of milk.

Convergent Strabismus.—Cilleruelo discusses the different technics in vogue for treating strabismus in children, and declares that simple or double tenotomy is the best and safest.

To Estimate Quantity of Blood Lost in Hemorrhages.—Sáiz remarks that the number of corpuscles in the blood after a hemorrhage is necessarily much reduced although the total volume of the blood fluid soon returns to normal. Comparing the number of reds found after the hemorrhage with the normal number, gives an approximate estimate of the amount of blood lost. Calling the normal percentage of reds 100, then the proportional percentage with only 3,968,000 reds, as in a case described, was 82.66. This means that there had been a loss of 17.34 per cent. of the reds. Accepting Cardenal's figure that the total amount of blood is $1/47$ of the body weight, then in this patient, who weighs 58 kg., it is easy to calculate from this that the amount of blood lost equals 591.46 c.c.

Dissection of Biliary Passages.—The two large colored plates showing the gallbladder region and the foramen of Winslow are not accompanied by much text as they speak for themselves. They seem to be fine specimens of color photography, nearly life size.

Implant to Reenforce Herniotomy.—Carmona has been applying in treatment of inguinal hernia the results of the research of Leriche and others in regard to the ossification liable with an implant of periosteum. He gives eight illustrations showing the exact technic. The rectangular strip of periosteum, about 3 by 6 cm., is cut from the periosteum of the tibia on the inner aspect of the leg, below the knee. After the herniotomy has been completed in the usual manner, he applies this strip of periosteum over the other suture, holding it in place with a stitch near each corner. In seven of eight cases in which this method was applied the implant healed in place by primary intention and there has been no disturbance of any kind since. The region of the herniotomy is tough and resistant, flexible at first but gradually becoming extremely hard, of a fibrous consistency. One of the patients was operated on by this technic on one side and without the implant on the other side, and there is already recurrence on the latter side. The fibrous hardness of the implanted side absolutely prevents any tendency to recurrence of the hernia.

Diagnosis of Neurasthenia.—Juarros warns that we must first of all determine whether the neurasthenic symptoms may not be the work of malaria or other constitutional disease, or the incipient phase of general paralysis or dementia praecox. He cites some typical examples in which examination of the stools revealing insufficiency of the pancreas permitted effectual treatment, with the vanishing of the assumed neurasthenia. Or the supposed neurasthenia proved to be the result of oxaluria, and subsided when this was conquered. The questions are: Is there such a state of fatigability of the nervous system as to justify the assumption of neurasthenia, and is this neurasthenia constitutional or acquired?

*The Public Health in Brazil during 1918. T. Torres.—p. 29.

The Public Health in Brazil During 1918.—Torres is the newly appointed chief of the public health service. Director geral de Saúde Publica is his official title, and he outlines here the pressing needs of the service and gives the statistics for Rio de Janeiro during 1917 and 1918. There were no deaths from yellow fever or cholera in either year and only 2 from scarlet fever in each year, but whooping cough was responsible for 209 and 182 deaths; pulmonary tuberculosis for 4,034 and 4,706; puerperal fever for 77 and 91; rabies for 8 and 3; and syphilis for 270 and 378. The great increase in the death rate was due to influenza. His statistics cite 411 deaths from "grippe" in 1917 and 12,622 in 1918, in a total mortality of 21,508 and 34,894 in the respective years.

Semana Médica, Buenos Aires

Physicopathology of the Aviator. J. A. López.—p. 349. Cont'n.
Radiography of Ventricles of the Brain. C. Heuser.—p. 352.

Intrapleural Treatment of Pulmonary Tuberculosis.—Escobar asserts that the intrapleural method of treating tuberculous processes in the lungs is certain to have a promising future, as it is the most direct mode of access to the lung; as the pleural serosa abounds in lymphatics connecting with the lungs; as it is permeable, and thus facilitates the exosmotic action of the medication on the lung tissue, and, finally, because the effusion which collects at once makes the treatment painless. He affirms further that tincture of iodin is the preferable topical treatment on account of its local and bactericidal action, its diffusibility, absorption and rapid elimination, and the way in which it modifies the soil. He gives the details of a case thus treated with 188 c.c. of tincture of iodin fractioned in twenty-two doses in the course of seven or eight months. About 3,630 c.c. of pleural effusion were withdrawn during this period. The young man had not been able to work for two years and tubercle bacilli were numerous in the sputum, but under this treatment and other measures he has apparently regained complete health and earning capacity.

Grèce Médicale, Athens

Jan. 1-15, 1919, **21**, Nos. 1-2

Successful Roentgen Treatment of Hypertrophied Tonsils. J. Cécikas. —p. 1.
*Autoserotherapy of Influenza. T. Anastassiadès.—p. 4.
Equipment for Prophylaxis of Rabies. J. Foustanos.—p. 6.
*Lethargic Encephalitis. G. Karyophyllis.—p. 8.
*Influenza. P. J. Rondopoulos.—p. 9.

Autoserotherapy of Influenza.—Anastassiadès reinjected the patient with the serous fluid from an induced autoblister. The mortality in 234 patients thus treated was 6 per cent. When the small disk of blistering plaster applied to the chest fails to induce a blister, the outlook is grave. He aspirates from 0.3 to 0.5 c.c. of the blister fluid and mixes it with strychnin, caffein or morphin according to the special indications at the time. The mixture is then injected at three points, above the blister region on each side of the chest, and in the abdomen. The effect was apparent at once, he says, and in thirty-six or forty-eight or even in twelve hours the temperature declined and the improvement progressed.

Lethargic Encephalitis.—The three cases described are the first recorded in Greece. The patients were young adults and the first symptoms appeared late in September or early in October, 1918. The two women died; the youth of 17 left the hospital about twenty-eight days after the symptoms had first appeared. He had not entirely recovered the use of his legs and the atrophy of the optic nerve was such that he could only distinguish day from night. His lethargy with closed eyelids lasted for over two weeks.

Influenza in Greece.—The first wave of influenza in June and July was comparatively mild, but the October wave had a mortality of 15.5, 22.7 and 24.23 per cent. in different localities. The maximum mortality was in the army hospitals, reaching 50.7 per cent. in some of the hospitals at the front.

Kitasato Archives of Experimental Medicine, Tokyo

April, 1919, **3**, No. 1

*Anaphylactoid Reaction to Arsphenamin. N. Hirano.—p. 1.
*Spirochete of Relapsing Fever in Manchuria. H. Toyota.—p. 43.
*Experimental Study on the Mixed Injection of Bacillus Influenzae and Various Species of Cocci. S. Yanagisawa.—p. 85.

The Anaphylactoid Reaction to Arsphenamin. — Hirano entitles his article, which is in English, "Experimental Studies on the Investigation of the Nature of Anaphylactoid Caused by the Repeated Injection of Salvarsan," explaining this as the sudden congestion of the face, feeling of oppression in the chest, dyspnea, cough, and pain in the back, with a sensation of distress, which may develop during the infusion but disappears afterward without ill effect. He reviews the literature on the subject, and reports experimental research which sustains Milian's statements in 1913 to the effect that preliminary injection of epinephrin will ward off these symptoms. Hirano's work was done on large numbers of rabbits, and the results of the tests are tabulated. They show that a remarkable decrease in the chromaffine substance in the suprarenal glands follows intravenous injection of a large quantity of either arsphenamin or neoarsphenamin, and intravenous injection of even a therapeutic dose of arsphenamin is followed by a reduction in the epinephrin content of the suprarenals. The epinephrin content of the blood decreases at once after injection of either but increases again a little later. The epinephrin content of the suprarenal glands of rabbits after the three weekly intravenous injections of 0.02 gm. per kilo body weight was sometimes found higher than in normal animals. But no remarkable decrease in the epinephrin content of the suprarenal glands followed a therapeutic dose of arsphenamin given animals so treated, and no difference from normal animals was noted after a therapeutic dose of neoarsphenamin. On the other hand, after three weekly intravenous injections of 0.03 gm. per kilo body weight, the epinephrin content does not differ from that of normal animals, but if a therapeutic dose of neoarsphenamin is given to animals thus treated, a remarkable decrease in the epinephrin content of the suprarenal glands is observed. The arsphenamin anaphylactoid seems to be a set of symptoms which are produced when a sudden decrease of the epinephrin content of the circulating blood occurs when it cannot be resupplied by the epinephrin system in sufficient quantity or promptly enough. It is significant that arsphenamin and neoarsphenamin each arrest the epinephrin-mercuric chlorid reaction in the test tube.

The Spirochetes of Relapsing Fever in Manchuria.—Toyota comments on the differences between different strains of spirochetes found in patients and the differences observed in those cultivated from mice and through generations of mice. Even in the single epidemic, strains are encountered which differ widely in various characteristics and immunity reactions. At the same time, after repeated passages through animals they seem to veer to a more uniform type. The article is in German.

Experimental Mixed Infection with the Influenza Bacillus.—Yanagisawa reiterates that the causative agent of the present pandemic of influenza has been recognized as Pfeiffer's influenza bacillus by the workers at the Kitasato Institute. The possibility of an invisible virus seems to have been disproved by the invariably negative results of Kusama's experiments on healthy persons with diluted and filtered sputum. Yanagisawa's experimental research apparently demonstrates that in the pandemic the influenza bacillus first enters the respiratory system and develops the typical symptoms of the disease if no cocci are present. If, on the other hand, it enters into symbiotic relations with cocci, it intensifies the toxic action of the latter and the secondary symptoms from them overshadow those from the influenza bacilli, and the latter may actually be crowded out.

Comparative Microscopic Anatomy of Vertebrates.—The vertebrates studied were on the order of urodela and gymnophiona, and the microscopic findings in the digestive tract of these amphibians are reproduced in fifteen large plates.

Nederlandsch Tijdschrift v. Geneesk. Amsterdam

March 22, 1919, **1**, No. 12

Style in Medical Writings. G. van Rijnberk.—p. 893; A. Kluyver.—p. 895.
*Comparative Anatomy of the Otoliths. F. H. Quix.—p. 902.
*Periodicity in Disease. J. H. F. E. van Hunsel.—p 913
Serodiagnosis of Typhus. P. H. Kramer.—p. 922.
*Return to Venesection. C. A. Ide.—p. 923.

The Otoliths.—Quix presents evidence to sustain his assertions that geometrical and mathematical analysis of the pressure exerted and experienced by the otoliths opens up a new field for research on the sense of equilibration. The disturbances in man and animals after removal of one or both labyrinths are also instructive in this line. With congenital caput obstipum the head is held in exactly the same way as a rabbit holds its head after removal of the labyrinth on one side. If this finding should be confirmed in other cases, it would suggest as the cause of caput obstipum that the muscular contraction is a reflex phenomenon from the otolith sacculus of the otherwise normal sense of equilibration.

Periodicity in Certain Infectious Diseases.—Van Hunsel calls attention to the periodicity in the appearance of the skin lesions in his experimental tuberculosis. The skin lesions appeared and reappeared in seven day cycles or multiples of seven. The death of two of the animals occurred on the eighty-fourth and the hundred and seventy-fifth day, both multiples of seven. Certain physiologic processes, menstruation and rut return in cycles of multiples of seven. Typhoid usually runs its course in seven-day periods, but a one or two-weeks course is exceptionally marked in scarlet fever, as a rule. The tardy effects of gassing also usually appear after one or two weeks. The records of eruptive diseases display also this one or two weeks' course, the first outbreak of the eruption frequently falling on the fourteenth day after infection. These and other facts cited seem to show the action of certain powerful forces, all working in the same direction, and taking for this, certain regular periods of time. This uniformity seems to exclude the action of the widely diverse antigens as responsible for it. It is much more plausible to assume that the human or animal organism impresses its influence on the foreign invaders and thus determines the periodicity of the phenomena observed.

Rehabilitation of Venesection.—Ide remarks that over 50 per cent. of his influenza patients had more or less epistaxis, and he accepts this as one of Nature's most important means to combat the infectious process. If this premise is accepted, then it is a question whether venesection should not be regarded as an important adjuvant in acute infections.

*Tremor during General Anesthesia. T. Rietz.—p. 330.

Tremor During General Anesthesia.—Rietz noticed in 28 cases the development of a tremor during general anesthesia which resembled in character and course the rhythmic phenomena observed at times with irritation of motor tracts. His study of its mechanism revealed a means to control it, namely, by shutting off partially from the brain the blood laden with the anesthetic. This he accomplished by pressure on the carotid artery. The tremor ceased at once in 16 of the 25 cases in which this was done and it became much reduced in 4 others, but no effect was apparent in the 5 others.

Upsala Läkareförenings Förhandlingar

Jan. 20, 1919, **24**, Nos. 1-2

*Poisonous Mushrooms. C. T. Mörner.—p. 1.
*The Lymph Glands. T. J. Hellman.—p. 57.
Views of Elderly Physicians on the Medical Career. R. Friberger.—p. 137.
*Invagination of Colon in an Adult. G. Nyström.—p. 151.

Poisonous Mushrooms.—Mörner relates that for twenty years he has been collecting data for this study of poisonous mushrooms, compiling articles on this subject by physicians, chemists, botanists, pharmacologists, hygienists and statisticians. The clinical side of mushroom poisoning seems to be thoroughly known but the chemical and pharmacodynamic side has still many gaps in our knowledge, notwithstanding the extensive literature. Possibly the problems involved are technically exceptionally difficult of solution. He gives eight pages of references, with the titles in full, and five colored plates showing various species of mushrooms at different periods of growth.

The Lymph Glands.—Hellman reports extensive microscopic research on the lymph glands as a protecting organ in general and as protecting against cancer, tuberculosis and anthracosis in particular. Among the points thus learned is that cancer cells and tubercle bacilli seem to arouse a biologic reaction in the lymph gland as they reach its surface, and this reaction impedes their further penetration into the gland. Particles of coal do not rouse this reactive process and consequently they work deeper and deeper into the gland and are found even in the center, while cancer cells and tubercle bacilli are found in the periphery, and the cancer metastases develop in the marginal sinus. Three plates reproduce the microscopic and macroscopic findings in several cases, presented by Born's "reconstruction method." Six pages of bibliography on the early involvement of the lymph glands in cancer and tuberculosis are appended, with a brief summary in German.

Invagination in Adult.—Nyström's patient was a man of 38 and the invagination involved the transverse colon. It was corrected by a laparotomy, with recovery. The pains in this case were not of the colic type and they were located in the lower bowel so that they suggested bladder disease, especially as there was complete retention of urine the second day and the man vomited, but the vomit was not fecaloid even up to the fourth day. There was a tendency to diarrhea and the second night the stools showed fresh blood. At the laparotomy the fourth day, the invagination was reduced and the greater omentum was brought down over the excessively long transverse colon, to prevent further invagination, and was held with fine catgut stitches.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JANUARY-JUNE, 1919

The following journals have been abstracted in the Current Literature Department of THE JOURNAL during the past six months. Any of the foreign journals, except those starred, will be lent by THE JOURNAL to subscribers in the United States and to Fellows of the American Medical Association for a period not exceeding three days. Only one journal may be borrowed at a time. Requests for periodicals should be addressed to the Library of the American Medical Association and six cents in stamps should be enclosed. This covers the average expense of mailing a journal. Domestic journals can be obtained by sending the approximate amount direct to the respective publishers. Thus most of the journals indexed are accessible to the general practitioner, no matter where he may be located.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "E," Editorial; "C," Correspondence; "T," Therapeutics; "Ml," Medicolegal; "P," Propaganda for Reform; "ME," Medical Economics; "ab," abstract; the star (*) indicates an "Original Article" in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths" and "Society Proceedings" are indexed under these titles at the end of the letters "B," "D" and "S." Matter pertaining to the Association is indexed under "American Medical Association." The name of the author follows the subject entry in brackets.

For author index see page 1983.

A

- ABDERHALDEN REACTION: See also under names of various diseases
- ABDERHALDEN REACTION during first month of life, [Caronia] 382
- ABDOMEN cancer, dyspnea in relation to, [Mejia] 1650
  - gas tensions of, with evidence on diffusion of gases within body, [Haggard & Henderson] 1641
  - incision, simple and expeditious method of performing, [Bland] 453
  - influenzal complications within, at *Camp Custer*, [Beals & others] *850
  - influenzal intra-abdominal catastrophies, [Smith] 1192
  - pain with incipient pneumonia and febrile rheumatism, [Clark] 689
  - pendulous, extreme, and surgical treatment by new three-flap operation, [MacLean] 682
  - perforations of abdominal viscera, [Mayo] 452
  - Ptosis of: See Splanchnoptosis
  - reflexes, significance and surgical value of, [Ligat] 1644
  - war surgery, 437
  - wound, gunshot, transfusion of blood after, [Fonio] 614
  - wounds, war, sequels of, [Stassen] 900
- ABORTION case, intent and revocation of license in, 957—Ml
  - criminal, protection of child against, [Chambrelent] 1942
  - from oleum sabinae, fatal, [Welcker] 317
  - induced, causing sterilization, pathologic conditions of pelvic viscera result of, [Reder] (14) 141
  - medical, [Hermosa] 1711
- ABSCESS: See also Phlegmon; and under names of organs and regions
- ABSCESS, amebic, of brain, following amebic abscess of liver, [Armitage] 1705
  - amebic, of liver, emetin with, [de Bellard] 1335
  - cold, zinc treatment of, [Sztark] (45) 228
  - fixation, in influenza, [Vergely] 967
  - intraperitoneal, containing roundworms, [Jackson] *412
  - tuberculous, in wall of chest, [Iselin] 1039
- ACADEMY of Medicine, Lima, 1016
  - of Medicine, Mexico, 1014
- ACCIDENTS, industrial, causation and prevention of, [Vernon] 1330
- ACETANILID, 1828—T
- ACETONE, effect of β-hydroxylbutyric and acetoacetic acids and acetone on blood catalase, [Burge] 1031
  - effects of ether and, on respiration, [Gustafson] 758
- ACETPHENETIDIN, 1223—T
- ACETYL-AMIDO-ETHOXY BENZENE: pertonal, [Cambridge] 1032
- ACHYLIA GASTRICA, [Warr] 1250—ab
- ACID, acetoacetic and β-hydroxylbutyric acids and acetone, effect of, on blood catalase, [Burge] 1031
  - Acetylsalicylic: See also Aspirin
  - acetylsalicylic, stomach derangement from, [Luis y Yagüe] 530
- ACID, Amino: See Amino-Acids
  - Carbolic: See Phenol
  - glycuronic, in urine, [Chiray] 1943
  - hippuric, synthesis of, in body, 1078—E
  - *Intoxication*: See Acidosis
  - lactic, appearance of, in alkalosis, 657—E
  - marked tolerance of body for acids, 864—E
  - phosphoric, simultaneous determination of sulphuric acid and, in urology, [Pittarelli] 383
  - picramic, as standard in colorimetric determination of nitrogen by Nessler's method, [Egerer & Ford] 1327
  - picric, advantages of, over tincture of iodin for disinfection of skin, [Gibson] 960
  - Salicylic: See also Salicylates
  - sulphuric, simultaneous determination of phosphoric acid and, in urology, [Pittarelli] 383
  - Uric: See Uric Acid
- ACIDOSIS, experimental, mineral metabolism in, [Goto] (46) 70
  - febrile, in scarlet fever in children, [Thomas] 1108
  - in surgery, value and limitations of laboratory studies of, [Crile] (19) 68
  - iodin urine test for, [Mitchell] 896
  - method for titrating bicarbonate content of plasma, [Van Slyke & others] 1641
- ACRID principle of certain plants, [Wiley] 61—C
- ACRIFLAVINE emulsion as wound dressing, [Stowell] 1034
  - paste in gunshot wounds, [Tubby & others] 899
- ACROMEGALY plus diabetes, [Labbé & Langlois] 1796, [Labbé] 1943
  - without pituitary tumor, [Yamada] 1115
- ACTINOMYCOSIS, false, [Gougerot] 967
- ADALIN, 1696
- ADDISON'S DISEASE, [Motzfeldt] 1800
- ADENOCARCINOMA of intestine of unusual generalization and with peculiar cystic metastases, [Crowdy] 520
- ADENOIDS, hemorrhage after removal of, [Segui] 1042
  - pituitary insufficiency from, [Caliceti] 1335
  - vegetations, semicentennial of first publication on, [Schmiegelow] 1652
- ADENOMA of thyroid, cardiac arrhythmias of atrial origin occurring in patient with focal infections and, [Barker & Richardson] 827
  - prostatic, bacterial content of prostate and relation to, [Rosen] 1703
- ADENOMYOMA of uterus, frequency of, [MacCarty & Blackman] 960
- ADIPOSIA dolorosa, [Cecikas] 615, [Mingazzini] 1111
- ADRENALIN: See Epinephrin
- ADRENALS: See Suprarenals
- ADVERTISING, absence of "patent medicines" in advertising mentioned by reputable newspapers, 868—E
  - as physician, prosecution for, 1637—Ml
  - cheap but effective, indirect method, through physicians, 1079—E
- ADVERTISING in International Journal of Surgery, 1372—E
  - modern, and nostrum evil, [Cramp] 67—ab
  - of therapeutic agents, 45—E
  - patent medicine, 1692
  - quackish, 1468—E
  - unethical, 1725—ab
- AEROPHAGIA, minor signs of, [Levin] 1578
- AEROPLANE ambulance, [Sharpe] (26) 68, 811, [Strong] 1188
  - radio-surgical, 1092
  - transport of wounded by, 743, 1015
- AGAR, standard, for estimation of bacteria in milk, efficiency of, [Sears & Case] 603
- AGGLUTINATION and opsonic action, [Bond] 524
  - inhibition of, by fresh serum, [Dikshoorn] 1880
- AIR conditioning in home, 370
  - contamination of, in war vessels, causes of, [Kimura] 1329
  - Service Division of Office of Surgeon-General discontinued, 942

  Roentgen-Ray Society to meet, 1308
AMETROPIA, old time victim of, and modern instance, [Gardiner] *1439
AMINO-ACIDS and bacteria, 578—E
  dependence of milk secretion on, 364—E
AMMONIA excretion and gastric secretion, 122—E
AMNESIA, feigned, as defense reaction, [Price & Terhune] *565
AMNIOTIC liquid of animals, biologic relation of diastase ferment between maternal blood, *fetal* blood and, [Kito] 1870
AMPULES with visible index of sterilization, [Cambronero] 1651
AMPULLA of Vater, cancer of, [Ristori] 1261
AMPUTATIONS as war disabilities, 1373—E
  improved technic for, [Phocas] 380
  plastic motor operation on arms, [Chiasserini] 529
  plastic motor surgery, [Bernard] (49) 77, [Arana] (107) 153, [Hoessly] 314, [Arana] 316, [Pellegrini] 834, [Vanghetti] 1040
  stumps, Chiasserini] 1334
AMYL NITRITE inhalations in diagnosis of presystolic murmurs, [Benjamin & Brooks] *707
ANACHLORHYDRIA and apepsia, [Ramond] 1576
ANAEROBES, lactose, fermenting, differentiation of, from B. coli, [Kahn] 603
  obligative, selective elimination of hay bacillus from cultures of, [Hall] *274
ANALGESIA: See Anesthesia
ANAPHYLATOXINS, research on, [Fischer & Kantor] (102) 232
ANAPHYLAXIS: See also Immunity
ANAPHYLAXIS and relation to diatheses common to infancy and childhood, [Schlutz & Larson] 756
  anaphylactic shock and coagulation of blood, [Bulger] (61) 70
  anaphylactic shock, intravenous injection of antiserum to prevent, [Lewis] *329
  cellular, perfusion experiment in study of, [Larson & Bell] 961
  disturbances due to, acute and chronic, treatment of, [Danysz] 1707
  induced anti-anaphylaxis and atropin as protection against acute arsphenamin reactions, [Stokes] *241
ANATOMY, comparative microscopic, of vertebrates, [Osawa] 1948
  comparative, of otoliths, [Quix] 1948
  old nomenclature preferred, 1014
ANEMIA and infectious jaundice, [Ribadeau-Dumas & Nicolas] 966
  aplastic, [Schneider] (22) 142, [Parkinson] 1396
  aplastic, unusual case of, [Smith] 959
  basal metabolism in, with reference to effect of blood transfusion on metabolism in pernicious anemia, [Tompkins & others] 1252
  diagnostic methods in, [Sanford] 1638—ab
  in estivo-autumnal malarial infections, migration of parasites as cause of, [Lawson] 1103
ANEMIA, open air treatment in, due to repeated hemorrhage, [Markoe] 1030
  pernicious, cardiac hypertrophy in, 19 necropsies, [Babot & Richardson] *991
  pernicious, chemistry of, [Kahn & Parsky] 1029
  pernicious, metabolism in, 1846—E
  pernicious, nervous symptoms in, [Woltmann] 1027
  pernicious, side light on problem of, 655—E
  pernicious, treatment of, [Hamman] 1567
  plasma chloride in, [Steinfield] 1253
  with leukemia, [Gram] 1262
ANESTHESIA and eutocia, [Davis] 1566—ab
  chloroform, influence of fasting and various diets on liver injury effected by, [Davis & Whipple] 1792
  chloroform, with tuberculosis, [Olivares] 691
  effects of anesthetics on respiration, [Osterhout] 758
  ether and chloroform and leukocyte count, [Oliva] 1401
  ether, by rectum, [Monod] 381
  ether, influence of hemorrhage, and of plethora from transfusion on pressor effect of minute quantities of epinephrin, [Rous & Wilson] 604
  ether, modification of open method, [Silk] 1941
  ether-oil, by rectum, [Hinojar] 764
  for operations on face and neck, [Dufourmentel] 1038
  general, tremor during, [Rietz] 1948
  in hysteria, [Herrero] 767
  intraspinal, [Frank] 1399
  local, action of, on striated muscle, [Kubota & Macht] 1703
  nitrous oxid-oxygen, for cesarean section and obstetric operations, [McKesson] 522
  organic and functional, diagnosis between, [Williamson] 1331
  procain, 1022
  regional, [de Mendonca] 1502
  spinal, [Rocher] 902
  spinal, elimination of procain after, [Achard] 1876
  spinal general, [Riche] 1707
  substitution of air for oxygen in, [Fryer] 831
  surgical, lacrimal gland secretion in, [Rutherford] 1794
ANESTHETISTS in hospitals, [McMechan] 367—C
ANEURYSMS, aortic, ruptured, in childhood, [Bronson & Sutherland] 608
  arteriovenous, [Chevrier] 613
  arteriovenous, of popliteal vessels, 2 cases of, [Pybus] 1793
  arteriovenous, results of treatment of, 293
  of left auricle, [Lutembacher] (29) 149
  of right ventricle following trauma, fatal case, [Curfman & Fuller] *1673
  racemose, on head, [Noordenbos & de Jong] (123) 154
  syphilitic, popliteal, [Filadoro] 969
ANGINA pectoris, extracardiovascular *causes* for, [Bohan] 1938—ab
  Vincent's: See *Vincent's Angina*
ANILIN, rather than nitrobenzene as *poison* in shoe dye, [Hudson] 747—C
ANISE, *poisonous*, 1309, [Tonina] 1651, 1799
ANKYLOSTOMIASIS: *See Uncinariasis*
ANOPHELINES, susceptibility of, to malarial *infection* in Netherlands India, [Swellengrebel & others] 1712
ANTHELMINTICS, 1228—E
ANTHRAX, 1855
  Anti-Anthrax Serum, 1136
  at Camp Dodge, 3 cases with bacteriologic and blood studies, [Dennett] *270
  at Embarkation Hospital, Newport News, [Amory & Rappaport] *269
  contracted from shaving brush, court awards damages for death resulting from, 1090
  enteritis due to, morbid anatomy and [illegible] Camp Dodg[illegible]
  in soldier, [illegible] due to infection by shaving brush, [Norton & Kokman] *1123
ANTHRAX, local use of antianthrax *serum* in, [Regan] *1724
  neo-arsphenamin in, [Gsell] (55) 77
  prevention of, 1239, 1631
  vaccination against, [Rossello] (100) 232
ANTIBODIES in fetus, [Sherman] 1702
ANTIMENINGOCOCCUS Serum, 1615
  standardization of, [Amoss & Marsh] (87) 146
ANTIMONY *tartrate* in bilharziosis and tachycardia, [Christopherson] 1574
ANTIPNEUMOCOCCUS Serum, 1463
ANTIPYRIN, 1223—T
  salicylate, idiosyncrasy *to*, [de Bellard] (103) 152
ANTISERUM, production of specific antisera for infections of unknown cause and against agent causing chicken sarcoma, [Rous & others] 895
ANTITETANUS Serum: see Tetanus
ANTITOXIN, *Diphtheria*: See Diphtheria Antitoxin
  production of, [Sordelli] (98) 232
  Tetanus: See Tetanus Antitoxin
ANTIVIVISECTIONISTS attack Red Cross, 280—E
  legislation proposed by, 1780
ANURIA after unilateral nephrectomy, [Frank] 1392
ANUS, artificial, treatment of, [Guérin] (55) 229
  fistula in, and hemorrhoids, treatment of, [*Mayo*] 601—ab
  fistulas *of rectum and, tuberculous*, [Hill & *Landsman*] *860
AORTA, radiography *of*, [Mougeot] 527
AORTITIS, syphilitic, early recognition of, [Brown] 520
APEPSIA and anachlorhydria, [Ramond] 1576
APHONIA, hysterical, associated with *latent syphilis*, [*Wolf* & Breeding] *639
  war, treatment of, [Garel] 1332
APPARATUS: See *also Instrument*
APPARATUS, fracture and orthopedic *table to* aid in treatment of fractures *by open* or *closed* method, [McKenna] *861
  pressure, and spinal puncture needle, [*Levinson*] *344
  simple infusion *drop* tube, [Pomeroy] *994
  simple method *of giving* intravenous infusions, [Bluemel] *993
  simple shaker for hemocytometer pipets, [Putnam] *571
APPENDICECTOMY in Colombia, [Castro] 1650
APPENDICES epiploicae, torsion of, [Hunt] 756

  pulmonary, [Thomson] 453
SPIROCHETURIA and influenza, [Maclaud & others] 763
SPITTING in spreading disease, [Taliaferro] 608
SPLANCHNOPTOSIS, [Clark] 1649, [Bonifield] 220—ab
SPLEEN, nonparasitic cysts of, [Lambert] 756
  rupture of, [Masci] 315
  rupture of, hypertrophic, by indirect violence, [Rogers] *1615
  rupture of, subcutaneous, [Walker] 828
  torsion of displaced, [Petridis] 1797
  torsion of pedicle of, [Kopp] 1337
  tuberculous porphyry, [Van Rijssel] 317
SPLENECTOMY, technic for, [Mérola] 460
SPLENOMEGALY, chronic, Wassermann reaction in, [Weil] 1398
  Gaucher type of, [Carr & Moorhead] *19
  hemolytic, [Ceconi] 1709
  massive syphilitic, variety of, attended by remarkable vascular changes, [Symmers & others] 452
SPLINT, control of upper fragment in high fractures of femur and humerus by new form of, [Lee] 610
SPONDYLITIS, deforming, in relation to sciatica, [Schou] 1652
  post-traumatic, [Cluzet] 1037
  typhoid, [Zerbino] 1112
  typhoid, and hysteric curvature of spine, [Chiray & Roger] 1259
SPONGE, abdominal, extra tag on, [Masson] *1612
SPORES, formation of, and observations on Babes-Ernst's bodies, [Ishiguro] 1329
SPRUE, etiology of pellagra, scurvy and, [Nicholls] 830
SPUTUM, albumin in, [Durand] 1400
  tubercle bacilli in, examination for, [Dixon] 684
  tubercle bacilli isolated from, virulence of, [Corper] (59) 70
STAINING of bacteria in tissues for bacteriologic study of pneumonic foci, [Sato] *1365
  vital, improved technic for, [Roman] 382
STAMMERING, physiology of, 1617—E
  plethysmographic study of shock and, [Robbins] 1325
  vocal gymnastics in, 1225—ab
STAPHYLOCOCCEMIA simulating typhoid with relapses, [Baccarani] 1194
STAPHYLOCOCCUS aureus septicemia complicating influenza in Malta, [Patrick] 684
  cultivation of, on previously vaccinated culture mediums, [Carpano] 528
  vaccines, 863
STARCH granules injected into rabbit's vein and tissue, fate of, [Okazaki] 1192
  in fasting stomach, [Wijnhausen & Lubbers] (130) 233
STATE board examinations, statistics of, 1157—E
  board statistics for 1918, 1137
STATISTICS, clever use of, by drugless healers, 731—E
STERILITY, operation for production of, [Cupler] 897
  thyroid, [Giacobini] 1651
STERILIZATION: See also Disinfection
STERILIZATION of women when operating for tubercular peritonitis, [Carstens] (18) 141
STETHOSCOPE, differential, 1563
STEVENS CONSUMPTION CURE, 1018—P
STOMACH, absorption of water from, 1634
  cancer of, [Perez] 1877
  cancer, latent, [Dunet & David] 1258
  cancer, radiologic diagnosis of, [Guillén] 1878
  cancer, 3 cases with no recurrence 5 years after operation, [Douglas] 453
  cancer, urobilinogen in differential diagnosis of, [Scholz] 1499
  cancers in rectum and, false, [Blanc Fortacin] 1113
  chemical research on, [Landolph] 766
  dilatation of, from lack of resting periods, [Hayem] 1192
  dilatation of, postoperative, [Copello] 1879
  disturbances after salicylic medication, [Luis y Yague] 530
  false gallstone in, [Bernales] 1040
  fasting, gastric juice in, [Ramond & Robert] 1035
  fasting, starch in, [Wijnhausen & Lubbers] (130) 233
  foreign bodies in, [Callister] 1030
  functioning, influence of quinin on, [Baufle] 380
  hernia of, from stab wounds, successfully reduced with recovery, [Booth] *937
  hypomotility, opaque meal vs. stomach tube in diagnosis of, [Levy] (21) 142
  in cholelithiasis, [Wessel] (137) 82
  intussusception of, [Fabricius-Møller] 767
  measurement of size and contracting power of, [Le Noir & Gaultier] 1795
  myomatous tumors of, [Nassetti] 834
  operations, after-results of, [Stretton] 454, [Schwyzer] 1254
  operations on intestine and, aseptic, [Gudin] 1399
  pain in, with appendicitis, [Roux] 456
  physiology of; hunger and appetite in pulmonary tuberculosis, [Meyer] (45) 143
  polyposis of, [Balfour] 1494
  secretion and ammonia excretion, 122—E
  secretion, chemistry of, [Landolph] (117) 81, [Usobiaga] 530
  secretion, stimulation and inhibition of, following subcutaneous administration of certain organ extracts, [Rogers & others] 826
  secretion, test for activity of, [Leeper & Binet] 1943
  spiral bodies found in walls of, [Terada & others] 832
  syphilis of, [Azémar & Lacapère] 1577
  syphilitic tumors in intestine and, diagnosis of, [Bard] 762
  tube, [Martinez] 1946
  tuberculosis of, case of multiple miliary tubercles, [Friedman] *101
  tumors, plea for early recognition of, [Kessler] 1936—ab
  ulcer after gastro-enterostomy, [Carnot & others] 1110
  ulcer, differential diagnosis of peptic ulcer, [Cheney] *1429
  ulcer, indirect operative treatment of, [Alvarez] 1196
  ulcer, medical treatment of, [King] 1869—ab
  ulcer of duodenum and, perforated, [Hertz] 386
  ulcer of duodenum and, surgical treatment of, [Finochietto & Vaccarezzo] 905
  ulcer of duodenum and, treatment of, [Odriozola] 1649
STOMACH ulcer, operative treatment of, [Pauchet] 456
  ulcer, pathogenesis of, [de Langen] 1042
  ulcer, puzzle of, [Lynn] 1248—ab
  ulcer should be resected, [Carnot] 456
  ulcer, surgical treatment of, [Murdy] 1869—ab
  ulceration of, simple, [Huerta] 532
STOOL: See Feces
STRABISMUS, convergent, treatment in children, [Cilleruelo] 1946
STRANGE'S RHEUMATIC REMEDY, 59—P
STREPTOCOCCUS, experimental production of symptoms and lesions simulating those in influenza with streptococci isolated during pandemic, [Rosenow] *1604
  hemolyticus and influenza, [Medalia] 1871
  hemolyticus and tonsils, 1295—E
  hemolyticus in faucial tonsil and their significance as secondary invaders, [Pilot & Davis] 1105
  hemolyticus in war wounds, [Bunce & others] *782
  hemolyticus in milk, [Davis] (67) 70
  hemolyticus, serologic study of strains isolated during epidemic at Camp Wadsworth, [Hamilton & Haynes] *272
  hemolyticus of human bovine types, use of final hydrogen-ion concentration in differentiation of, [Avery & Cullen] 604
  hemolyticus with special reference to acute respiratory infections, [Davis] *319
  infections at Camp Custer, with reference to influenza and other antecedent infections, [Blanton & others] *1520
  infections of lungs in British Army, [Wilson] 1107
  infections, susceptibility of convalescents from measles to, [Levy] 1107
  meningitis, acute, with recovery, [Weaver] *1362
  of actinomyces-like granules of tonsils, [Pilot & Davis] (68) 70
  partial tension, and vaccine preparation, [Oliver & Perkins] 1702
  pleomorphic, [Sherwood & Downs] 679
  recovered from sick and wounded soldiers in France, studies on, [Malone & Rhea] 1191
  septicemia, [Rathery & du Castel] 1332
  sore throat, contact infection vs. milk-borne infection in, 1468—E
  sore throat with surgical complications, hospital epidemic of, [Keegan] *1434
  vaccination against, [Levaditi] 902
  Vaccine, 1136
  viridans, atypical form of, [Zingher] 1020—C
STROPHANTHIN, action of, on living cat's heart, [Levine] 1492
  treatment with, in series, [Lankhout] 1532
STRYCHNIN, antitetanus serum neutralizes, [Londini] (82) 230
  cumulative action of, 367
STUDENTS, American and French, fraternizing of, 1384
  American, at French universities, 878
  American, at University of Bordeaux, 1556
  Corps, service of, acknowledged, 1548
  interchange of professors and, 741
  medical, association of, 1855
  medical, demobilizing, 437
  medical, in Peru, 1307
  medical, Parisian, association of, 587
  medical, supply of, 1092
  medical, too many, in Austria, 1239
  medical, work of, during epidemic, 586
  protection of, in dissections and laboratory work, 1854
  ratification of credits, 879
STYPTIC, good? 577—E
SUBMAXILLARY GLAND, automatic and bloodless method of recording volume-flow of blood, [Gesell] 521
SUBTROCHANTER fracture, reduction of, [Costantini & Vigot] 457
SUGAR and urea in cerebrospinal fluid, [Dumolard & others] 1035
